### Unraveling Smell

L. Buck; Howard Hughes Medical Institute, Fred Hutchinson Cancer Research Center, Seattle, WA

Odorants are detected by ~1000 different odorant receptors (ORs), which are located on olfactory sensory neurons in the nose. Our studies show that ORs are used combinatorially to detect different odorants and encode their unique identities. To explore how the nervous system translates odorous chemicals into perceptions, we asked how inputs derived from different mouse ORs are organized as signals travel from the nose to the olfactory bulb and then the olfactory cortex. In the nose, each sensory neuron expresses a single OR gene. Neurons with the same OR are dispersed in the nose, but their axons converge in a few glomeruli at two fixed locations in the bulb. The result is a stereotyped sensory map in which inputs from different ORs are segregated in different glomeruli and relay neurons. In the olfactory cortex, inputs from one OR are targeted to clusters of neurons at specific sites, creating a stereotyped map unrelated to that in the bulb. In contrast to the segregation of different OR inputs seen in both the nose and bulb, it appears that different OR inputs overlap extensively in the cortex and single neurons receive combinatorial inputs from multiple different ORs. Using c-Fos as an indicator of neuronal activator, we found that different odorants elicit different, but partially overlapping, activation patterns in the cortex. The representation of each odorant is composed of a small subset of sparsely distributed neurons. Quantitative analysis of the odor representations suggests that cortical neurons may function as coincidence detectors that are activated only by correlated inputs from different ORs.

### Discovery-Driven Research: A New Frontier in the Biological Sciences

C. Fraser; The Institute for Genomic Research, Rockville, MD

The application of large-scale approaches to the study of biological questions has produced a fundamental change in the way that we approach scientific discovery. In this new era, high-throughput technologies are providing enormous amounts of new data and computational biology is allowing us to make links between genome sequence and biological processes and function. The ultimate goal of such big science is to achieve a predictive understanding of biology.

## Quantitative Studies of Cell Signaling Networks (3-4)

3

### The Deeper Correlations: Single Cell Measures of Kinase Signaling for Mechanistic and Clinical Analyses

G. Nolan; Microbiology/Immunology, Stanford University, Stanford, CA

Intracellular assays of signaling systems has been limited by an inability to correlate functional subsets of cells in complex populations based on active kinase states or other nodal signaling junctions. Such correlations could be important to distinguish changes in signaling status that arise in rare cell subsets during functional activation or in disease manifestation. Simultaneous detection of activated kinases and phosphoproteins in simultaneous pathways in subpopulations of complex cell populations by multi-parameter flow cytometric analysis allows identification of signaling cascades for disease states by ordering of kinase activation and phosphoprotein status in signaling hierarchies. Importantly, we demonstrate that ordering of these activations requires multiple interrogations of cells, and that the networks discovered are reflective of deeper correlations. Using Bayesian Network analysis (a form of machine learning) one can infer pathway connectivity in an automated fashion, allowing for high throughput derivations of signaling system networks graphs in PRIMARY CELLS. The approach has powerful applications in mechanistic understanding, drug screening, and patient stratification for prediction of disease outcome in cancer, autoimmunity, infection, based on signaling network status. ### Systems Biology of Cytokine Signaling in Human Cells

P. Sorger, D. Lauffenburger, K. Janes, S. Gaudet, J. Albeck, B. Schoeberl; Department of Biology and Biological Engineering, Massachusetts Institute of Technology, Cambridge, MA

Cytokines and their receptors activate complex signaling cascades to regulate cell proliferation, death and differentiation. We seek to develop quantitative, mechanistic models that describe cytokine-induced signaling with an eye to understanding cell-type variation and the differences between healthy and diseased states. We focus on decisions controlled by pro-apoptotic cytokines such as Tumor Necrosis Factor (TNF) and TRAIL and pro-survival cytokines such as EGF and the insulin-like growth factors (IGF). By mining a compendium comprising ~10,000 measurements of signal protein activities elicited by cytokines individually and in combination we can construct both statistical and physicochemical models. Classifier-based regression has been particularly helpful in establishing that cells respond to TNF directly, via activated TNF receptor, and indirectly via autocrine circuits involving transforming growth factor alpha (TGF- α), interleukin-1α (IL-1α) and IL-1 receptor antagonist (IL1-ra). These cytokines participate in a three-part autocrine loop that plays out over at least 24 hr and adds sequential layers of pro and anti-apoptotic signaling that sets cell death at a self-limiting level. Experimental work to date has been in human tumor cells. However, it seems highly likely that TNF-triggered autocrine cascades will differ from one cell type to the next. We are currently attempting to compare diseased and normal primary cells from breast and connective tissue. One interesting initial finding is that the logic of the TNF-TGF-IL-1α- IL-1ra cascade can be re-wired in some cell types by inflammatory cytokines such as interferons. There is much interest in the role of intracellular crosstalk among signaling circuits. We propose that that time-dependent crosstalk among synergistic and antagonistic autrocrine circuits may equally important. Morevoer, it should be easier to modulate the activity of autocrine than intracellular loops thanks to the increasing range of protein-based therapeutics available to target cytokines and their receptors.

### Columbia University's Summer Research Program for Secondary School Science Teachers

S. C. Silverstein; Dept Physiology/Cell Biophys, Columbia Univ Coll Phys & Surg, New York, NY

Concerns about the quality of secondary science education stimulated me in 1990 to found Columbia's Summer Research Program (www.scienceteacherprogram.org). The program's purpose is to increase student interest and achievement in science by improving the quality of science instruction. To this end, Columbia's program provides secondary school science teachers with paid fellowships that support their participation in life and physical science research laboratories for two consecutive summers under the guidance of Columbia faculty. To date, 202 teachers have participated in the program. At ASCB's 2004 Education Forum, I reported that 8.4% more students in classes of participating teachers pass a NY State Regents exam in science than students studying the same subject in classes of non-participating teachers in the same school. This is objective evidence that teacher participation in Columbia's program has a significant positive impact on student achievement in science. The present value of this increase in Regents science exam pass rate is $11,782 per teacher in school costs saved annually, and $32,885 per teacher in additional tax revenues generated annually, yielding total annual economic benefits of each teacher's participation in Columbia's program that are 3.4-fold greater than the program's annual cost per teacher. **Policy implications of these findings:** A national investment of $75 million annually could support similar programs at 250 U.S. medical schools and research universities, while returning over $220 million annually in school costs saved and tax revenues generated. If each of these 250 programs enrolled 10 new science teachers annually, over 10 years they could provide science work experiences for 25,000 science teachers, approximately half the current membership of the National Science Teachers Association.

## Prokaryotic Origins of the Cytoskeleton (6-8)

6

### Bacterial tubulin homolog FtsZ

H. P. Erickson; Department of Cell Biology, Duke University Medical Center, Durham, NC

FtsZ is the major cytoskeletal protein in bacterial cytokinesis. When viewed by light microscopy it appears as a "Z ring" in the center of the cell. The Z ring constricts to divide the cell, disassembles during the constriction and then reassembles in the daughter cells. The substructure of the Z ring has not been visualized by EM, but we have turned to in vitro studies to deduce it. FtsZ assembles into short, single-stranded protofilaments (pfs), which are structural homologs of the tubulin protofilaments that make the microtubule wall. We have developed fluorescence techniques to study the kinetics of initial assembly and subunit turnover at steady state. FtsZ assembly is cooperative, showing a weak dimer nucleus and a critical concentration. (It is an enigma how a single-stranded pf can assemble cooperatively.) The assembly is very dynamic - pfs are turning over with a half time of 8 sec at steady state. The subunit turnover is regulated by GTP hydrolysis, and may involve a mechanism like microtubule dynamic instability. We believe that the Z ring in vivo is constructed from these dynamic pfs. This must involve a lateral association (the mechanism for this is unknown) and attachment to the membrane. FtsZ is tethered to the membrane by FtsA, a bacterial actin homolog. We used FRAP to determine the assembly dynamics of the Z ring in vivo. It is turning over with a half time of 8 sec, just as we determined in vitro. This is the most rapid cytoskeletal dynamics known. An important question is what generates the force of constriction? We have found in vitro that FtsZ can form curved pfs, which are equivalent to tubulin rings. The straight-to-curved pf conformational change is powered by GTP hydrolysis, and may generate the force for constriction.

7

**Dynamics of a DNA-Segregating Cytoskeletal System in Prokaryotes**

D. Mullins, C. Campbell, E. Garner; Cellular & Molecular Pharmacology, University of California, San Francisco, San Francisco, CA

The mechanisms that provide force to segregate bacterial chromosomes are still mysterious. We do, however, understand one important example of bacterial DNA segregation in molecular detail - segregation of the R1 and R100 drug-resistance plasmids. These large (100kb), low-copy plasmids encode genes for antibiotic and heavy-metal resistance and have been isolated from many pathogens. To ensure inheritance by both daughter cells during division, the R1 *par* operon constructs a simple DNA-segregating machine from three components. One of these components, ParM, is related to eukaryotic actins and assembly of ParM into actin-like filaments appears to drive plasmid segregation directly. We find that this simple prokaryotic cytoskeleton exhibits a remarkable collection of activities usually associated with eukaryotic cytoskeletons, including: dynamic instability, processive capping, insertional polymerization, and the ability to generate force. We also find that R1 plasmid segregation is a dynamic process in which assembly of unstable ParM filaments induces plasmids to oscillate rapidly from pole to pole of the cell producing a dynamic rather than static bipolar distribution. Our results indicate that the assembly dynamics of prokaryotic cytoskeletal systems are important to their cellular function and that the prokaryotic systems also make use of mechanisms similar to those of the eukaryotic cytoskeleton to establish long-range order and to move intracellular cargo.

8

**The Bacterial Cytoskeleton and Cell Shape**

C. Jacobs-Wagner,[1] N. Ausmees,[2] G. Charbon,[1] M. Cabeen[1]; [1]Molecular, Cellular & Developmental Biology, Yale University, New Haven, CT, [2]Uppsala University, Uppsala, Sweden

Similarly to eukaryotic cells, prokaryotic cells come in a variety of shapes. In eukaryotes, the cytoskeleton, which is made of microtubules, microfilaments and intermediate filaments, constitutes an internal framework that is essential for the maintenance of cell shape. For decades, it was thought that the external cell wall was the sole determinant of cell shape in bacteria. It is now apparent that bacteria also possess an actin-like cytoskeleton made of MreB and that this cytoskeleton is involved in determining rod cell morphology. Our laboratory has recently discovered a prokaryotic counterpart of intermediate filament (IF) proteins, termed crescentin. Crescentin is a fibrous protein with a tripartite domain architecture similar to that of metazoan IF proteins. Purified crescentin self-assembles spontaneously into ~10 nm wide filaments in vitro without exogenous energy sources, which is a distinct biochemical property of IF proteins. The function of crescentin is required for the characteristic crescent shape of *Caulobacter crescentus* as cells lacking crescentin lose their curvature and adopt a straight-rod cell morphology. Consistent with its role in cell curvature, crescentin forms a filamentous structure along the inner cell curvature of wild-type cells. Localization and proper organization of the crescentin cytoskeleton is dependent on the bacterial homolog of actin, MreB, indicating that MreB also plays an active role in cell curvature.

**Still Waters Run Deep: Investigations into the Quiescent State in Yeast**

M. Werner-Washburne; Department of Biology, University of New Mexico, Albuquerque, NM

My laboratory has studied entrance into, survival during, and exit from stationary phase in yeast for the past 17 years. Previously, yeast and other microbes were thought to lack a true $G_0$ phase, because budded cells were always present in stationary-phase cultures. We have recently isolated two distinct cell populations from yeast stationary-phase cultures that contain very different cell types. We have concluded from our analysis that one fraction contains quiescent ($G_0$) cells and the other non-quiescent cells. The quiescent cells are generally the last cells formed after yeast cells exhaust glucose (the diauxic shift). They are refractile by phase contrast microscopy, unbudded, thermotolerant, and synchronous during exit from quiescence. Strangely, in the quiescent cells only nuclei and vacuoles are visible by EM. Non-quiescent cells contain many more membrane-bound organelles, including ER, Golgi, and mitochondria and lipid bodies and lack glycogen. Both cell types are metabolically active, but non-quiescent cells show a reduced ability to form colonies. We are continuing to characterize these cell types and their formation. The identification and characterization of these cell types provides the basis for ongoing, novel analyses of the quiescent state, asymmetric cell division, and the processes of cell differentiation and aging in yeast.

## Cargo Sorting & Vesicular Transport (10-15)

### An Intramolecular t-SNARE Complex Functions *in vivo* without the Syntaxin N-terminal Regulatory Domain

J. S. Van Komen, X. Bai, B. L. Scott, J. A. McNew; Biochemistry and Cell Biology, Rice University, Houston, TX

Membrane fusion in the secretory pathway is mediated by SNAREs (located on the vesicle membrane (v-SNARE) and the target membrane (t-SNARE). In all cases examined, t-SNARE function is provided as a three-helix bundle complex containing three ~70 amino acid 'SNARE-motifs'. One SNARE motif is provided by a syntaxin family member (the t-SNARE heavy chain) and the other two helices are contributed by additional t-SNARE light chains. The syntaxin family is the most conformationally dynamic group of SNAREs and appears to be the major focus of SNARE regulation. An N-terminal region of plasma membrane syntaxins has been assigned as a negative regulatory element *in vitro*. This region is absolutely required for syntaxin function *in vivo*. We now show that the required function of the N-terminal regulatory domain of the yeast plasma membrane syntaxin, Sso1p, can be circumvented when t-SNARE complex formation is made intramolecular. Our results suggest the N-terminal regulatory domain is required for efficient t-SNARE complex formation and does not recruit necessary scaffolding factors.

11

### Arf1p, Chs5p, and the ChAPs are Required for Export of Specialized Cargo from the Golgi

M. Trautwein, C. Schindler, R. Gauss, A. Spang; Friedrich-Miescher-Laboratorium der Max-Planck-Gesellschaft, Tübingen, Germany

In *Saccharomyces cerevisiae*, the synthesis of chitin is temporally and spatially regulated through the transport of Chs3p (Chitin synthase III) to the plasma membrane in the bud neck region. Traffic of Chs3p from the TGN/early endosome to the plasma membrane requires the function of Chs5p and Chs6p. Chs6p belongs to a family of four proteins that we have named ChAPs for Chs5p-Arf1p-binding Proteins. This novel protein family is conserved throughout fungi and seemed to have arisen by three gene duplication events. We show that all ChAPs physically interact not only with Chs5p but also with the small GTPase Arf1p. A short sequence at the C-terminus of the ChAPs is required for protein function and the ability to bind to Chs5p. Disruption of two members, *Δbud7* and *Δbch1*, phenocopies a *Δchs6* or *Δchs5* deletion with respect to Chs3p transport. Moreover, the ChAPs interact with each other and form higher molecular weight complexes. In addition, they are all at least partially localized to the TGN in a Chs5p-dependent manner. Most importantly, the ChAPs interact physically with Chs3p. We propose that the ChAPs facilitate export of cargo out of the Golgi.

12

### The Role of ARF4 and ARF-GAPs in Rhodopsin Trafficking

D. Deretic,[1] L. Astuto-Gribble,[1] N. Ransom,[1] P. A. Randazzo[2]; [1]Surgery/Ophthalmology, University of New Mexico, Albuquerque, NM, [2]Laboratory of Cellular Oncology, National Cancer Institute, Bethesda, MD

The small GTP-binding protein ARF4, a class II ARF, specifically recognizes and binds to the VXPX-COOH sorting motif of the light receptor rhodopsin. Using a retinal cell-free system, which reconstitutes rhodopsin trafficking in vitro, we have established that the rhodopsin-ARF4 interaction regulates the budding from the trans-Golgi network (TGN) and the incorporation of rhodopsin into the transport carriers (RTCs). RTCs are targeted to the rod outer segment (ROS), a highly specialized subcellular domain of retinal photoreceptors. To test if rhodopsin controls the ARF4-GTPase reaction by regulating the access of an ARF-GAP to ARF4, in this study we sought to identify the ARF-GAP that interacts with ARF4 in retinal photoreceptors. ARF-GAPs containing ankyrin repeats and plekstrin homology domains (AZAPs) were particularly attractive candidates given their known roles in the regulation of membrane trafficking and actin cytoskeleton. By western blotting with specific antibodies, we determined that photoreceptors express high levels of ASAP1, an AZAP that also contains the Src homology domain 3 (SH3), and has a preference for ARF1, a class I ARF, and ARF5, a class II ARF. ARAP1, an AZAP that contains a rho-GAP domain, was detected at lower levels. By confocal microscopy ASAP1 was localized to punctate structures distributed along the photoreceptor microfilaments and in the vicinity of the Golgi/TGN. ARAP1 was particularly concentrated at the outer limiting membrane where the actin cables are anchored. We are currently testing the GAP activity of ASAP1 on ARF4. Since the BAR domain of ASAP1 participates in membrane bending and fission, we are exploring if ARF4-dependent recruitment of ASAP1 to the sites of RTC budding may be the underlying mechanism for the regulation of rhodopsin trafficking by ARF4. Supported by NIH grant EY 12421.

13

### Functional Involvement of Annexin II in cAMP-Induced AQP2 Exocytosis in Renal Cells

G. Tamma, A. Strafino, F. Addabbo, M. Svelto, G. Valenti; Department of General and Environmental Physiology, University of Bari, Bari, Italy

The membrane associated protein annexin II is known to be required for the apical transport in epithelial cells. In this study we investigated the involvement of annexin II in cAMP-induced AQP2 translocation to the apical membrane. RT-PCR performed using degenerated primers revealed the presence of annexin II mRNA transcript in AQP2 expressing renal CD8 cells. Interestingly, annexin II was found in AQP2-containing vesicles immunoisolated from CD8 cells. Consistent with this observation, cell fractionation followed by Western blotting analysis showed that stimulation of CD8 cells with the cAMP-elevating agent forskolin, caused a significant increase of annexin II in the particulate fraction paralleled with a decrease in the soluble fraction. To investigate the functional involvement of annexin II in AQP2 exocytosis the fusion process between highly purified AQP2 bearing vesicles and plasma membrane was *in vitro* reconstructed and monitored by a fluorescence assay based on the dequenching of the lipophilic fluorescent probe octadecylrhodamine B-chloride (R18). We designed a peptide reproducing the N-terminal 14 aminoacids of annexin II and including binding site of the the calcium binding protein p11, a protein required for the formation of a complex with annexin necessary for tightly anchoring the protein to the cortical cytoskeleton. A control peptide having 1000 times reduced affinity for p11 was used as a control. We found that preincubation of cellular fractions with annexin II peptide strongly inhibited the fusion induced by the addition of cytosol. In contrast, the control peptide had no effect on fusion. Together these data demonstrate the association of annexin II with AQP2 containing vesicles and point to a possible functional involvement of annexin II in cAMP-induced AQP2 exocytosis in renal cells.

14

### Rab Coupling Protein (RCP) Regulates the Sorting of Membrane Proteins in Recycling Endosomes

J. J. Burden,[1] E. Schonteich,[2] G. Wilson,[2] R. Prekeris,[2] C. R. Hopkins[1]; [1]Department of Biological Sciences, Imperial College, London, United Kingdom, [2]University of Colorado Health Sciences Center, Aurora, CO

Rab coupling protein (RCP) is a class I member of the Rab11 family of interacting proteins (FIPs), a family characterised by their ability to bind Rab11 via a Rab11/25 binding domain (RBD), and to bind phospholipids via a C2 domain. Through its association with Rab11, RCP has been proposed to play a role in protein recycling. Whilst many proteins, like the transferrin receptor (TfR), have been extensively characterised and shown to faithfully follow this recycling pathway, little is known about the molecular machinery involved in regulating this trafficking route. Using RNA interference and a combination of biochemical techniques and electron microscopy, we have investigated the role that RCP plays in the intracellular trafficking of recycling proteins. By immuno-electron microscopy we have localised RCP to a tubular-vesicular compartment, that can be loaded with endocytosed transferrin-HRP. Depletion of RCP in Hela cells, was found to significantly reduce the amount of internalised transferrin in comparison to control cells, whilst the rate of internalisation of the TfR was unaffected. The reduction in transferrin uptake was accompanied by a reduction in the levels of TfR, suggesting mis-sorting of the TfR away from the recycling pathway towards the degradation pathway. To investigate this further, we used RNA interference to deplete cells of another class I FIP member, Rip11, and found that TfR recycling was not inhibited (see Wilson et al. poster). Interestingly, the co-down-regulation of RCP with Rip11 was able to rescue the effect of RCP down-regulation on the TfR, implicating Rip11 in sorting membrane proteins towards the degradative pathway. Thus, we propose that RCP plays a role in the regulation of TfR trafficking, specifically sorting the receptor from the endosomal compartment towards the plasma membrane and away from the degradative pathway.

15

### Ubiquitin Binding Proteins and Lysosomal Sorting

R. C. Piper, S. Winistorfer, J. McDermott; Physiology and Biophysics, University of Iowa, Iowa City, IA

One of the sorting signals that directs membrane proteins to lysosomes is their post-translational attachment to ubiquitin. Ubiquitin acts as a self-contained sorting signal, which acts at may intracellular locales to ultimately send membrane proteins to the lysosome. Ubiquitin works as a signal for internalization, as a TGN sorting signal and as a signal for incorporating proteins into lumenal vesicles of multivesiclular bodies. In order to understand how ubiquitin sorts proteins to the lysosome, we have focused on identifying ubiquitin-sorting receptors at the TGN and endosomes that bind cargo proteins and guide them to lysosomes. At the TGN, we find that the GGA family of clathrin binding proteins bind ubiquitin via two equivalent motifs within their GAT domains. This binding is required to direct ubiquitinated membrane proteins from the TGN directly to endosomes. We also find that several ubiquitin-binding proteins at the endosome are required for sorting into multivesicular bodies. Among these are the Vps27-Hse1 complex, the ESCRT-I complex and ESCRT-II complex. We show that physical interaction of the Vps27-Hse1 complex and ESCRT-I complex triggers a hand-off mechanism whereby ubiquitinated cargo could be transferred from one complex to the next. Interestingly, however, we find that the ubiquitin binding capacity of the ESCRT-I and ESCRT-II complexes is not required for proper sorting of ubiquitinated cargo into the MVB. Thus, we propose that the ubiquitin-binding function of these complexes is used to help Vps27-Hse1 release from cargo binding and help prevent the Vps27-Hse1 complex from being incorporated into the MVB lumen.

## Cell Biology of the Synapses (16-21)

16

### ProN-cadherin Inhibits Synapse Formation

A. G. Reines, W. Shan, A. W. Koch, D. R. Colman; BTRC, Montreal Neurological Institute, McGill University, Montreal, PQ, Canada

N-cadherin participates in the regulation of synaptic strength and stabilization. This protein is synthesized as a precursor molecule (ProN-cadherin) which has anti-adhesive properties. The Pro domain is thought to be cleaved off in the late Golgi by a furin protease, after which adhesively activated N-cadherin is directed to the cell membrane. We raised an antibody recognizing the ProN sequence, and studied the expression of ProN-cadherin in developing hippocampal cultures. We demonstrated the presence of this immature N-cadherin throughout neuronal differentiation, from 5h to 14 days in vitro. Biotinylation of the proteins on the neuronal surface revealed that a proportion of ProN-cadherin is sorted to the plasma membrane and that the mature/immature N-cadherin ratio on the surface increases as neuronal differentiation progresses. Interestingly, we found that the Pro piece is released into the culture media coincident with its decrease on the plasma membrane. To study the function of ProN-cadherin when expressed on the neuronal surface, we employed a construct in which the endogenous cleavage site was replaced by a factor Xa cleavage site. ProN-cadherin overexpression had a large impact on synapse number, measured as a decrease in the number of synaptophysin and PSD-95 puncta. The same effect was observed when the functional labeling of presynaptic boutons with the FM4-64 dye was analyzed. This effect was partially overcome when factor Xa was applied to the cultures. Our results demonstrate that anti-adhesive ProN-cadherin is expressed in neurons and sorted to the plasma membrane where it may act as a negative regulator of synapse formation. We propose that changes in the ratio of mature/immature N-cadherin on the neuronal surface might be a novel mechanism by which neurons regulate synaptic junction formation.

17

### Immaculate Connections, a Kinesin Motor, is Necessary for Presynaptic Differentiation and for the Transport of Synaptic Components

E. Pack-Chung, D. K. Dickman, T. L. Schwarz; Children's Hospital, Harvard Medical School, Boston, MA

The building blocks of synapses are present within growing axons and are recruited to sites of target cell contact. Thus, the transport of synaptic components, including the proteins of synaptic vesicles and active zones, is necessary for synaptogenesis. The identity and regulatory mechanisms of the molecular motors that move synaptic cargoes, however, remain elusive. We have identified a *Drosophila* gene (named *immaculate connections*) that is required for synaptogenesis. *immaculate connections (imac)* encodes a member of the kinesin 3 family of motors. Mutations in *imac* do not prevent axon outgrowth but prevent growth cones from transforming into synapses. At the embryonic neuromuscular junction, growth cones reach their target muscles but do not mature into synaptic boutons. Thus the development of nmj appears to be blocked just at synaptogenesis. Examination of intracellular transport revealed that the trafficking of synaptic vesicle and active zone components are blocked in

*imac*. These proteins were lacking in *imac* axons and accumulated in the cell bodies. However, post-Golgi vesicles, mitochondria, and cytoskeletal components were properly trafficked in *imac* axons. Interestingly, the absence of presynaptic differentiation in *imac* did not prevent the assembly of postsynaptic components; clustering of postsynaptic receptors and postsynaptic density elements were detected. We thus conclude that Imac is selectively required for the transport of materials for synaptogenesis and that in its absence, presynaptic differentiation fails to transpire. Our data also proves that it is distinct from the motor or motors necessary for axon outgrowth. By bringing synaptic materials into the growing axon, imac permits the rapid formation of functional synaptic connections. The coupling and uncoupling of the motor and its cargo are likely to be important in regulating the formation of synapses.

18

**HIP1 Expression is Required for Normal NMDAR Function: Implications for a Role of HIP1 in Huntington's Disease**

M. Metzler,[1] L. Gan,[1] J. Helm,[1] T. P. Wong,[2] L. Liu,[2] Y. Wang,[2] L. Liu,[1] Y. T. Wang,[2] M. R. Hayden[1]; [1]CMMT, Dept. of Medical Genetics, UBC, Vancouver, BC, Canada, [2]The Brain Research Centre, UBC, Vancouver, BC, Canada

The initial identification of the endocytic protein HIP1 (huntingtin interacting protein 1) resulted from its interaction with the polyglutamine-containing protein huntingtin that, in its polyglutamine-expanded form, causes Huntington's Disease (HD). The interaction between HIP1 and huntingtin is significantly altered following polyQ-expansion in huntingtin suggesting that HIP1 is a possible component of the pathogenic mechanism in HD. In previous studies we have shown that AMPA-induced AMPA receptor (AMPAR) trafficking is blocked in cortical neurons from HIP1 knock-out mice (Metzler et al., 2003). Here, we demonstrate a similar block in NMDA-induced AMPAR endocytosis, and hence the reduction of cell-surface AMPAR expression, in cultured hippocampal neurons from HIP1 knock-out mice. Moreover, the NMDA-induced long term potentiation of AMPAR-mediated synaptic transmission at the CA1 synapses in hippocampal brain slices from HIP1 knock-out mice is significantly reduced compared to wild-type littermates. Results from coimmunoprecipitation and GST-pulldown experiments revealed direct interaction between HIP1 and the NR2 subunit of NMDARs. Furthermore, colocalization between HIP1 and NR2-cointaining NMDARs is observed in primary hippocampal neurons. Most important for our understanding of HD, NMDA-induced excitotoxicity is blocked in neurons from HIP1 knock-out mice. Together, these data provide strong evidence that HIP1 regulates NMDAR function and that this function of HIP1 may be contributing to enhanced excitotoxicity in HD.

19

**Association of an AKAP Signaling Scaffold with Cadherin Adhesion Molecules in Neurons and Epithelial Cells**

J. A. Gorski,[1] L. L. Gomez,[1] J. D. Scott,[2] M. L. Dell'Acqua[1]; [1]Pharmacology, University of Colorado Denver Health Sciences Center, Aurora, CO, [2]Vollum Institute, Howard Hughes Medical Institute, Oregon Health Sciences University, Portland, OR

A-kinase anchoring protein (AKAP) 79/150 organizes a scaffold of PKA, PKC and protein phosphatase 2B/calcineurin that is localized to epithelial adherens junctions and the postsynaptic density of neuronal synapses. Targeting of the AKAP to these subcellular locations requires three N-terminal basic domains that bind F-actin and acidic phospholipids. Here we report a novel interaction of this targeting domain with cadherin adhesion molecules that are linked to actin through β-catenin (β-cat). Mapping the AKAP binding site in cadherins identified overlap with β-cat binding; however, no competition between AKAP and β-cat binding to cadherins was detected *in vitro*. Accordingly, AKAP79/150 exhibited polarized localization with β-cat and cadherins in epithelial cell lateral membranes, and β-cat was present in AKAP-cadherin complexes isolated from epithelial cells, cultured neurons, and rat brain synaptic membranes. Inhibition of epithelial cell cadherin adhesion induced by extracellular calcium switch and inhibition of actin polymerization by treatment with LatrunculinA redistributed intact AKAP-cadherin complexes from lateral membranes to intracellular compartments. In contrast, stimulation of neuronal pathways implicated in long term depression that depolymerize postsynaptic F-actin disrupted AKAP-cadherin interactions and resulted in loss of the AKAP, but not cadherins, from synapses. This neuronal regulation of AKAP79/150 targeting to cadherins may be important in functional and structural synaptic modifications underlying plasticity.

20

**Structural Plasticity with Preserved Topology in a Postsynaptic Protein Network**

T. A. Blanpied,[1] M. D. Ehlers[2]; [1]Physiology, University of Maryland School of Medicine, Baltimore, MD, [2]Neurobiology, Cell Biology, Pharmacology and Cancer Biology, Howard Hughes Medical Institute and Duke University Medical Center, Durham, NC

Multiprotein complexes form structural networks to mediate diverse cellular events including adhesion, signaling, nuclear transport, and intercellular communication. The function of such interconnected protein machines is determined by the spatial positioning and dynamic rearrangements of individual components within the complex. The postsynaptic density (PSD) is a prominent example of such networks. The PSD positions neurotransmitter receptors across from presynaptic sites of neurotransmitter release and links postsynaptic receptors with intracellular signaling cascades. Nearly all molecular theories of learning postulate morphological and molecular alteration of the PSD during plasticity at excitatory synapses. However, despite recent documentation of rapid mobility of receptors near the PSD, there is little known about dynamic behavior of core PSD constituents in the complex. To probe the structure of living PSDs, we have measured their internal dynamics using high-resolution imaging analyses. These experiments indicate that the PSD is assembled as a flexible yet topologically stable matrix on which enduring changes in function can be rapidly encoded. Exchange, addition, or removal of PSD elements can occur at independent matrix coordinates, providing a molecular map for organizing synaptic nanoarchitecture.

21

**Two Types of Endocytic Intermediates at the Periactive Zone of a Central Synapse**

A. Sundborger, N. Tomilin, O. Shupliakov; Neuroscience, Karolinska Institutet, Stockholm, Sweden

Dynamin is the GTPase implicated in fission of vesicles from the plasma membrane. In synapses it is an important component of the protein complex responsible for detaching clathrin vesicles from the presynaptic membrane. It has been shown in *in vitro* studies with isolated membranes and with synaptosomes that GTPγS blocks fission resulting in the accumulation of clathrin-coated pits with elongated necks decorated with dynamin-containing spirals. To visualize dynamin-dependent endocytic intermediates in an intact synapse we microinjected GTPγS into living giant axons in lamprey and studied them using electron microscopy. GTPγS did not alter morphology of synapses at rest. Stimulation of

microinjected axons with action potentials at 5 Hz induced a reduction in the number of synaptic vesicles at active zones and the appearance of numerous endocytic intermediates at periactive zones. Two different classes of intermedients were found at periactive zones: clathrin-coated pits with elongated necks, and membrane invaginations. Coated pits were present only on some of these membrane invaginations. Both were connected to the presynaptic membrane. Spiral-like structures were found at sites of these membrane connections. To investigate if these spirals contain dynamin, axons microinjected with GTPγS we cut along the longitudinal axis and stained with anti-dynamin (DG-1) antibodies using a pre-embedding immunogold technique. An accumulation of gold particles occurred at necks of clathrin-coated pits and at sites of connection of membrane invaginations to the presynaptic membrane. Our results show that two endocytic intermediates, clathrin-dependent and clathrin-independent, are formed at periactive zones during synaptic activity. Thus, in addition to the clathrin mechanism, bulk retrieval of large membrane compartments may occur in intact synapses during neurotransmitter release.

## Differentiation & Cancer (22-27)

22

### Understanding Wnt Signaling in Development and Disease

X. He[1,2]; [1]Children's Hospital, Boston, MA, [2]Harvard Medical School, Boston, MA

Wnt signaling is essential for development and tissue homeostasis. Disruption of Wnt signal transduction causes abnormal embryogenesis and cancers. Using a combination of molecular, biochemical and embryological techniques, we have focused on the mechanism of Wnt signaling in Xenopus embryo development and human cancer. We are particularly interested in how the Wnt receptor complex transduces Wnt signal across the plasma membrane, how the Wnt receptor complex specifies distinct transduction pathways to govern different aspects of embryogenesis, and the molecular composition and logic of these transduction pathways. Protein phosphorylation is pivotal for Wnt signaling. We have characterized two key phosphorylation events in the canonical Wnt/beta-catenin pathway. One is phosphorylation of the Wnt coreceptor, LDL receptor related protein 6 (LRP6). This phosphorylation leads to LRP6 activation and the initiation of Wnt signal transduction. The other is beta-catenin phosphorylation, which results in beta-catenin degradation and is inhibited upon Wnt signaling. **1). The mechanism of phosphorylation and activation of the Wnt coreceptor LRP6.** We have shown that Wnt induces LRP6 phosphorylation at PPPS/TP motifs, and this phosphorylation is necessary and sufficient to trigger Wnt signaling. We have generated antibodies that specifically recognize phosphorylated LRP6. These antibodies are useful tools for detection of Wnt signaling activation in vivo and for identification of kinases involved in LRP6 phosphorylation. I will discuss our recent progress in studying Wnt-induced LRP6 phosphorylation and identifying LRP6 kinases. **2). The mechanism of phosphorylation and degradation of beta-catenin.** We have demonstrated that two kinases, casein kinase 1 (CK1) and glycogen synthase kinase 3 (GSK3), sequentially phosphorylate beta-catenin in a protein complex assembled by the scaffolding protein Axin. I will discuss how Wnt receptor activation may lead to inhibition of beta-catenin phosphorylation, and our attempt to identify other key molecules via in vitro reconstitution.

23

### p21WAF1/Cip1 Mediates Notch1-dependent Suppression of Wnt Expression and Signaling

V. Devgan,[1] C. Mammucari,[2] S. E. Millar,[3] C. Brisken,[4] G. P. Dotto[2]; [1]Cutaneous Biology Research Center, Massachusetts General Hospital, Charlestown, MA, [2]Department of Biochemistry, Lausanne University, Epalinges, Switzerland, [3]Department of Dermatology, University of Pennsylvania Medical School, Philadelphia, PA, [4]Swiss Cancer Research Institute, Epalinges, Switzerland

Besides controlling cyclin/CDK and PCNA activities, $p21^{WAF1/Cip1}$ can directly bind transcription factors and co-activators, modulating their functions. However, the biological significance of these findings has not been established. In keratinocytes, p21 is a direct downstream target of Notch1 activation, and loss of either p21 or Notch1 expands keratinocyte stem cell populations and facilitates tumor development. The tumor suppressor function of Notch1 has been associated with negative regulation of β-catenin signaling, through an unknown mechanism. We show here that Notch1 activation down-regulates β-catenin signaling through suppression of Wnts gene expression, and that p21 is a key mediator of this down-modulation. p21 suppresses Wnts expression independently of the cell cycle, while lack of p21 prevents Notch-dependent suppression of Wnt gene expression and results, both in cultured keratinocytes and in the intact skin *in vivo*, in increased Wnt 4 expression. More specifically, p21 associates with the E2F-1 transcription factor at the *Wnt4* promoter and causes curtailed recruitment of c-Myc and p300, and histone hypoacetylation at this promoter. Thus, p21 functions as a mediator of the negative effect of Notch1 activation on Wnt signaling, by specific down-modulation of Wnt gene expression at the transcription-chromatin level and independently of cell cycle.

24

### Gata-3 is a Critical Regulator of Differentiation in the Mammary Gland and Breast Cancer

H. Kouros-Mehr, Z. Werb; Anatomy, UCSF, San Francisco, CA

A series of breast cancer microarray studies have shown that the transcription factor GATA-3 is strongly correlated with Estrogen Receptor (ER) status, tumor grade and survival. We show here that GATA-3 plays a fundamental role in maintaining the luminal epithelial cell fate in the mammary gland and in breast cancer. We initially identified GATA-3 through a microarray screen as the most highly expressed transcription factor in the mammary gland. Immunostaining revealed that GATA-3 is expressed exclusively in all luminal progenitors and differentiated luminal cells. To determine the function of GATA-3, we crossed floxed GATA-3 mice with MMTV-Cre and WAP-rtTA-Cre lines. Homozygous floxed GATA-3 mice carrying MMTV-Cre displayed runting, progressive alopecia, and a highly defective mammary gland. The mammary glands displayed a near lack of epithelium due to an inability to form terminal end buds. To more closely analyze the function of GATA-3, we crossed the floxed mice with the Tet-inducible Cre line WAP-rtTA-Cre. After short-term (72 hr) administration of doxycycline to adult mice, GATA-3 null luminal cells displayed loss of basal polarity and died within the ductal lumen as single cells. To determine how GATA-3 affects breast cancer progression, we used the PyMT mouse model of breast cancer. We transplanted GFP+ hyperplasias into syngeneic mice to determine when malignant conversion occurred. We found that loss of GATA-3 strongly correlated with loss of tumor differentiation, the progression from adenoma to early carcinoma, and the onset of tumor dissemination into distant sites. Furthermore, overexpression of GATA-3 in primary PyMT tumors was sufficient to induce elements of tumor differentiation. This work suggests that GATA-3 specifies and maintains luminal cell differentiation and suggests that loss of cell fate is a critical event in the malignant progression of breast cancer.

### Six1 Promotes Rhabdomyosarcoma Metastasis through Ezrin

Y. Yu; National Cancer Institute, Bethesda, MD

Rhabdomyosarcoma (RMS), thought to arise from skeletal muscle precursors, is the most common soft-tissue sarcoma in children. Despite recent improvements in long-term survival rates, about one third of RMS patients continue to experience relapses, and the majority of these patients die from disseminated metastatic disease. This is due in large part to our rudimentary knowledge of molecular pathways that dictate metastatic potential. Previously, we employed cDNA microarray analysis of RMS cell lines derived from a mouse RMS model, based on deficiency in Ink4a/Arf and deregulation of the hepatocyte growth factor/scatter factor (HGF/SF)-Met signal transduction pathway, to identify a set of genes whose expression was significantly different between highly and poorly metastatic cells. We discovered that the cytoskeletal organizer Ezrin and the developmental homeoprotein Six1 were key metastatic regulators (Nature Medicine, 10, 175, 2004). We have recently found that Ezrin is a direct transcriptional target of Six1; the Six1 transcription factor can bind to the promoter of the Ezrin gene and regulate its expression. Overexpression of Six1 in RMS cells increases Ezrin protein level, whereas Six1 knockdown by siRNA decreases Ezrin protein. Moreover, blocking Ezrin in RMS cells through siRNA can abrogate the metastatic potential of Six1 in vivo. Therefore, Six1 stimulates metastasis of RMS cells through Ezrin. These data show that Six1 and Ezrin are critical regulators of metastasis in RMS, and provide new mechanistic and therapeutic insights into this pediatric cancer.

### Differentiative State Dependent Transcription and Tumorigenesis Elicited by *MYC*

C. Wu,[1] D. Sahoo,[2] C. Arvanitis,[1] N. Bradon,[1] D. Dill,[2] D. W. Felsher[1]; [1]Department of Medicine, Division of Oncology, Stanford University, Stanford, CA, [2]Department of Computer Science, Stanford University, Stanford, CA

Cancer is commonly associated with the malignant expansion of immature cells. The *MYC* oncogene is a transcription factor that when overexpressed is thought to induce tumorigenesis by causing inappropriate gene expression resulting in cellular proliferation, growth and blocking differentiation. Many *MYC* target genes have been identified; however, which *MYC* target genes are actually required for initiating or maintaining a tumor phenotype is unknown. We have established a transgenic mouse model for conditionally regulating *MYC* expression. By using this system, we have found that even a brief inactivation of the *MYC* oncogene can result in the sustained loss of a neoplastic phenotype. We demonstrated that upon *MYC* inactivation immature osteogenic sarcoma cells differentiated into mature osteocytes and formed bone. Surprisingly, *MYC* reactivation failed to restore a neoplastic phenotype, and instead induced the now differentiated tumor cells to undergo apoptosis. Our results suggest the possibility that the inactivation of the *MYC* oncogene may cause epigenetic changes in tumor cells such that they lose the ability to be tumor cells. We hypothesized that upon differentiation, the tumor cells undergo chromatin remodeling which prevents *MYC* from binding to the promoter regions of the genes that are required to induce or sustain tumorigenesis. Indeed, we have shown by cDNA microarrays that upon *MYC* inactivation that there are a multitude of changes in gene expression and that upon *MYC* reactivation many of these changes are not restored to their previous state. Our results suggest that the transcriptional program elicited by *MYC* depends upon the differentiative state and this may define the ability of *MYC* to induce tumorigenesis.

27

### Multiple Signaling Pathways Control the Maintenance and Differentiation of Somatic Stem Cells in the *Drosophila* Ovary

T. Xie, D. Kirilly, X. Song; Stowers Institute for Medical Research, Kansas City, MO

Stem cells are responsible for replenishing lost cells in adult tissues throughout lifetime. One of the challenges in the filed of stem cells is to identify extrinsic factors that control stem cell self-renewal, proliferation and differentiation. The *Drosophila* ovarian somatic stem cells (SSCs) are responsible for producing epithelial cell-like follicle cells that surround differentiated germ cells in egg chambers, providing a nice model system to study epithelial stem cell regulation. In this system, Hedgehog has been shown by others to be important for maintaining ovarian SSCs (King et al., 2001; Zhang and Kalderon, 2001). Recently, we have shown that Wingless signaling is also essential for maintaining SSCs and that its hyperactive signaling causes abnormal follicle cell differentiation and proliferation (Song and Xie, 2003). Here, we report our recent studies on the roles of BMP and Jak-Stat signaling in SSC regulation by examining marked SSCs defective in these pathways. The marked SSC clones defective in the BMP or Jak-Stat pathway are lost rapidly in comparison with marked wild-type control SSC clones, while hyperactive signaling for one of these pathways disrupts normal differentiation of SSC progeny, causing abnormal follicle cell proliferation. Interestingly, Shh, Wnt, BMP and JAK-STAT signaling pathways have been also shown to be involved in cancer formation and stem cell regulation in mammals. The detailed analysis of the roles of these pathways in SSC self-renewal, proliferation and differentiation will be presented.

## Extracellular Matrix & Signaling (28-33)

28

### Signaling by Thrombospondin-1

J. C. Adams, R. Chakravarti, Y. Hashimoto, M. Valiyaveettil; Department of Cell Biology, Lerner Research Institute, The Cleveland Clinic Foundation, Cleveland, OH

Thrombospondins (TSPs) are conserved, extracellular, multimeric, calcium-binding glycoproteins of animals. In mammals, TSPs function within ECM, at cell-surfaces, and as bridging molecules in cell-cell interactions to regulate cell adhesion, migration, angiogenesis, connective tissue organisation and other cell behaviors. The TSPs of invertebrates may function in development and in specialised ECMs (for TSP reviews, see Int. J. Biochem. and Cell Biol. 36, issue 6, June 2004). In all TSPs, the most highly-conserved region is the C-terminal half, comprising EGF domains, type 3 repeats and a C-terminal, L-lectin-like domain. Our interest is in the molecular processes by which TSP-1 induces cell adhesion, actin organisation and motility. For normal mesenchymal cells, spreading on intact TSP-1 signals the formation of protrusions in which F-actin is bundled by the cross-linking protein, fascin. Cell attachment is mediated by the last three type 3 repeats and L-lectin domain of TSP-1, yet native trimeric assembly is needed to support cytoskeletal assembly and migration. Of the transmembrane adhesion receptors that bind TSP-1, syndecan-1 has a key role in transducing lamellipodial spreading and actin-bundling by fascin. We have established that the V region of syndecan-1

cytoplasmic domain is critical for this activity. Whereas TSP-1-adherent cells maintain the actin-bundling form of fascin which is non-phosphorylated at residue S39, other ECM components such as fibronectin signal fascin phosphorylation through integrin-dependent activation of protein kinase C. Phosphorylated fascin associates with the regulatory domain of protein kinase Calpha and this complex acts to modulate the balance between focal adhesions and protrusions, resulting in alterations to cell motility behavior. These findings demonstrate distinct signaling activities of TSP-1 and uncover a mechanism for intersection with other signaling processes activated by complex ECM.

29

**Thrombospondin 1 induced Akt activation and anoikis resistance**

C. A. Elzie, J. Murphy-Ullrich; Department of Pathology, University of Alabama, Birmingham, AL

Thrombospondin 1 (TSP1) is a matricellular protein that is up-regulated in areas of active tissue remodeling. We previously showed that amino acids 17-35 of TSP1 or a peptide comprised of this sequence (hep I) binds to the receptor co-complex of cell surface calreticulin and LDL receptor-related protein (LRP1), stimulating focal adhesion disassembly and cell motility through activation of PI3K, FAK, ERK and downregulation of Rho signaling. We now show that hep I initiates cell survival signals in mouse embryonic fibroblasts and prevents apoptosis caused by a loss of cell-matrix signals (anoikis). Anoikis is mimicked in cell culture by plating cells on poly-HEMA, which does not support adhesion. Cells on poly-HEMA show increased cleavage of PARP and annexin V staining, indicative of cell death. Addition of hep I to cells reduces PARP cleavage and annexin V staining. Calreticulin is also highly up-regulated in cells plated on poly-HEMA. Since hep I activates PI3K, we investigated whether hep I activates Akt and whether Akt is important for hep I rescue from anoikis. Hep I, the heparin binding domain of TSP1 (Nco1) and TSP1 transiently activate Akt. TSP1/hep I binding to calreticulin is important for Akt activation since a peptide that blocks TSP1/hep I binding to calreticulin and calreticulin null fibroblasts are unable to activate Akt by TSP1, but not by insulin. Adding exogenous calreticulin back to the cell surface restores TSP1-induced Akt activation. An inhibitor of ligand binding to LRP1, RAP, also blocks Akt activation by TSP1. Taken together, the data show that TSP1 binding to calreticulin/LRP1 through its hep I sequence, activates anti-apoptotic signaling. These data suggest that TSP1 plays a critical role in cellular responses to injury and tissue remodeling.

30

**Extracellular Matrix Protein CCN1 (CYR61) Induces Apoptosis in Fibroblasts**

V. Todorovic, C. C. Chen, N. Hay, L. F. Lau; Biochemistry and Molecular Genetics, University of Illinois, Chicago, IL

Integrin-mediated cell adhesion to extracellular matrix proteins is known to promote cell survival, whereas detachment from the matrix can cause rapid apoptotic death in some cell types. Contrary to this paradigm, we show that fibroblast adhesion to the angiogenic matrix protein CCN1 (CYR61) induces apoptosis, whereas endothelial cell adhesion to CCN1 promotes cell suvival. CCN1 induces fibroblast apoptosis through its adhesion receptors, integrin $\alpha_6\beta_1$ and the heparan sulfate proteoglycan (HSPGs) syndecan-4, triggering the p53-dependent activation of Bax to render cytochrome c release and activation of caspases 9 and 3. Neither caspase 8 activity nor *de novo* transcription or translation is required for this process. These results show, for the first time, that cellular interaction with a specific matrix protein can either induce or suppress apoptosis in a cell type-specific manner, and that integrin $\alpha_6\beta_1$-HSPGs can function as receptors to induce p53-dependent apoptosis.

31

**Extracellular Cues Influence Fibronectin Alternative Splicing Through an Intrincate Network of Signaling Pathways**

F. Pelisch, M. Blaustein, L. Quadrana, A. Srebrow; Departamento de Fisiología, Biología Molecular y Celular - Facultad de Ciencias Exactas y Naturales, Laboratorio de Fisiología y Biología Molecular - IFIBYNE, Consejo Nacional de Investigaciones Científicas y Técnicas, Buenos Aires, Argentina

Alternative pre-mRNA splicing is the most important source of protein diversity in vertebrates. Regulation of this process by extracellular cues represents a key event in the control of gene expression. We use mouse mammary cell lines and the fibronectin gene to study the linkage between the cellular microenvironment and the splicing machinery. We found that a laminin-rich basement membrane down-regulates the inclusion of two fibronectin alternative regions, EDA and IIICS, through a JNK-dependent pathway in epithelial cells. We propose that dephosphorylation of ERK is involved in this regulatory process. By contrast, soluble factors from a mammary mesenchymal cell-conditioned medium as well as different growth factors up-regulate their inclusion via PI 3-kinase. The laminin-rich basement membrane blocks the effect of the mammary mesenchymal cell-conditioned medium, extending the already proposed antagonism between these two signaling pathways to the field of alternative splicing. These results highlight the fact that the splicing pattern of a single transcript is the read out of an intricate network of different signaling cascades. SR proteins have emerged recently as much more than splicing regulators and their activity has been associated to different steps along mRNA metabolism. We found that the signaling pathway triggered by soluble factors not only affect mRNA splicing but also alter translation of reporter mRNAs containing a fibronectin EDA exonic splicing enhancer. These effects on splicing and translation are dependent on SR proteins and can be duplicated by over-expressing a constitutively active AKT, a downstream target of PI 3-kinase. These latter results show how SR protein activity is modified in response to extracellular cues leading to a concerted regulation of splicing and translation.

32

**Laminin-5 Beta 3 Chain Promotes Epidermal Carcinogenesis Through Type VII Collagen Binding and Pi3k Activation**

N. Sakai, E. A. Waterman, N. T. Nguyen, B. A. J. Horst, D. P. Veitch, C. N. Dey, S. Ortiz-Urda, P. A. Khavari, M. P. Marinkovich; Epithelial Biology, Stanford University, Stanford, CA

Laminin-5 plays an essential role in epidermal carcinogenesis but the underlying mechanisms remain unclear. To further address this we retrovirally expressed two laminin beta-3 chain truncations, termed Tr1 (deletion domain VI) and Tr2 (deletion domains VI-V-III), in laminin beta-3 negative epidermolysis bullosa keratinocytes. Tr1/Tr2 laminins were properly assembled, expressed at wild type levels and deposited into keratinocyte extracellular matrix. Tr1/Tr2-expressing keratinocytes displayed normal migration and spreading but showed decreased stable adhesion as measured by trypsin detachment assay and showed abnormal localization of actin filaments and focal adhesion components to hemidesmosomes. Despite these adhesive defects, Tr1 cells transformed with Ras and IkBa produced SCC-like tumors after SQ injection to nude mice and showed Matrigel invasion equal to control transformed keratinocytes. In contrast, Ras/IkBa transformed Tr2 cells showed a complete

inability to form tumors or invade Matrigel. Transformed Tr2 cells displayed decreased PI3-kinase activity compared to transformed Tr1 and wild type cells. Retroviral transfer of active PI3-kinase cDNA restored normal matrigel invasion to Tr2 cells. Moreover, PI3-kinase expression completely restored tumorigenesis and tissue invasion to transformed Tr2 cells after SQ injection to nude mice. Transformed type VII collagen null keratinocytes were also shown to have deficient PI3-kinase and invasive activity, which was restored by retroviral transfer of PI3-kinase cDNA. Purified Tr1 laminin (lacking domain VI) bound to collagen VII by solid phase assay in a normal dose-dependent manner, whereas purified Tr2 laminin (lacking domain VI-V-III) failed to bind type VII collagen. These studies suggest that domain VI mediates stable adhesion involving transition of focal adhesions to hemidesmosomes, but this process is dispensable for tumorigenesis. Instead it is the binding of laminin beta-3 domain V-III to type VII collagen which promotes epidermal carcinogenesis through PI3-kinase activation.

33

**CD98hc (SLC3A2) Supports Fibronectin Matrix Assembly by Capacitating Outside-In Integrin Signaling**

C. C. Feral,[1] A. Zijlstra,[2] G. Prager,[1] M. Slepak,[1] M. H. Ginsberg[1]; [1]Dpt. of Medicine, University of California San Diego, La Jolla, CA, [2]Dpt. of Cell Biology, The Scripps Research Institute, La Jolla, CA

The cell-mediated assembly of soluble fibronectin into a fibrillar matrix is essential for vertebrate development. The initiation of matrix assembly involves the binding of soluble fibronectin to high affinity integrins, such as integrin α5β1, which transmit cellular contractile forces to the fibronectin, leading to exposure of matrix assembly sites. In addition to transmitting force to fibronectin, integrins can initiate intracellular biochemical signals, such as activation of Src kinases and Focal Adhesion Kinase (FAK). We have recently found that CD98 heterodimers comprised of a common heavy chain (CD98hc, SLC3A2), and one of several light chains, interact with integrins via the CD98hc moiety and mediate the integrin-dependent activation of FAK and phosphorylation of several Src substrates. We disrupted the CD98hc gene in embryonic fibroblasts and we report here that CD98hc is required for fibronectin matrix assembly, but not for fibronectin biosynthesis. The loss of matrix assembly is not due reduced integrin affinity because the CD98hc null fibroblasts bound soluble fibronectin cell binding domain with the same affinity as wild-type cells and because enforced activation of integrin α5β1 with a monoclonal antibody did not rescue the assembly. CD98hc mutants that restore integrin-dependent biochemical signaling, rescued matrix assembly. In contrast, mutants that fail to associate with integrins or promote integrin signaling failed to reconstitute matrix assembly. Thus, outside in signals, mediated by an integrin-CD98 complex, lead to activation of FAK and Src and promote fibronectin matrix assembly.

## Formins & Arp2/3: Regulators of Actin (34-39)

34

**A Novel Arp2/3-Activating Protein that Interacts with Dynamic Endomembrane Compartments and Microtubules**

N. J. Webb, E. A. Znameroski, M. D. Welch; Molecular & Cell Biology, University of California, Berkeley, Berkeley, CA

The Arp2/3 complex is a central actin nucleating and organizing factor that functions in a variety of processes including lamellipodia protrusion, podosome formation and endocytosis. The activities of the Arp2/3 complex are regulated by a class of proteins called nucleation-promoting factors (NPFs). Mammalian cells express several well-studied NPFs including WASP, N-WASP, and Scar/WAVE1-3, each of which may play a distinct function in regulating actin nucleation in the cell. Given the diversity of NPFs and their important role in regulating actin dynamics, we sought to identify additional uncharacterized members of this protein family. Here we report the identification of a novel class of NPFs comprised of two proteins, KIAA1971 and JMY. Each contains a C-terminal WCA domain that is a conserved feature of NPFs, a central region predicted to form coiled-coils, and an N-terminal domain of unknown function. Our studies show that the recombinant full-length KIAA1971 protein and its WCA domain activate the Arp2/3 complex in vitro, confirming that it is an NPF. To evaluate its cellular function, we analyzed its localization in stably-transfected cells. Interestingly, GFP-KIAA1971 localizes to rapidly moving internal membranes, suggesting a role in endomembrane dynamics. Drugs that perturb actin and microtubule dynamics interfere with the movement of GFP-labeled membranes, implying that both cytoskeletal networks play a role in motility. Surprisingly, we also find that GFP-KIAA1971 colocalizes with microtubules in transiently-transfected cells that overexpress the protein. We mapped the domain of KIAA1971 responsible for microtubule localization to the central coiled-coil region using GFP-tagged N- and C-terminal truncations. Overexpression of this domain causes the bundling and stabilization of microtubules, hinting at a role in microtubule function. In summary, our studies suggest a novel role for NPFs in integrating actin and microtubules with the regulation of endomembrane dynamics.

35

**Reconstitution of N-wasp-dependent Vesicle Motility from Pure Components: Spontaneous "symmetry Breaking" via Stochastic, Localized Activation of the Cdc42/rhogdi Complex**

D. T. Wong, C. Co, J. Taunton; University of California, San Francisco, San Francisco, CA

Actin polymerization at the plasma membrane drives cell motility. A minimal motility medium consisting of 4 purified proteins (actin, Arp2/3 complex, cofilin, and capping protein) has provided a simplified model system with which to study the mechanism of actin-based force generation. Plastic beads uniformly coated with Arp2/3 activators such as ActA or N-WASP break symmetry slowly, by assembling a symmetrical actin gel that eventually ruptures and transforms into an asymmetric, force-generating comet tail. By contrast, in cells and cytoplasmic extracts membrane-bound organelles appear to break symmetry instantaneously. The biophysical mechanism by which this occurs is unknown. Using purified proteins and lipid bilayer-coated glass microspheres, we have developed a novel reconstitution system that integrates guanine nucleotide exchange factor (GEF)-dependent activation of the Cdc42/RhoGDI complex with actin nucleation promoted by N-WASP and the Arp2/3 complex. Upon GEF-mediated activation at the membrane surface, prenylated Cdc42 is released from its soluble inhibitor, RhoGDI. Stochastic, membrane-localized activation of Cdc42 and N-WASP in the motility medium leads to the instantaneous assembly of an asymmetric comet tail, with no evidence for a symmetrical actin gel. In contrast, when lipid-coated beads are pre-activated with Cdc42 and N-WASP and then placed in the motility medium, a symmetrical actin gel forms, similar to plastic beads. Our reconstitution system provides insights into the mechanism by which a localized signal at the membrane can rapidly generate protrusive motility.

36

**Mechanisms of Actin Bundle Formation by Mammalian Formins**

E. S. Harris,[1] I. Rouiller,[2] D. Hanein,[2] H. Higgs[1]; [1]Department of Biochemistry, Dartmouth Medical School, Hanover, NH, [2]Burnham Institute, La Jolla, CA

Formins are a conserved family of actin-associated proteins, with many eukaryotes expressing multiple isoforms. The biochemical properties of several yeast and mammalian formin FH2 domains have been studied in vitro. Formin FH2 domains have the following effects on actin dynamics: 1) accelerating nucleation rate, 2) altering elongation/depolymerization rates, and 3) antagonizing barbed end capping by capping proteins. The potency of each effect varies between formins, reflecting quantitative differences in an apparently similar mechanism centered around barbed end binding by FH2 domains. We have found that a subset of mammalian formins have a fourth activity, filament side binding and bundling. FH2 domain-containing constructs of FRL1, FRL2, and mDia2 can bundle actin filaments, while mDia1's FH2 domain cannot. Filament side binding and bundling is dependent only on the FH2 domain. Filaments bundled by formins are arranged in a predominately anti-parallel orientation. Our results suggest that individual formins may have different mechanisms for bundling. mDia2's bundling activity is not competitive with barbed end binding. Additionally, mutation of a conserved residue in the mDia2 FH2 domain that faces the inside of the FH2 "donut" drastically reduces mDia2's affinity for the barbed end, but has no effect on bundling ability. This suggests mDia2 may bind filament sides through interactions that involve residues on the outside of the FH2 dimer, and are different from residues used for barbed end binding. In contrast, FRL1's bundling activity is competitive with barbed end binding suggesting it may occur through residues on the inner face of the FH2 dimer.

37

**Dynamics of the Formin For3p and Actin Cables in Fission Yeast**

S. G. Martin, F. Chang; Department of Microbiology, Columbia University, New York, NY

How formins are localised and regulated to form dynamic actin structures at the right place *in vivo* is still poorly understood. In the fission yeast *Schizosaccharomyces pombe*, the formin for3p functions at cell tips to assemble actin cables, which are thought to be dynamic bundles of short actin filaments oriented with barbed ends facing the cell tip. Using a for3p-3GFP fusion expressed at endogenous levels, we observed small dots of for3p that stream in linear paths away from the cell tip at a rate of 0.3μm/s. This rate is similar to actin polymerization rates, as measured by imaging actin cable markers. The for3p retrograde movements are dependent on actin cables and on actin binding residues within the FH2 domain of for3p. In addition, we observed anterograde movements of for3p dots towards the cell tips at a significantly faster rate (1.1μm/s), which is consistent with myo52p (myosin type V)-driven movements. Indeed, these anterograde movements are not detected in *myo52* mutants. Further, for3p and myo52p associate with each other in co-immunoprecipations. FRAP studies confirm that for3p is highly dynamic at cell tips. These studies provide a new model for actin cable formation and formin dynamics. We propose that for3p is present and active for actin assembly at the cortex for only seconds. It may then remain bound inactive on the barbed end of the actin filament, where it is carried passively by bulk movement of the actin cable away from the cell tip. Myosin-V directed transport on actin cables may contribute to targeting for3p back to the cell tips. These studies suggest the existence of a dynamic actin assembly machine at the cortex that transiently docks, activates and then releases formins.

38

**Dissecting the Role of mDia2 in Actin Dynamics in Migrating Epithelial Cells**

S. L. Gupton,[1] K. M. Eisenmann,[2] A. S. Alberts,[2] C. M. Waterman-Storer[1]; [1]Cell Biology, Scripps Research Institute, La Jolla, CA, [2]Van Andel Research Institute, Michigan State University, Grand Rapids, MI

Formins nucleate and protect actin filaments from capping, and promote polymerization from fast growing filament ends in vitro, but their role in migrating cells is unknown. Previously, we have used quantitative Fluorescent Speckle Microscopy (qFSM) to define actin-based modules mediating epithelial cell migration: the lamellipodium being the protrusive module and the lamella being the adhesive/contractile module. The actin nucleating complex Arp2/3 is active in the lamellipodium of epithelial cells, but it is unclear where formin proteins are active and how they contribute to actin cytoskeleton remodeling in these modules of migrating cells. To test the hypothesis that mDia2 is involved in actin polymerization in the lamella, we used a combination of FRET and qFSM microscopic assays along with reagents to manipulate mDia activity. To examine where mDia2 interacts with and is potentially activated by different Rho GTPases with respect to these two zones, FRET was employed by expressing CFP-GTPase and YFP-mDia2 fusion proteins to act as donor/acceptor pairs respectively. YFP-mDia2 was bound to CFP-Cdc42 in filopodia at the leading edge and at focal adhesion sites in the lamella. Consistent with a role for mDia2 at these sites, inhibition of mDia2 by microinjection of an antibody that specifically inhibits mDia2-mediated actin nucleation in vitro decreased the amounts of free filament barbed ends at focal adhesions. Expression of an activating subunit of mDia (DAD), an inhibitory subunit of mDia (FH2δN), or microinjection of the inhibitory antibody affected lamellipodium stability and the typical patterns of actin polymerization/depolymerization observed by qFSM in the lamella and lamellipodium of control cells. These changes in actin turnover and movement correlated with inhibition of cell migration, suggesting that proper spatio-temporal activity of mDia2 is necessary for proper actin organization and dynamics and efficient cell migration.

39

**Mechanism of Filopodia Formation Induced by mDia2**

C. Yang,[1] L. A. Czech,[2] S. Kojima,[2] G. G. Borisy,[2] T. M. Svitkina[1]; [1]Department of Biology, University of Pennsylvania, Philadelphia, PA, [2]Department of Cell and Molecular Biology, Northwestern University Medical School, Chicago, IL

Expression of GFP-tagged constitutively active mDia2(ΔGBD) mutant induced filopodia-like protrusions in B16F1 cells with mDia2(ΔGBD) localizing to their tips. These processes frequently had an unusual club-like shape with a thick bundle of unbranched actin filaments in the distal domains, which tapered towards the rear so that a smaller number of filaments formed a thinner bundle in the stalk. Many free pointed ends could be seen in the region of bundle tapering. Depolymerization from these ends apparently was responsible for the club-like shape of mDia2(ΔGBD)-induced filopodia. Kinetic studies showed that initiation of mDia2(ΔGBD)-induced filopodia frequently occurred by sudden appearance of a GFP-positive dot at the cell edge or dorsal surface. While the dot grew in intensity, a filopodial bundle developed at this site. Fusion of two or more mDia2(ΔGBD)-induced filopodia led to formation of larger club-like protrusions. Nascent mDia2(ΔGBD)-induced filopodia contained tapered actin bundles with multiple free pointed ends at the rear. Such structure contrasts the lambda-like shape of normal nascent filopodia, where actin

filament pointed ends are engaged in branch formation in the surrounding network. mDia2(ΔGBD) also localized along the leading edge of some lamellipodia. Such lamellipodia had unusual actin organization and contained numerous long unbranched filaments with free pointed ends. Over time, they usually split into several filopodia, apparently, due to initiation of bundling. Ena/VASP proteins were not required for filopodia formation by mDia2(ΔGBD) as shown by transfection of $MV^{D7}$ fibroblasts lacking all endogenous Ena/VASP proteins. Moreover, over-expressed mDia2(ΔGBD) displaced endogenous or co-expressed VASP from filopodial tips. Together, these data show that constitutively active mDia2 is recruited to the membrane where it induces filopodia by nucleating actin filaments and subsequently protecting their barbed ends from capping. Supported by NIH grants GM 62431 (GGB) and GM 070898 (TMS).

## Nuclear Envelope Functions (40-45)

40

### Insight into the Nucleocytoplasmic Transport Mechanism from Novel Assays for FG-Repeat Requirements and mRNA Export Kinetics

L. J. Terry, S. R. Wente; Department of Cell & Developmental Biology, Vanderbilt University Medical Center, Nashville, TN

Nucleocytoplasmic transport requires interactions between transport receptors, which accompany cargo during transport, and nucleoporins (Nups), which comprise the nuclear pore complex (NPC). Nearly half of the ~30 Nups contain domains of phenylalanine-glycine (FG) repeats, and these FG-Nups constitute critical binding sites for intermediate points in nucleocytoplasmic transport. Using genetic strategies in *Saccharomyces cerevisiae* we generated a collection of strains depleted of higher-order combinations of FG-repeat domains (Strawn *et al.* Nature Cell Biology 2004) and determined that the five asymmetrically distributed FG-repeat domains, creating strain ΔNΔC, are unnecessary for viability and bulk transport. However, symmetrically distributed FG-repeat domains are required in discrete combinations. Although there is a growing body of evidence on the interactions between transport receptors and FG-Nups, the precise mechanism of nucleocytoplasmic transport remains unknown. To gain a better understanding of the transport mechanism, we have utilized FG-repeat deletion strains to study the mRNA transport receptor Mex67p/TAP/Nxf1 and several members of the karyopherin-B family of transport receptors. We have taken advantage of the ΔNΔC strain background to analyze the roles of the symmetric FG-Nups. Further deletions in the ΔNΔC strain resulted in viable more minimal strains, which have served as a powerful tool to identify symmetric FG-repeat domains critical to specific transport pathways while preventing the possibility of compensation by asymmetric FG-repeats. We have screened FG-repeat deletion strains by *in situ* hybridization for poly(A)RNA and have developed an assay to detect the rate of recruitment of Mex67p to NPCs as a measure for mRNA export. Notably, specific FG-repeat deletions cause defects in poly(A)RNA export and impair the recruitment of Mex67p to the NPC. These studies provide insight into the complex series of interactions between FG-Nups and transport receptors required for efficient nucleocytoplasmic transport.

41

### Pml39, a Novel Nuclear-Pore Associated Protein Involved in mRNA Surveillance in Budding Yeast

B. Palancade,[1] M. Zuccolo,[1] S. Loeillet,[2] A. Nicolas,[2] V. Doye[1]; [1]Section Recherche, UMR 144 CNRS - Institut Curie, Paris, France, [2]Section Recherche, UMR 7147 CNRS - Institut Curie, Paris, France

In *S. cerevisiae*, perinuclear improper mRNP retention involves the Mlp1-2 nucleoporins. Here we describe a new yeast protein belonging to this pathway, Pml39 (for pre-mRNA leakage, 39 kDa). *PML39* was identified on the basis of a strong and specific genetic interaction with genes encoding nucleoporins of the Nup84 nuclear pore subcomplex. Like Mlp1 and Mlp2, Pml39 is associated with a subset of nuclear pore complexes (NPCs) facing the chromatin, opposite to the nucleolus. As further established by mislocalization of the GFP fusion and two-hybrid analysis, Pml39 is mainly docked at NPCs through interaction with Mlp1 and Mlp2 N-terminal domains. Functional studies revealed that the *PML39* deletion induces a specific leakage of unspliced mRNAs out of the nucleus, that is not additive to the one exhibited by *mlp1Δ*. In addition, overexpression of a *PML39-GFP* fusion leads to a specific trapping within discrete nuclear domains of mRNAs transcribed from an intron-containing reporter and of the hnRNP Nab2. In a *nup60Δ* mutant, Pml39 is mislocalized together with Mlp1 and Mlp2 in intranuclear foci that also recruit Nab2. Moreover, the temperature-sensitive phenotypes of mutants of mRNPs components such as *GFP-yra1-8* and *ΔN-nab2* were partially rescued by the *pml39* deletion. Thus, *pml39* deletion bypasses the requirement for normally assembled mRNPs, demonstrating that the function of the Pml39 protein is to retain improper mRNPs in the nucleus. Pml39 appears as an upstream effector of the Mlp1/2 pathway, required for the quality control steps occuring prior to the export of mRNAs out of the nucleus.

42

### The Nucleoporin Gp210 is Required for Nuclear Envelope Breakdown

W. Antonin,[1] V. Galy,[2] I. W. Mattaj[1]; [1]Gene Expression, European Molecular Biology Laboratory, Heidelberg, Germany, [2]Unité de Biologie Cellulaire du Noyau, Institut Pasteur, Paris, France

In higher eukaryotes the nuclear envelope is a dynamic structure during cell cycle: It breaks down at beginning of mitosis and reforms around the separated chromatin at its end. During nuclear envelope breakdown (NEBD) nuclear pore complexes are disassembled into nucleoporins being present during mitosis mostly in soluble form. The membranes are at least in mammals reabsorbed into the endoplasmic reticulum and the lamina, which is underlying the inner nuclear membrane in interphase, is disassembled. Although these processes have been known for a long time the molecular mechanisms leading to NEBD are largely unidentified. Using RNA interference in *C. elegans* embryos and antibody inhibition experiments in *Xenopus* egg extracts we show that the nucleoporin gp210 is required for efficient NEBD in both systems. We also confirmed our previous results suggesting that gp210 is not required for nuclear membrane fusion and nuclear pore complex formation at the end of mitosis both in *C. elegans* and *Xenopus* egg extracts (Galy *et al.* (2003), Antonin *et al*. (2005)). This study unexpectedly suggests that gp210 functions in the context of NEBD and indicates that nuclear pore complex disassembly and NEBD are functionally linked.

43

### Lamin A/C Mutation Activates MAP Kinase Signaling Pathways in Hearts of an Animal Model of Autosomal Dominant Emery-Dreifuss Muscular Dystrophy

A. Muchir,[1] P. Pavlidis,[2] A. J. Herron,[3] T. Arimura,[4] G. Bonne,[5] H. J. Worman[1]; [1]Departments of Medicine and of Anatomy and Cell Biology,

Columbia University College of Physicians & Surgeons, New York, NY, [2]Department of Biomedical Informatics, Columbia University College of Physicians & Surgeons, New York, NY, [3]Institute of Comparative Medicine and Department of Pathology, Columbia University College of Physicians & Surgeons, New York, NY, [4]INSERM U582, Institut de Myologie, Groupe Hospitalier Pitie-Salpetriere, Paris, France, [5]INSERM U582, Institut de Myologie, Groupe Hospitalier Petie-Salpetriere, Paris, France

Mutations in LMNA gene encoding lamins A and C, two intermediate filaments of the nuclear envelope, cause diseases affecting various tissues, including striated muscle and the aging process. We have created a lamin A/C H222P mutant knock-in mouse model of Emery-Dreifuss muscular dystrophy, which develops skeletal muscle disease and cardiomyopathy. In the present study, we determined the effects of this mutation on signaling pathways that may be involved in the development of cardiac abnormalities. We analyzed genome-wide gene expression profiles in hearts from mutant and control mice using Affymetrix GeneChip® Mouse Genome 430 2.0 Array. To do not dilute our analysis with genes that are common to other cardiomyopathies, hearts were analyzed at an early stage before the appearance of clinical symptoms or gross pathological abnormalities. To analyze the data, we applied statistical methods that included ANOVA (P-value <0.05) and a false discovery rate analysis adjusted to a stringent 5% level. Statistically significant abnormal expression of genes related to the stress activated MAP kinases molecular pathway were present in both H222P+/- and H222P-/- hearts and confirmed by real-time PCR. Using immunoblot analysis, we then showed increases in ERK1/2, JNK1/2 and p38, MAP kinases that have been previously implicated in cardiac hypertrophy and heart failure. We also showed an increased content of several sarcomere proteins (actin, myosin, troponin T), angiogenesis proteins (VEGF-C, apelin) and atrial natriuretic factor, which are commonly affected in cardiomyopathies. These results identify for the first time a mechanism whereby lamin A/C mutation results in enhanced expression of MAP kinases, which could be a cornerstone in the development of cardiomyopathy in Emery-Dreifuss muscular dystrophy and related myopathies caused by LMNA mutations.

44

### Loss of the Dystonia-associated Protein TorsinA Selectively Disrupts the Neuronal Nuclear Envelope

R. E. Goodchild,[1] W. T. Dauer[2]; [1]Neurology, Columbia University, NYC, NY, [2]Neurology and Pharmacology, Columbia University, NYC, NY

A glutamic acid deletion (ΔE) in the ubiquitously expressed AAA+ protein torsinA causes the neurodevelopmental disease, DYT1 dystonia. Although the majority of torsinA resides within the ER, torsinA binds a substrate in the lumen of the nuclear envelope (NE), and the ΔE mutation enhances this interaction. Using a novel cell-based screen, we identified lamina-associated polypeptide 1 (LAP1) as a torsinA-interacting protein. LAP1 is required for the NE localization of torsinA and appears to interact with torsinA through a conserved luminal domain. In order to examine whether the NE function of torsinA is involved in the pathogenesis of DYT1 dystonia we developed torsinA null and ΔE 'knock-in' mice. Mice homozygous for the null or the ΔE mutation are phenocopies and both die shortly after birth. Neurons from these mice display severely disordered nuclear membranes that contain vesicles in the perinuclear space. These abnormalities are not present in non-neuronal cells. The presence and severity of nuclear membrane abnormalities shows a developmental dependence; they initially appear in post-migratory neurons and worsen concurrent with neuronal maturation. These observations imply that the neural specificity of DYT1 dystonia derives from a unique requirement of the neuronal nuclear envelope for torsinA function.

45

### Accumulation of S cerevisiae Esc1p causes Laminopathy-like Alterations of the Nuclear Envelope that are not Inherited by Daughter Nuclei

T. Hattier, E. Andrulis, A. M. Tartakoff; Pathology, Cell Biology Program and Molecular Biology, Case Western Reserve University, Cleveland, OH

The possible existence of a lamina which determines nuclear shape in yeast is controversial since lamin sequence homologs do not exist. Nevertheless, like lamins, S. cerevisiae Esc1p has coiled-coil domains and localizes to the nuclear periphery where it anchors heterochromatin. We observe that increased expression of Esc1p causes dramatic elaborations of the nuclear envelope (NE), which extend into the cytoplasm and are reminiscent of modifications of nuclear shape seen in human laminopathies. These double membrane extensions, here referred to as ESCapades, include nuclear pores, but only limited amounts of nucleoplasm. They often contact both the nucleolus and the vacuole. Time-lapse imaging shows that ESCapades normally originate at the nucleus-vacuole junction and often wrap around the vacuole. Strikingly, examination of cells in anaphase shows that ESCapades are not inherited by daughter nuclei. Contrary to expectation, exclusion of these structures from daughters is independent of septin function and the presence of vacuoles. Moreover, they are excluded even when nuclear division is restricted to the maternal cytoplasm. Thus, this behavior may reflect the existence of an intrinsically distinct "maternal domain" of the nuclear periphery. The exclusion of atypical structures provides a striking example of "phenotypic normalization" which may sustain continued cell growth when parental nuclei have acquired potentially deleterious characteristics. Consistent with this, retention of ESCapades significantly slows the pace of bud formation in mothers while the overall speed of growth is only modestly affected. Maternal retention of atypical NE structures may be unique to the closed mitoses of budding and fission yeast; higher eukaryotic cells appear able to cope with such issues by extensive disassembly and reassembly of the nuclear envelope during mitosis

## Regulation of the Cell Cycle (46-51)

46

### CaMKII Triggers Exit from Meiosis II by Sensitising the APC/C Inhibitor XErp1 for Degradation

N. Rauh, A. Schmidt, J. Bormann, E. A. Nigg, T. U. Mayer; Cell Biology, MPI of Biochemistry, Martinsried, Germany

Vertebrate eggs awaiting fertilisation are arrested at metaphase of meiosis II by a biochemical activity termed cytostatic factor (CSF). This activity inhibits the anaphase-promoting complex/cyclosome (APC/C), an ubiquitin-ligase that triggers anaphase onset and mitotic/meiotic exit by targeting securin and M-phase cyclins for destruction. Upon fertilisation a transient rise in free intracellular calcium causes release from CSF arrest and thus APC/C activation. While it is well established that CaMKII is the essential target of the calcium signal upon fertilisation, the relevant substrates of this kinase have not been identified and the mechanism(s) leading to APC/C activation have long remained obscure. Recently, we have identified XErp1 (Emi2), a novel component of CSF activity that is both necessary and sufficient to keep the APC/C inactive in CSF-arrested *Xenopus* egg extracts. Here we show that calcium-activated CaMKII triggers exit from meiosis II by sensitising the APC/C inhibitor XErp1 for Polo-like kinase

1 (Plx1)-dependent degradation. Phosphorylation of XErp1 by CaMKII leads to the recruitment of Plx1 which in turn triggers the destruction of XErp1 by phosphorylating a site known to serve as a phosphorylation-dependent degradation signal for the ubiquitin ligase $SCF^{\beta\text{-}TRCP}$. Our findings thus explain how a calcium signal prompts the exit from meiosis through the spatiotemporal integration of the action of two key kinases, CaMKII and Plx1, both converging onto XErp1, a critical inhibitor of APC/C.

47

**Bypassing the Positive-Feedback Loops in Cdc2 Activation Uncouples the Biochemical Oscillator from Mitotic Progression**

J. R. Pomerening, E. Petschnigg, J. E. Ferrell; Molecular Pharmacology, Stanford University School of Medicine, Stanford, CA

Enzymatic control of the mitotic cell cycle ensures discrete phases of DNA replication, growth, and division. Progression into and exit from mitosis is regulated by oscillations in the activity of Cdc2-cyclin B kinase. The negative-feedback loop of this oscillator is driven by the anaphase-promoting complex (APC), which inactivates Cdc2 via cyclin B proteolysis, and controls the metaphase to anaphase transition, as well as mitotic exit. The upstrokes of Cdc2-cyclin B activity are powered by positive-feedback loops, and while positive feedback is known to elicit useful behaviors such as ultrasensitivity and bistability from cell-signaling modules, the biological importance of these characters in defining the systems-level behavior of the Cdc2/APC oscillator is not well understood. By applying a positive-feedback-insensitive mutant of human Cdc2 (Cdc2T14AY15F), Cdc2AF, we short-circuited the normal pathway of Cdc2 activation in HeLa cells. By using multiple cell cycle biosensors and live-cell imaging, we discovered that bypassing the positive-feedback loops involved in Cdc2 activation uncouples the biochemical oscillations in Cdc2 activity from the physiological events that must occur during mitosis. A lamin A-YFP biosensor revealed that nuclear envelope breakdown and nuclear envelope reformation events without cytokinesis could occur multiple times within the same Cdc2AF-transfected cell. A cyclin B1-YFP biosensor revealed that wild-type Cdc2-transfected cells would undergo one round of cyclin stability/proteolysis and division during a 12-hour period, whereas cells transfected with Cdc2AF would undergo multiple periods of cyclin stability/instability - up to six - within the same, non-dividing cells during a 12-hour period. Finally, using kinase-activity assays and multivariate flow cytometry, we confirmed that short-circuiting these positive-feedback loops causes somatic cells to undergo repetitive biochemical pseudo-cycles without being able to actually initiate and progress through mitosis.

48

**Aurora-A Kinase is Required for Timely Nuclear Envelope Breakdown in C elegans**

N. C. Portier, P. Maddox, K. Oegema; Ludwig Inst. for Cancer Research, La Jolla, CA

Aurora-A is a mitotic serine/threonine kinase that localizes to centrosomes, the major microtubule organizing centers in animal cells. The gene encoding Aurora-A is amplified in many cancers, possibly because overexpression overrides critical checkpoints, promoting genetic instability. It has been proposed that centrosomes influence cell cycle progression by focusing cell cycle regulators. Consistent with this idea, Aurora-A has been shown to regulate both the recruitment of pericentriolar material during mitotic entry (centrosome maturation), and G2/M progression. We used the C. elegans early embryo to investigate the relationship between the role of Aurora-A in centrosome maturation and cell cycle progression. Upon fertilization, the oocyte-derived nucleus undergoes two meiotic divisions. The resulting haploid pronuclei replicate their DNA, the chromatin condenses, and the nuclear envelopes break down (NEBD). We imaged embryos expressing fluorescently-tagged histones to visualize chromosomes and thus determine cell cycle milestones. We found that depletion of Aurora-A by RNA-mediated interference extends the time interval between anaphase of meiosis II and NEBD in mitosis. By using a quantitative light-microscopy-based live assay to measure chromosome condensation we showed that depletion of aurora-A increases the interval between the onset of chromosome condensation and NEBD. However, the rate of chromosome condensation is unaffected in depleted embryos. This result suggests that the timing of mitotic entry is not affected by Aurora-A depletion, but that NEBD is specifically delayed. Disruption of microtubule-nuclear envelope interactions by nocodazole treatment or dynein depletion did not affect the timing of NEBD, indicating that centrosomes have a role in NEBD that is independent of microtubules. Depletion of other proteins required for centrosome assembly delays NEBD, but to a lesser extent than depletion of Aurora-A. This suggests a centrosome-independent contribution of Aurora-A to NEBD.

49

**Mto1p and Mto2p Regulate the Function of the Fission Yeast γ-TuC at the MTOCs**

S. Venkatram, K. L. Gould; Cell and Developmental Biology, Vanderbilt University Medical School, Nashville, TN

Microtubules (MTs) in fission yeast are organized by three different microtubule-organizing centers (MTOC): the interphase MTOCs (iMTOC) that organize cytoplasmic microtubules, the spindle pole bodies (SPBs) that organize the mitotic spindle and astral MTs and the equatorial MTOC (eMTOC) that organizes the post-anaphase array of MTs. Using proteomic approaches, we identified Mto1p and Mto2p, which associate with the gamma-tubulin complex (γ-TuC), and are important for proper organization of all cytoplasmic MTs. Consistent with its role in MT organization, *mto1*Δ cells exhibit defects in cell polarity, nuclear positioning, astral MT formation and cleavage plane specification. In addition, we have shown that the eMTOC is critical for proper anchoring of the cytokinetic actin ring during cytokinesis. How does the g-TuC, specifically Mto1p and Mto2p perform these functions? In this study, we have identified Myp2p, a non-essential myosin II component of the actin ring, as a possible link between the ring and the eMTOC and hence perform a role in ring anchoring by the eMTOC. Moreover, structure/function analyses of Mto1p and Mto2p have revealed that distinct domains of these proteins target them to the different MTOCs and contribute to different aspects of their function in association with the γ-TuC. Significantly, we have found that Mto1p is a microtubule-binding protein suggesting that Mto1p links the γ-TuC to cytoplasmic MTs. Also, both Mto1p and Mto2p are phosphoproteins and their phosphorylation status is regulated with respect to the cell cycle. The role of this phosphorylation in Mto2p function will also be presented. Taken together, our studies suggest a model in which distinct domains of Mto1p and Mto2p contribute to their function in organizing different MT structures and help anchor the cytokinetic actin ring through interaction with conserved ring components.

50

**Cellprofiler: Free Software for Automatically Measuring Cells in Images**

C. M. Clarke,[1] A. E. Carpenter,[2] T. R. Jones,[1] D. B. Wheeler,[2] O. Friman,[3] J. Chang,[2] D. A. Guertin,[2] I. Kang,[1] P. Golland,[1] D. M. Sabaini[2]; [1]MIT,

Cambridge, MA, [2]Whitehead, Cambridge, MA, [3]Harvard, Cambridge, MA
Advances in imaging hardware now allow the rapid collection of thousands of high resolution images of cells. Automatically measuring features of cells quantitatively from these images has been difficult due to the limitations and often proprietary nature of available image analysis software. We have therefore developed CellProfiler cell image analysis software to allow biologists without training in computer vision or programming to quantitatively measure cells in thousands of images automatically, without tedious user interacion. This freely available, open-source software project is modular, allowing simple adaptation to a variety of cell types and phenotypes. CellProfiler is compatible with common image formats (bmp, cur, dib, fts, fits, gif, hdf, ico, jpg, jpeg, pbm, pcx, pgm, png, pnm, ppm, ras, tif, tiff, xwd) and movie formats (avi, stk). Here we describe and validate the software using cells from human, mouse, yeast, and fruit fly to measure phenotypes including cell count, cell size, cell cycle distribution, and the levels and localization of proteins and phospho-proteins, including application to time-lapse and high-throughput experiments.

51

**Requirement For Cdk4 Kinase Function In Breast Cancer**

P. Sicinski; Harvard Medical School, Boston, MA
Cyclin D1 protein is overexpressed in the majority of human breast cancers. We previously found that mice lacking cyclin D1 are resistant to mammary carcinomas trigged by ErbB-2 oncogene. In the current study we investigated which function of cyclin D1 is required for ErbB-2-driven mammary oncogenesis. We report that the ability of cyclin D1 to activate cyclin-dependent kinase CDK4 underlies the critical role for cyclin D1 in breast cancer formation. We also found that the continued presence of CDK4-associated kinase activity is critically required for breast tumorigenesis. We analyzed primary human breast cancers and found high cyclin D1 levels in a subset (approx. 25%) of tumors with ErbB-2 amplification. These D1-high, ErbB-2-overexpressing breast cancers have particularly poor prognosis. We propose that this subset of breast cancer patients might benefit from inhibiting CDK4 kinase activity.

## Signaling in the Immune System (52-57)

52

**T Cell Receptor Nanoclusters Sustain Signaling in the Immunological Synapse**

M. L. Dustin, R. Varma, G. Campi, T. N. Sims; Pathology, NYU SOM, New York, NY
Dynamic TCR-MHC-peptide (MHCp) interactions sustain T cell signaling. The site of these dynamic events in the stable immunological synapses is unknown. We have utilized primary T cells from T cell receptor (TCR) transgenic mice interacting with supported planar bilayers containing MHCp and ICAM-1. The interface between the T cell and planar bilayers is defined as the synapse. We have found that TCR-MHCp engagement occurs continuously in the periphery of the synapse leading to clustering, phosphorylation and translocation of the TCRs towards the center where TCR-MHCp interactions accumulate. Perturbations that stop TCR signaling, such as anti-MHCp antibodies or disruption of actin cytoskeleton, also stop formation and translocation of TCR nanoclusters, but have no immediate impact on the central TCR macrocluster. The non-receptor tyrosine kinase ZAP-70 is recruited to the TCR nanoclusters, which are also sites of tyrosine phosphorylation. Thus, TCR engagement required for signaling is continuously renewed in the periphery of the immunological synapse. We suggest the immunological synapse has at least three distinct signaling zones, a peripheral lamellipodium where signaling is initiated, an intermediate lamella where signaling is amplified and sustained and a central zone where microclusters converge and tyrosine kinase signaling is extinguished.

53

**Single Molecule Imaging of Immunological Synapse Formation in Planar Bilayer-Stimulated T Cells**

A. D. Douglass, R. D. Vale; HHMI and Department of Cell and Molecular Pharmacology, UC San Francisco, San Francisco, CA
We have developed a method of stimulating immortalized, Jurkat T cells with supported lipid bilayers that contain adhesion molecules (CD58 or ICAM-1) as well as antibodies directed against the T cell receptor (TCR). In addition, we can follow the dynamic behavior of other signaling and adhesion proteins with GFP tags. The anti-TCR antibodies cause the TCR to coalesce into microclusters at the cell periphery, and these microclusters are then transported to the center of the contact by retrograde actin flow. The central region of TCR accumulation (termed the “cSMAC”) is surrounded by a ring of LFA-1 (the “pSMAC”), an arrangement that is reminiscent of the immunological synapse that forms at the interface between a T cell and an antigen-presenting cell. Surprisingly, several proteins involved in transducing signals from the TCR, such as the adaptor protein, LAT, and the kinase, Lck, preferentially localize to regions of the cell-bilayer interface that are enriched in the coreceptor CD2, rather than to TCR-rich clusters. Through single molecule imaging by total internal reflection fluorescence (TIRF), we are in the process of creating a “diffusion map” of the Jurkat immunological synapse. Our preliminary work shows boundaries between the lamella, pSMAC and cSMAC that often appear to constitute diffusion barriers that limit the movement of proteins between compartments. Thus, our work shows that Jurkat cells will spatially organize molecules in a manner than resembles the immunological synapse of native T cells. We also show the rapid formation of signaling microclusters in the lamella, the actin-based transport of these clusters towards the cell center to generate the cSMAC, and we provide the first detailed analysis of diffusion dynamics within the immunological synapse.

54

**Automated Real-Time Image Cross-Correlation Analysis of Mast Cell Signaling Reveals Detailed Dynamics of Early Signaling Events**

R. Das, D. Holowka, B. Baird; Chemistry and Chemical Biology, Cornell University, Ithaca, NY
Signaling in mast cells and basophils is mediated through IgE and its high affinity cell surface receptor Fc-epsilon-RI. Crosslinking of the receptors by a cognate multivalent antigen initiates a signal cascade leading to degranulation and release of mediators of the allergic immune response. We probe the spatio-temporal dynamics of fluorescent chimeras of signaling proteins involved in the early steps of this signal cascade using real-time multicolor confocal fluorescence microscopy. We image living RBL-2H3 mast cells at physiologically relevant temperatures following stimulation with multivalent antigen and acquire sequential images with a 3s time resolution. A fluorescent tag on the antigen allows us to visualize the plasma membrane localization of crosslinked receptors. We have developed an automated image analysis scheme that allows us to rapidly quantify the recruitment of fluorescent intracellular proteins to the plasma membrane and their colocalization with crosslinked receptors as measured by a cross

correlation between the plasma membrane distribution of the two fluorophores. We systematically apply this analysis to characterize stimulated interactions of several chimeric proteins, including the tyrosine kinases Lyn and Syk, and the adaptor protein LAT. Using an Akt PH domain chimera, we find evidence for a time-dependent increase in localized phosphatidylinositol-(3,4,5)-trisphosphate ($PIP_3$) production at sites of receptor aggregation.

55

**High Affinity LFA-1 is Recruited to The Leading Edge During T Cell Migration and Immunological Synapse Formation**

N. A. Morin,[1] M. Shimaoka,[2] T. A. Springer,[2] J. W. Janowski,[1] J. S. Reichner,[1] M. Kim[1]; [1]Surgery, Rhode Island Hospital, Brown Medical School, Providence, RI, [2]The CBR Institute for Biomedical Research, Inc., Boston, MA

Cell migration is central to many biological and pathological processes, including embryogenesis, tissue repair and regeneration as well as cancer and the inflammatory response. Leukocyte migration from blood into lymphoid tissues or sites of inflammation occurs through interactions of cell surface integrins with their ligands expressed on the vascular endothelium and the extracellular matrix. Integrin LFA-1 (αLβ2) is a critical component in the effective trafficking of leukocytes. We hypothesize that only a small subpopulation of LFA-1 on the surface of T cells is activated by chemokine stimulation and the high affinity LFA-1 is localized at the leading edge of the polarized cells in a spatially restricted manner during migration. Quantitative analysis of LFA-1 activation with activation specific monoclonal antibodies showed only a small population of total LFA-1 on human T cell is activated by stimulation with SDF-1. Confocal microscopy and 3D reconstruction images of LFA-1 immunofluororescence staining with conformation specific (active vs inactive) monoclonal antibodies revealed the distinct three-dimensional distribution of the active conformations of LFA-1 at the leading edge of T cells engaged in migration and the cell-cell interface during immunological synapse formation. Selective inhibition of the active form of LFA-1 was sufficient to block T cell transendothelial migration. Dynamic fluorescence resonance energy transfer (FRET) measurements of Rap-1 CFP/YFP FRET sensor on live migrating primary T cell showed the distribution of Rap-1 activation is mainly localized near the nucleus and periodic strong Rap-1 activation spread toward the membrane protrusion. These data suggest that only a small subpopulation of LFA-1 at the leading edge of polarized T cells is functionally activated and competent to mediate migration and immunological synapse formation.

56

**The Alpha4 Integrin-Paxillin Interaction in Lymphocyte Trafficking during Development and Inflammation**

D. M. Rose,[1] C. C. Feral,[2] A. D. Sydlaske,[1] P. Scott,[1] M. H. Ginsberg[2]; [1]Medicine, VA Medical Center/UCSD, San Diego, CA, [2]Medicine, UCSD, San Diego, CA

VLA-4 integrins (α4β1) function in lymphocyte trafficking through compartments of the immune system during immune surveillance and inflammation. We have previously described the direct physical interaction of the α4 integrin cytoplasmic domain with the signaling adapter molecule, paxillin, and defined the importance of this interaction in lymphocyte migration in vitro. To determine the role of the α4-paxillin interaction in lymphocyte trafficking during the development of the immune system and inflammation, a novel mouse strain was generated with a selective mutation (Y991A) introduced into the α4 gene that disrupts paxillin binding to the α4 cytoplasmic domain. Mice homozygous for the mutation were viable with no gross abnormalities in development. The α4Y991A mice had no defect in hematopoiesis as judged by abundance of different cell populations in the blood. Furthermore, the architecture and lymphocyte subpopulations in primary and secondary lymphoid tissues of α4Y991A mice were similar to α4WT mice. However, upon challenge, α4Y991A mice had a significant defect in lymphocyte recruitment during thioglycollate-induced peritonitis. This was selective for lymphocytes as no difference was observed in neutrophil recruitment to the peritonea between α4Y991A and α4WT mice. To further study lymphocyte trafficking during inflammatory and non-inflammatory conditions, splenocytes were isolated from α4WT and α4Y991A mice and differentially labeled. Mixed cell populations were introduced back into α4WT mice by tail vein injection, and trafficking of labeled splenocytes to spleens and peritonea of thioglycollate-treated mice was followed by flow cytometry. While α4WT and α4Y991A cells migrated equally well to the spleen, there was a marked reduction in migration of α4Y991A splenocytes to the inflamed peritoneum. These results indicate that the α4-paxillin interaction plays a selective role in lymphocyte trafficking to sites of inflammation, but not in trafficking during development and homeostasis.

**The Differential Roles of Ezrin and Moesin in Immune Synapse Formation**

T. Ilani, A. Bretscher; MB&G, Cornell University, Ithaca, NY

The immune synapse (IS) is the specialized junction between T-cell and antigen presenting cell (APC) characterized by clustering of T-cell receptors and their associated proteins. IS forms within seconds following T cell-APC recognition and persists for hours. The cytoskeleton plays a major role in this molecular reorganization, so an understanding of the regulated attachment of membrane proteins to the cytoskeleton lies at the heart of IS formation. The ERM (Ezrin/Radixin/Moesin) proteins, which provide a regulated linkage between membrane proteins and the actin cytoskeleton, have been implicated in T-cell activation and IS formation. The activity of ERM proteins is regulated by reversible phosphorylation at a conserved residue, which opens the molecule allowing its linking functions. The existence of three ERM members is frequently referred to as redundancy. Nonetheless, using confocal microscopy and biochemical methods we found that in both a T-cell line and freshly isolated human T-cells ezrin and moesin are differentially distributed. In resting T-cells moesin is restricted to the cell membrane and is in its active phosphorylated form, whereas ezrin shows a cytoplasmic distribution and is in its dormant non-phosphorylated form. Following T-cell receptor activation ezrin relocalizes to the membrane where it is subsequently phosphorylated while moesin stays localized at the membrane and shows a rapid and transient dephosphorylation. We further analyzed the time course of spatial changes and activity regulation of ERM during IS formation. Upon T-cell receptor engagement ezrin is localized at the activation site along with CD3 and PKC-θ whereas moesin is rapidly dephosphorylated and removed from the activation sitetogether with CD43. These distinctions are consistent throughout synapse maturation and point to a differential role for these proteins in IS formation.

### SnRNPs: Cellular and Viral Regulators of Gene Expression

J. A. Steitz; Dept MBB/HHMI, Yale University, New Haven, CT

Small nuclear RNAs (snRNAs), the most famous of which function in the removal of introns from pre-mRNAs, are important contributors to gene expression. The discovery of snRNAs complexed with proteins to form small nuclear ribonucleoproteins (snRNPs) will first be reviewed. A second class of snRNPs guides the introduction of nucleotide modifications such as pseudouridine and 2'-O-methyl groups into other RNAs. Insight into the function of pseudouridine modifications has recently come from an unexpected source - study of the U7 snRNP, which directs the 3'-end maturation of metazoan histone mRNAs. Nucleotide analog interference mapping (NAIM) and conventional mutagenesis reveal that the ability of a particular sugar moiety within the Sm site to assume the 2'-endo conformation is essential for U7 snRNP assembly. Pseudouridine interferes with Sm protein binding by rigidifying the backbone in the 3'-endo conformation. This argues that conserved pseudouridine modifications in rRNA and snRNAs are introduced where it is functionally critical to fix the backbone in the 3'-endo conformation. Viruses often provide powerful tools to dissect gene regulation. Kaposi's sarcoma-associated herpesvirus (KSHV) produces a 1 kb non-coding, polyadenylated, nuclear RNA called PAN in lytically infected human cells. PAN contains a novel post-transcriptional element, the PAN-ENE (PAN expression and nuclear retention element), essential for its high levels of accumulation. Insertion of the PAN-ENE is also sufficient to significantly increase RNA expression from an otherwise inefficiently expressed intronless b-globin construct, but does not concomitantly enhance the production of encoded protein; rather, the unspliced b-globin mRNA is retained in the nucleus. The nuclear retention activity of the PAN-ENE can be overcome by tethering export factors or by inserting an intron into the mRNA. Recent advances provide insights into the mechanism of action of the PAN-ENE in regulating the levels of nuclear RNAs.

## Growth Factors & Receptors (59-82)

### Control of EGF Receptor Endocytosis by Receptor Dimerization, Rather Than Receptor Kinase Activation

Q. Wang,[1] G. Villeneuve,[2] Z. Wang[1]; [1]Department of Cell Biology, University of Alberta, Edmonton, AB, Canada, [2]University of Alberta, Edmonton, AB, Canada

Given that ligand binding is essential for the rapid internalization of epidermal growth factor (EGF) receptor (EGFR), the events induced by the ligand binding likely contribute to the regulation of EGFR internalization. These events include receptor dimerization, activation of intrinsic tyrosine kinase activity and autophosphorylation. While the initial results are very controversial regarding the role of EGFR kinase activity in EGFR internalization, more recent data suggest that EGFR kinase activation is essential for EGFR internalization. However, we showed here that inhibition of EGFR kinase activation by mutation or chemical inhibitors did not block EGF-induced EGFR internalization. Instead, EGFR dimerization is necessary and sufficient to stimulate EGFR internalization. We conclude that EGFR internalization is controlled by EGFR dimerization, rather than EGFR kinase activation. Our results also define a new role for EGFR dimerization: EGFR dimerization by itself can drive EGFR internalization, independent of its role in the activation of EGFR kinase.

60

### Receptor Downregulation Confers Response Robustness upon the EGFR System

H. Shankaran, H. S. Wiley, H. Resat; Pacific Northwest National Laboratory, Richland, WA

OBJECTIVE: The epidermal growth factor receptor (EGFR) plays a critical role in proliferation and differentiation. An important feature of EGFR signaling is that receptor internalization is enhanced when EGFR binds its ligand EGF. This property termed downregulation is viewed as a mechanism for signal termination. Here, we employ mathematical modeling to explore the role of downregulation in controlling the input-output characteristics of this signaling system. METHODS: We constructed a mathematical model that includes EGF-EGFR binding, EGFR synthesis and internalization. We quantified the extent of downregulation $\delta$ as the ratio of the internalization rate of receptor-ligand complexes to that of free receptors. We ran the model to determine the evolution of surface receptor-ligand complexes (system output) in response to time-varying sinusoidal ligand profiles (system input) over a range of $\delta$ values. RESULTS: The response delay is the time-difference between the peaks of the output and input profiles, and can be used as a performance measure. For $\delta$ >10, the system output matches the input remarkably well with a delay of ~10 min irrespective of the input wavelength, $\lambda$ in the range $\lambda$=100-1000 min. The EGF-EGFR system has a $\delta$ of ~20-30, and falls in this robust region of the parameter space. Reducing $\delta$ increases response delay in addition to making it a function of the input wavelength. For the case of no downregulation ($\delta$=1), the delay varies from 25 min for $\lambda$=100 min to 110 min for $\lambda$=1000 min. CONCLUSIONS: Downregulation enables the EGF-EGFR system to generate outputs that robustly reproduce the input profile over a wide-range of wavelengths. We believe that investigating elements of biochemical networks in this fashion to elucidate their role in controlling input-output characteristics will prove to be invaluable in constructing and understanding complex whole cell models.

61

### PKA, but not Epac, Increases the Ligand-dependent Activation of ErbB/HER Receptors and Proliferation of Cultured Schwann Cells

P. V. Monje, M. Bartlett Bunge, P. M. Wood; University of Miami School of Medicine, Miami Project to Cure Paralysis, Miami, FL

The elevation of intracellular cAMP synergistically enhances the heregulin-dependent proliferation of cultured Schwann cells (SCs); however, the mechanism by which this occurs has not been completely defined. To better understand this mechanism, we studied the effect of pharmacological inhibitors of protein kinase A (PKA) and cell permeable cAMP analogs with demonstrated specificity for activation of PKA, or Epac (exchange protein activated by cAMP), on heregulin-induced proliferation. We observed that activation of PKA, but not Epac, synergistically increased heregulin-dependent proliferation of both adult human and rat SCs. We further observed that cAMP signaling through PKA synergistically increased the ligand-dependent activation of the neuregulin receptors ErbB2/3 (HER2/3) and downstream signaling in the mitogen-activated protein kinase (MAPK) and the phosphatidyl-inositol-3-kinase (PI3-K)-Akt pathways. The activation of PKA by forskolin or by cAMP analogs did

not result in receptor phosphorylation when administered in the absence of heregulin. Consistent with these observations, physiological changes in cAMP promoted by the stimulation of several G-protein coupled receptors, including adenosine and adrenaline receptors, synergistically enhanced ErbB/HER phosphorylation and SC proliferation in response to heregulin. Overall, our results suggest a novel mechanism in which agents that elevate cAMP increase the ligand-induced activation of heregulin receptors by a PKA-dependent pathway and thereby increase cell cycle progression in SCs.

62

**Caveolin-1 Phosphorylation Under Oxidative Stress is Required for Caveolae-mediated Perinuclear Trafficking of the EGF Receptor**

E. M. Khan, J. M. Heidinger, M. Levy, T. Ravid, T. Goldkorn; Internal Medicine - Pulmonary, University of California, Davis, Davis, CA

The epidermal growth factor (EGF) receptor (EGFR) is over-expressed in several types of cancer cells and the regulation of its oncogenic potential has been widely studied. The inability of the EGFR to be down-regulated via clathrin-mediated endocytosis and degradation has been linked to its oncogenicity. The paradigm for EGFR down-regulation involves the trafficking of activated receptor molecules from the plasma membrane, through clathrin-coated pits, and into the cell for lysosomal degradation. We have previously shown that oxidative stress generated by $H_2O_2$ results in aberrant phosphorylation of the EGFR. This results in the loss of c-Cbl-mediated ubiquitination of the EGFR and, consequently, prevents its degradation. However, we have found that c-Cbl-mediated ubiquitination is required solely for degradation but not for internalization of EGFR under oxidative stress. To further examine the fate of the EGFR under oxidative stress, we used confocal analysis to show that the receptor not only remains co-localized with caveolin-1 at the plasma membrane, but at longer time points, is also sorted to a perinuclear compartment via a clathrin-independent, caveolae-mediated pathway. Our findings indicate that although EGFR associates with caveolin-1 constitutively, caveolin-1 is hyper-phosphorylated only under oxidative stress, which is essential in transporting EGFR to a perinuclear location, where it is not degraded and remains active. Hence, oxidative stress may have a role in tumorigenesis by not only activating the EGFR, but also by promoting prolonged activation of the receptor both at the plasma membrane and within the cell.

63

**The Leucine-Rich Repeat Protein LRIG1 Inhibits ErbB Mediated Breast Tumor Cell Growth**

J. K. Miller, D. L. Shattuck, M. B. Laederich, K. L. Carraway III, C. A. Sweeney; Biochemistry and Molecular Biology, University of California, Davis, Sacramento, CA

Receptor tyrosine kinases (RTKs) are key mediators of normal cellular processes such as the development and maintenance of tissues, and are also critically involved in the growth and progression of human cancers. One subfamily of RTKs is the epidermal growth factor (EGF) family which consists of four members: EGF receptor (EGFR), ErbB2, ErbB3, and ErbB4. Binding of EGF-like growth factors induces a global signaling cascade that affects varied downstream processes including proliferation, motility, and survival. Aberrant activation of this family of receptors is strongly linked to the generation and progression of breast cancer. While small molecule inhibitors and monoclonal antibodies have had some therapeutic success, endogenous proteins may also be exploited to downregulate receptor levels in tumor cells. Specifically, the leucine-rich repeat protein, LRIG1, has been previously shown by our lab to negatively regulate all four members of the ErbB family, and LRIG1-mediated receptor ubiquitination and degradation may contribute to the suppression of ErbB receptor function. Here we seek to determine whether LRIG1 can regulate endogenous receptors in cultured breast tumor cell lines. Through the use of viral mediated transduction, we have found that endogenous ErbB receptors are reduced following transduction with LRIG1. In addition, these transduced cell lines display a concomitant decrease in signaling and, ultimately, proliferation in response to EGF-like growth factors. These data suggest that increasing levels of LRIG1 can counteract aberrant ErbB signaling and decrease proliferation in breast lines responsive to EGF-like growth factors. Furthermore, the LRIG1 protein could hold either therapeutic or prognostic value for breast cancer treatments.

64

**Regulated Shedding of EGFR Ligands is Controlled by Oligomerization**

G. J. Newton, L. K. Opresko, D. J. Panther, G. Orr, R. D. Quesenberry, H. S. Wiley; Biological Sciences, Pacific Northwest National Laboratory, Richland, WA

The epidermal growth factor receptor (EGFR) can be activated by seven ligands that are initially synthesized as membrane-bound precursors. We have found that these ligands can be classified as being either slowly or rapidly released, based on their shedding rates measured using quantitative assays. To investigate the structural basis for these differences, we constructed chimeras of TGFα (high release) and HB-EGF (low release) in which we swapped the stem, transmembrane (TM), and cytoplasmic domains between the two ligands. After expressing the chimeric ligands in Chinese hamster ovary cells, we measured the ligand release rate relative to the total level of expressed ligand (fractional release). We found that replacing either the stem or TM domain of HB-EGF with those from TGFα significantly increased its rate of release, suggesting that some structural aspect of the ligand inhibited shedding. To test our hypothesis that these regions are involved in ligand oligomerization, we used site-directed mutagenesis to change three charged polar residues in the stem and three uncharged polar residues in the TM domain to either alanine or valine. We observed a significant increase in shedding following mutations in either the stem or TM domains, but double mutations displayed shedding rates similar to TGFα. We used fluorescent resonance energy transfer (FRET) to directly demonstrate oligomerization of the chimeras and observed an inverse relationship between the degree of FRET and the fractional release of the ligands. In the double mutant that was rapidly shed, there was no detectable FRET, indicating that these ligands do not form oligomers. Taken together, our results suggest that EGFR ligands can form oligomers mediated by intermolecular interactions within both the stem and TM domains. In turn, the degree of ligand oligomerization can control the regulated shedding rate.

65

**The Carboxy-terminal Domain of HB-EGF Regulates Bcl6, a Transcriptional Repressor, via Direct Interaction**

Y. Kinugasa, M. Hieda, S. Higashiyama; School of Medicine, Ehime University, Ehime, Japan

Heparin-binding EGF-like growth factor, a member of the EGF family is synthesized as a type I transmenbrane precursor (proHB-EGF) containing of the extracellular EGF-like domain and a cytoplasmic tail. Proteolytic cleavage of extracellular domain yields the soluble EGF-like growth factor

(sHB-EGF) and the transmembrane-cytoplasmic fragment (HB-EGF-TMC). Recently we demonstrated that transmembrane remnant, HB-EGF-TMC, translocates from the plasma membrane to the nucleus. Its nuclear translocation triggered nuclear export of a transcriptional repressor, PLZF and then the transcriptional suppression by PLZF is abolished. To establish the general nature of the transcriptional regulation by HB-EGF-TMC, we attempted to find out other transcriptional repressors regulated by HB-EGF-TMC. PLZF contains an amino-terminal BTB domain and carboxyl-terminal Krüppel-type zinc finger motifs, which is essential for the complex formation with HB-EGF-TMC. We screened transcriptional repressors having BTB domain and zinc finger motifs and found that a transcriptional repressor, B cell lymphoma 6 (Bcl6) interacts with HB-EGF-TMC. Transient transfection and co-precipitation experiment showed the interaction between Bcl6 and HB-EGF-TMC in vivo. Recombinant Bcl6 directly bound to cytoplasmic domain of HB-EGF via its zinc finger motifs in AlphaScreen assay. Bcl6 represses the cyclinD2 gene transcription. HB-EGF-TMC signaling abolished the transcriptional repression by Bcl6 in luciferase reporter assay. Moreover HB-EGF-TMC signaling activated the cyclinD2 protein expression in several lines of cultured cells. These findings show a novel transcriptional regulation; after releasing EGF-like growth factor, HB-EGF-TMC translocates to the nucleus and activates the transcription. As a result proHB-EGF is bidirectional signaling molecules, soluble EGF-like growth factor activates receptor tyrosine kinase in one direction and membrane-tethered fragment, HB-EGF-TMC regulates transcription in the other direction. We will also discuss the detailed localization of HB-EGF-TMC in the nucleus and its role in the transcriptional regulation

66

**P2Y1 Nucleotide-Receptors Increase Cell Proliferation Trans-Activating the EGF Receptor**

S. Buvinic, M. Bravo-Zehnder, J. Huidobro-Toro, A. González; Depto. Reumatología, Fac. Medicina, and Centro de Regulación Celular y Patología, Fac. Ciencias Biológicas. P. Universidad Católica de Chile, and MIFAB, Santiago, Chile

Metabotropic P2Y1 receptors (P2Y1R) are activated by extracellular nucleotides and regulate a variety of physiological events. Most studies on P2Y1R focused their role in rapid processes that depend on a rise in intracellular calcium, remaining unknown whether they exert long-term effects. Several G protein-coupled receptors (GPCR) modulate cell proliferation trans-activating the epidermal growth factor receptor (EGFR). Nucleotides are continuously released from cells and therefore they might act as local trophic factors. We found that epithelial FRT cells and HeLa cells responded to the selective P2Y1R agonist 2-MeSADP by increasing [H3]-thymidine incorporation with EC50 values of 42 ± 7 and 76 ± 3 nM, respectively; MRS 2179, a P2Y1R antagonist, abolished this effect. Interestingly, 2-MeSADP also increased the tyrosine phosphorylation of EGFR, by 3-4 fold in FRT cells and 60 fold in HeLa cells, leading to ERK1/2 activation. Inhibitors of EGFR kinase (AG1478), PKC (Ro318220) and metalloproteases (Ilomastat) reduced proliferation induced by 2-MeSADP. Strikingly, degradation of endogenously released nucleotides with apyrase reduced by 15-25% the basal proliferation rate of FRT and HeLa cells. Furthermore, epithelial MDCK cells overexpressing P2Y1R increased their proliferation rate through a mechanism that depended on EGFR activation. These results revealed that P2Y1R stimulation trans-activates EGFR leading to increased proliferation of both epithelial cells and cancerous cells, thus contributing to maintain the basal proliferation rate of these cells. Because nucleotides are widely released after cell damage and tissue injury, they could also play a role in tissue repair. (Funded by FONDAP grant 13980001 and Millennium project from MIDEPLAN).

67

**Conditional Activation of FGFR1 and FGFR2 in HC11 Mouse Mammary Epithelial 3D Cultures Differentially Regulates Cell Survival and Invasion**

W. Xian, K. L. Schwertfeger, T. C. Vargo-Gogola, J. M. Rosen; Molecular and Cellular Biology, Baylor College of Medicine, Houston, TX

Fibroblast growth factors and their respective receptors (FGFR) have been implicated in mediating various aspects of mammary gland development and cancer progression. Although FGFR1 and FGFR2 share considerable amino acid sequence homology, these two receptor tyrosine kinases (RTKs) exhibit unique expression patterns and ligand binding capacities, exerting distinct effects during development and cancer progression. To date, most studies of FGFR signaling have been performed in 3T3 fibroblasts and other non-epithelial cells in two-dimensional culture systems and have not differentiated between effects of specific ligands. Thus, the unique signaling pathways and phenotypes elicited by these two highly related RTKs in polarized epitheli*a* have not been examined. Accordingly, we have developed an *in vitro* three-dimensional HC11 mouse mammary epithelial cell culture model combined with a ligand-independent, chemically-inducible FGFR dimerization system. Using this model we have observed distinct phenotypic and signaling differences following activation of iFGFR1 or iFGFR2. iFGFR1 activation resulted in high-level and sustained ERK phosphorylation, as well as differential effects on FRS2 phosphorylation as compared to iFGFR2. While activation of both RTKs in growth-arrested and polarized mammary acini led to reinitiation of cell proliferation and loss of cell polarity, only iFGFR1 activation increased cell survival. In contrast, iFGFR2 activation resulted in dramatically increased cell death even in the outer layer of cells in direct contact with the basal lamina. This appears to be a consequence of rapid tyrosine dephosphorylation of focal adhesion kinase following iFGFR2 activation. Additionally, dimerization of iFGFR1, but not iFGFR2, caused increased HC11 cell invasive properties and EMT. These results indicate that FGFR1 and FGFR2 may contribute differently to the etiology and progression of breast cancer. Supported in part by NIH grant CA16303.

68

**Endogenous FGF2 is Necessary for the Mitogenic Response to Prostaglandin F2a**

M. Sabbieti,[1] D. Agas,[1] L. Xiao,[1] L. Marchetti,[2] M. M. Hurley[1]; [1]Endocrinology and Metabolism, University of Connecticut Health Center, Farmington, CT, [2]Comparative Morphology and Biochemistry, University of Camerino, Camerino, Italy

Previous studies demonstrated that PGF2a regulated FGF2 and FGF receptor 2 mRNAs expression in Py1a osteoblastic cells and induced nuclear accumulation and co-localization of FGF2/FGFR2 by both protein kinase C and p44/42 ERK mechanisms. To study the biological relevance of PGF2a induced FGF-2/FGFR2 nuclear localization we used, as a model, primary calvarial osteoblasts from neonatal Fgf2+/+ and Fgf2-/- mice. Dose response studies showed that 24 h treatment with PGF2a (10-5 and 10-6M) significantly increased proliferation only in Fgf2+/+ osteoblasts. In contrast exogenous FGF2 18kD isoform (10-9 M) increased proliferation of both Fgf2+/+ and Fgf2-/- osteoblasts suggesting that the effect of exogenous FGF2 does not require the constitutively expressed isoforms of FGF2. To study the signal pathways, osteoblasts from Fgf2+/+ and Fgf2-/- mice were pre-treated with H89 (10-7 M), a protein kinase A inhibitor, for 1 h then treated with PGF2a or FGF2 for an additional 24h. Pre-treatment with H89 blocked the proliferative effect of FGF2 in osteoblasts of both genotype as well as the proliferative effect of PGF2a in Fgf2 +/+

osteoblasts suggesting involvement of the PKA pathway in the mitogenic response. FGF2 increased the p44/42 MAPK synthesis in Fgf2+/+ and Fgf2-/-osteoblasts, while PGF2a increased p44/42 synthesis only in Fgf2+/+ cells indicating that endogenous FGF2 was important in PGF2a activation of the MAPK pathway. Pre-treatment with PD98059 (4x10-6 M), a MEK/ERK inhibitor, blocked the mitogenic response to FGF2 in Fgf2+/+ and Fgf2-/- osteoblasts and the proliferative effect of PGF2a in Fgf2+/+ osteoblasts.This data demonstrate for the first time that the proliferative effect of PGF2a on osteoblasts is dependent on FGF2 expression. We conclude that some of the biologic responses to PGF2a in osteoblasts are dependent on FGF2 via modulation of both PKA and MAPK pathways.

69

**Organically Modified Silica Nanoparticles (ORMOSIL) as a Vector for Gene Delivery into the Brain - Mechanisms Controlling Proliferation of Neural Stem Cells**

M. K. Stachowiak,[1] D. J. Bahrali,[2] E. K. Stachowiak,[1] I. Roy,[2] I. Klejbor,[1] N. Kaur,[2] E. J. Bergey,[2] P. N. Prasad[2]; [1]Pathology and Anatomical Sciences, SUNY, Buffalo, Buffalo, NY, [2]Chemistry, SUNY, Buffalo, Buffalo, NY

The present study was undertaken to elucidate roles of FGF receptor-1 (FGFR1) in the development of neural stem/progenitor-like cells (NS/PC). Cell surface FGFR1 stimulated proliferation of cultured nondifferentiated NS/PC. In contrast, FGFR1 that translocates to the cell nucleus stimulated NS/PC differentiation and associated gene activities. To determine the role of nuclear FGFR1 in NS/PC development in the brain we used ORMOSIL nanoparticles as a novel vector for *in vivo* gene transfection. Monodispersed nanoparticles, surface functionalized with amino groups were prepared. Stereotaxic injections of nanoparticles complexed with plasmid pEGFP into mouse brain lateral ventricle allowed us to visualize the extensive transfection and expression of enhanced green fluorescent protein in NS/PC-like cells of the subventricular zone. An *in vivo* fiber-based confocal imaging showed, in live animals, the transfection and retention of viability of the cells. Transfection of a plasmid expressing the nucleus targeting form of FGFR1, but not its tyrosine kinase deleted mutant, resulted in significant inhibition of the *in vivo* incorporation of bromodeoxyuridine into DNA of the cells in subventricular zone and adjacent rostral migratory stream. Thus the nuclear FGFR1 can control the proliferation of the NS/PC in this region of the brain. The ORMOSIL nanoparticles provide an effective gene delivery platform that may be used to elucidate and control molecular gene mechanisms that regulate development of brain NS/PC. Supported by J. Oishei Foundation, NIH/NS43621, and NSF DMR0318211 and IBN9728923.

**The Potential Roles of Local Delivery of Insulin on Re-epithelialization during Wound Healing**

Y. Liu,[1,2] X. Zhang,[2] Z. Zhang,[2] W. Xu,[2] M. Yao,[1] M. Martins-Green[1]; [1]Cell Biology & Neuroscience, University of California Riverside, Riverside, CA, [2]Burn Department, Ruijin Hospital Shanghai Second Medical University, Shanghai, China

Topical insulin application is beneficial in the healing of ulcerations and burns. However, the underlying mechanisms of its function have not been elucidated. To investigate the effects and mechanisms of insulin on re-epithelialization during the wound healing process, deep-partial thickness scald wounds were made in rats. The time and percentage of re-epithelialization in this model were evaluated. We found that lower doses (0.1μg) of locally-delivered insulin had a significant effect on re-epithelialization while not affecting systemic glucose levels. Insulin-treated burns heal much faster (22.67±3.01d) than those that are untreated (20±1.79d); the percentage of re-epithelialized wound area is significantly increased by lower dose of insulin applied at days 9 and 13 after wounding. Furthermore, we found that many more skin appendages were found with insulin treated wounds. To further decipher the cellular and molecular mechanisms of insulin function, we analyzed the effects of insulin on keratinocyte proliferation and migration. The percentage of keratinocytes in S phase is much higher with insulin treatment than without (39.50±12.7% versus 25.63±9.37%), and the percentage of cells in G2-M phase is markedly increased with insulin treatment (0.70±0.50% versus 1.38±0.60%, $P<0.05$) as well. Insulin treatment also induces keratinocyte migration. These results suggest that local delivery of insulin stimulates DNA synthesis, mitogenesis, and migration of keratinocytes. Furthermore, our data show that insulin treatment significantly increases the epidermis growth factor (EGF) mRNA levels in the early stages of re-epithelialization. This suggests that insulin may accelerate re-epithelialization during wound healing by stimulating EGF expression. Currently, we are performing studies to determine the molecular mechanisms involved in this process.

71

**Silencing of CCR5 Blocks the *Leishmania donovani* Entry into Murine Macrophages**

S. Majumdar, S. Majumdar (Bhattacharyya), R. Dey, N. Majumder, S. Bhattacharjee; Microbiology, Bose Institute, Kolkata, India

This study explores a possible therapeutic approach against visceral leishmaniasis by the gene silencing of chemokine receptor (CCR5). C-C chemokine receptor 5 (CCR5) plays a major role for parasitic entry into the macrophages. In our present study, we attempted to inhibit *Leishmania donovani* entry by blocking the CCR5 expression in primary murine macrophages as well as macrophage like cell lines (J774) using small interfering RNA (siRNA). We directly transfected two double-stranded siRNAs, designed against mouse CCR5 gene both into control and experimental macrophage culture before *Leishmania donovani* infection. We got significant silencing of CCR5 expression at 12hrs. and 24hrs. We observed significant increases in IFN-γ and IL-12 p40 mRNA synthesis at 12 hrs and 24 hrs as evidenced by semi-quantitative PCR. These findings suggest the potential for a novel therapeutic strategy by using CCR5 siRNA transfected in macrophages to boost the Th1 response against leishmanial pathogens.

72

**Nuclear Localization of the Human Prolactin Receptor via Residue Y587 Modulates Stat5a Phosphorylation, Transactivation and Localization**

S. L. Gadd, C. V. Clevenger; Pathology, Northwestern University, Chicago, IL

Prolactin (PRL) is necessary for the proliferation and maturation of the human breast. PRL activates the human PRL receptor (hPRLr), inducing the rapid phosphorylation of hPRLr, Jak2, and Stat5a, resulting in the nuclear localization and transcriptional activation of Stat5a. We have previously shown hPRLr in the nucleus of several different cell lines using biochemical and immunohistochemical assays. We also demonstrated a PRL-inducible association between nuclear hPRLr and Stat5a. The distal tyrosine residue of the rat long PRLr is involved in Stat5a association and activation; therefore, we mutated the distal tyrosine of hPRLr to phenylalanine (Y587F-hPRLr) and assayed the effect of this mutant on Stat5a

signaling. Preliminary co-immunoprecipitation studies demonstrated decreased association between the Y587F-PRLr and Stat5a compared to wild-type hPRLr. The Y587F mutation also resulted in decreased Stat5a phosphorylation and transactivation compared to wild-type hPRLr. Interestingly, nuclear localization of both Y587F-PRLr and Stat5a was decreased in cells expressing the Y587F mutant compared to wild-type hPRLr, suggesting that hPRLr and Stat5a enter the nucleus as a complex. To determine the direct effect of nuclear hPRLr on Stat5a transactivation, we replaced the ER leader sequence with a nuclear localization signal (NLS-hPRLr) and assayed the effect of this construct on Stat5a transactivation. In cells co-transfected with NLS-hPRLr and wild-type hPRLr, Stat5a transactivation increased two-fold over cells transfected with wild-type hPRLr alone, indicating that the effect of hPRLr on Stat5a transactivation is partially due to nuclear hPRLr. These findings support a functional role for the hPRLr at both the cell surface and the nucleus.

73

**Ligand-Independent Dimerization of the Human Prolactin Receptor Isoforms: Functional Implications**

S. L. Gadd, C. V. Clevenger; Pathology, Northwestern University, Chicago, IL

Prolactin (PRL) significantly contributes to the growth and differentiation of breast cancer. PRL acts at the molecular level by activating the prolactin receptor (PRLr), a transmembrane receptor belonging to the cytokine receptor family. The accepted view has been that PRL activates the PRLr by inducing dimerization of the receptor, but recent reports show ligand-independent dimerization of other cytokine receptors. Using co-immunoprecipitation assays, we have confirmed ligand-independent dimerization of the PRLr in T47D breast cancer and HepG2 liver carcinoma cells. In addition, studies performed in mammalian cells transfected with differentially epitope-tagged isoforms of the PRLr indicated that long, intermediate and deltaS1 PRLr isoforms also formed a complex in a ligand-independent manner. To determine the domain(s) involved in PRLr ligand-independent dimerization, we generated PRLr constructs as follows: (1) the TM-ICD, which consisted of the transmembrane (TM) domain and the intracellular domain (ICD) but lacked the extracellular domain, and (2) the TM-ECD, which consisted of the TM domain and the ECD but lacked the ICD. Mammalian cells transfected with differentially epitope-tagged TM-ICD and TM-ECD mutant PRLrs demonstrated ligand-independent dimerization of these constructs, implicating a significant role for the TM domain in this process. However, these truncated PRLrs were functionally inert alone or in combination in luciferase assays. Co-transfection studies using long hPRLr and the truncated mutants showed that TM-ECD inhibited long hPRLr signaling, whereas TM-ICD potentiated long hPRLr signaling in T47D cells, suggesting that a PRLr heterodimer in which one of the receptors lacks the ECD is capable of PRL signal transduction.

74

**Use of Cell Permeant TGFα Cytoplasmic Tail Peptides to Isolate in vivo Protein Complexes Containing the PDZ Scaffolding Protein MAGI-3 in MDCK Cells**

J. L. Franklin,[1] G. Bogatcheva,[2] J. Tam,[3] A. L. Ham,[4] R. J. Coffey[5]; [1]Cell and Developmental Biology, Vanderbilt University, Nashville, TN, [2]Medicine Epithelial Biology Program, Vanderbilt University, Nashville, TN, [3]Biomedical Sciences, The Scripps Research Institute East, Jupiter, FL, [4]Department of Biochemistry and Mass Spectrometry Research Center, Vanderbilt University, Nashville, TN, [5]Cell and Developmental Biology, Medicine, Epithelial Biology Program, Cancer Center, Vanderbilt University, Nashville, TN

The multiple PDZ-domain-containing membrane associated guanylate kinase inverted (MAGI) family of scaffolding proteins, which includes three mammalian members (MAGI's 1-3), have been shown to facilitate the interaction of many protein complexes with diverse cellular functions. We have shown that MAGI-3 binds to the EGF-receptor ligand, TGFα, through MAGI-3's PDZ1 with the type I PDZ target on TGFα, increasing TGFα's efficient secretion. In addition, localization of MAGI-3 in a cellular environment depends on cell-cell interactions, where in a polarized setting MAGI-3 is found along the lateral membrane and in the cytoplasm. Cell-cell contact increases MAGI-3's ability to enhance TGFα secretion perhaps by re-localizing MAGI-3 within the cell. To isolate protein complexes that contain TGFα and MAGI-3, we have utilized a biotinylated cell permeant TGFα cytoplasmic tail peptide that contains or lacks the C-terminal PDZ target (ETVV). We show that the TGFα cell permeant peptide can enter cells and interact stably with wild-type and variant GFP-tagged MAGI-3 in MDCK cells. This interaction requires both PDZ1 of MAGI-3 and the PDZ target on TGFα. Furthermore, it can be used to precipitate MAGI-3 through the biotin moiety on the peptide and isolate MAGI-3-containing complexes from a living cell. Specific MAGI-3 associated proteins isolated by this method have been identified. Several of these proteins contain PDZ-targets and are therefore good potential MAGI-3 interacting partners in TGFα-containing complexes. We are currently validating the association of these proteins with MAGI-3 and testing their roles in TGFα trafficking secretion and processing.

75

**Growth/Differentiation Factor-15 Knockout Mice Develop with Deficits in Distinct Neuronal Populations**

J. Strelau; Neuroanatomy, University of Heidelberg, Heidelberg, Germany

Growth/differentiation factor-15 (GDF-15) is a divergent member of the TGF-beta superfamily. In the CNS the choroid plexus epithelium represents the site of strongest expression in the neonatal and adult brain. Functional studies have demonstrated neurotrophic effects of the growth factor in vitro and in vivo. To further analyse the role of GDF-15 for the development and maintenance of neurons in the CNS we generated a GDF-15 deficient mouse line, where the GDF-15 encoding DNA sequence was replaced by the lacZ gene. Using in situ hybridization and X-Gal staining we found lacZ expression in the subventricular zone of the developing spinal cord in and in the hem region of the embryonic cerebral cortex. In parallel we started to quantify the numbers of midbrain dopaminergic neurons, noradrenergic neurons in the locus coeruleus and motoneurons in different brain stem nuclei and the lumbar spinal cord. We compared 30-week-old wild-type and GDF-15 deficient mice using tyrosine hydroxylase immunohistochemistry and cresyl violet staining. We found a significant reduction of 11% in the number of TH+ neurons in the substantia nigra. Densities of striatal TH+ fibers were reduced by 11.5%. No difference was observed in the number of TH+ neurons in the locus coeruleus, indicating that reduction in TH+ fibers is due to deficits in the dopaminergic system. Notably, the number of trigeminal, facial and spinal (L1-L6) motoneurons in GDF-15 deficient mice was reduced by 20%. Oculomotor and hypoglossal motoneurons were not affected. As neonatal mice show no difference in the number of facial motoneurons we assume that the motoneuron loss occurs postnataly. Taken together we suggest that GDF-15 constitutes a novel neurotrophic factor for motoneurons and midbrain dopaminergic neurons. Supported by Deutsche Forschungsgemeinschaft (Str616/3-4 and SFB 636)

**The $Ca^{2+}$ Dependent Protease Calpain-1 is Responsible For the C-terminus Cleavage of Fz-7 in Endothelial Cells**

I. T. Struewing, C. D. Mao; GCNS, University of Kentucky, Lexington, KY

Frizzled receptors are a family of seven transmembrane domains G-protein-coupled receptors that are activated in particular by Wnt proteins. Once activated, they may elicit three signaling pathways: Wnt/β-catenin, planar cell polarity, or $Ca^{2+}$/Protein Kinase C. Among them, Fz-7 has been shown to be involved in cell migration during gastrulation and neuronal migration in *Xenopus* and Zebrafish development, as well as in tumor cell migration. We have found that Fz-7 is expressed in endothelial cells, and have used an Fz-7 construct dually tagged at the N and C-termini to determine its role and regulation in endothelial cells. During endothelial cell migration and adhesion Fz-7 is asymmetrically distributed at the plasma membrane as shown using immunofluorescence confocal microscopy. While full length Fz7 receptors are found in the endoplasmic reticulum(ER) and at the plasma membrane, some intracellular vesicles are only positive for the Fz7 C-terminus. Western blot analysis of Fz7 forms has revealed a novel 10 kDa C-terminus cleaved fragment that is detectable for wild-type Fz-7 and Fz-7 mutant forms trafficking to the plasma membrane, but not for Fz-7 mutant forms retained in the ER ruling out an ER-associated degradation. This Fz7 C-terminus cleavage is up-regulated by the $Ca^{2+}$ ionophore ionomycin and the PKC activator PMA, and increases with cell density. Fz-7 C-terminus cleavage is decreased by the calpain inhibitors calpeptin and Z-LL-CHO. Co-transfection with a dominant negative form of Calpain-1 greatly reduces both basal and PMA-stimulated levels of Fz-7 C-terminus cleavage. Altogether these results reveal that the C-terminus cleavage of the Fz-7 receptor is regulated by $Ca^{2+}$-dependent events, such as cell adhesion, and is dependent on Calpain-1 activity. This specific C-terminus cleavage may represent a down-regulation mechanism of Fz-7 receptors at the plasma membrane after activation.

77

**OGF-OGFr Axis and Its Inhibitory Actions on Cell Cycle Progression of Head and Neck Cancer**

F. Cheng,[1] I. S. Zagon,[1] M. F. Verderame,[2] P. J. McLaughlin[1]; [1]Department of Neural and Behavioral Sciences, The Pennsylvania State University College of Medicine, Hershey, PA, [2]Department of Medicine, The Pennsylvania State University College of Medicine, Hershey, PA

Opioid growth factor (OGF) is an endogenous opioid peptide ([$Met^5$]-enkephalin) that interacts with the OGF receptor (OGFr), and serves as a tonically active negative growth factor in neoplasia. Previous studies showed that OGF inhibits the growth of human squamous cell carcinoma of the head and neck (SCCHN) *in vitro* and *in vivo*, and is targeted to cell proliferation. To clarify the mechanism by which OGF inhibits cell replication, we investigated the effect of OGF on cell cycle activity in the SCCHN cell line SCC1. In cultures synchronized with nocodazole, flow cytometry revealed that OGF treatment resulted in fewer cells exiting the G1 phase of the cell cycle in comparison to controls. Focusing on the role of OGF in the G1 to S phase transition, OGF decreased the phosphorylation of retinoblastoma protein (Rb) without changing the total Rb expression. This change was correlated with reduced cdk4 kinase activity while the total cdk4 expression did not change. OGF treatment induced cyclin-dependent kinase inhibitor (CKI) p16 protein expression but had no effect on p21 or p27 protein expression. Short-term blockade of OGF-OGFr interactions with the short-acting opioid antagonist, naloxone (NAL), revealed that increased expression of p16 protein by OGF was completely abolished by NAL. Inhibition of p16(INK4a) activation by p16 specific siRNA blocked OGF inhibiting action on SCC1 cells. Collectively, these results indicate that the receptor-mediated, growth inhibitory effects of the OGF-OGFr axis in SCC1 cells are associated with induction of p16 expression, that in turn, repress the activity of cyclin D1/cdk4 and Rb phosphorylation.

78

**The OGF-OGFr Axis is a Determinant of Corneal Wound Healing: Molecular Perturbations and Repercussions**

I. S. Zagon,[1] J. W. Sassani,[2] M. F. Verderame,[3] P. J. McLaughlin[1]; [1]Neural and Behavioral Sciences, H109, Penn State University, Hershey, PA, [2]Ophthalmology, Penn State University, Hershey, PA, [3]Medicine, Penn State University, Hershey, PA

Blockade of OGF from the OGF receptor by the opioid antagonist naltrexone (NTX) results in acceleration of corneal re-epithelialization in rat, rabbit, and human. To test whether this pharmacological effect of NTX is related directly to the OGF-OGFr axis, biolistic DNA delivery by particle-mediated gene transfer using a gene gun was utilized to deliver antisense OGFr gene to the corneal epithelium of adult rats. Disruption of the OGF-OGFr axis would be predicted to accelerate corneal wound healing if this peptide and receptor complex played a direct role in re-epithelialization. The plasmid pcDNA3.1-OGFr, carrying the rat OGFr cDNA under the control of the CMV immediate early promoter, was delivered twice at 300 psi into one eye of each rat (AS rats); empty vectors were transfected into one eye of another group of animals (EV rats). This regimen resulted in >90% transfection of the central and peripheral corneal epithelium without penetration into the stroma. After a 24-hr latency, a corneal abrasion was created using a 3 mm trephine. Corneal wounds were tracked photographically with fluorescein dye, and images quantitated using Optimas software. At 16 hr after wounding, the residual defect was 40% smaller for AS rats than for EV rats ($p<0.05$). After 24 hr, the defect in rats transfected with antisense was 98% smaller than for EV animals ($p=0.03$). Rats injected with BrdU to determine DNA synthesis rates showed significantly a greater number of BrdU labeled cells in AS rats relative to EV animals. These data reveal that the OGF-OGFr axis is crucial to determining the outcome of corneal wound healing. Moreover, gene gun technology supports the use of gene therapy for ocular diseases.

**Salvianolic Acid B and Magnolol Inhibit Vascular Smooth Muscle Cell Proliferation and Migration by Stromal Cell-Derived Factor-1 Alpha**

C. J. Wu, C. Chen; Biological Science and Technology, China Medical University, Taichung, Taiwan Republic of China

Atherosclerosis is a disease with complex processes in which monocytes and lymphocytes are recruited form the blood into the arterial intima. Stromal cell-derived factor-1alpha (SDF-1alpha) and its unique receptor, CXCR4, have been recently implicated in the development of neoitimal formation after vascular injury in apolipoprotein E-deficient mice. In the present study we investigated two Chinese herbal extracts, salvianolic acid B and magnolol, about their inhibitory effects on rat vascular smooth muscle cells (VSMCs) for cells proliferation, CXCR4 expression, cellular migration and its related signal pathway. Our results demonstrated that SDF-1alpha-induced cell proliferation can be significantly inhibited by salvianolic acid B and magnolol. Cell migration potentiated by SDF-1alpha was also attenuated by salvianolic acid B and magnolol. In the aspect of apoptosis, salvianolic acid B and magnolol can induce VSMCs apoptosis via caspase 3 up-regulation or Bcl-2 down-regulation. In summary,

considering their effects on cell proliferation and migration, salvianolic acid B and magnolol may play an important role in preventing atherosclerosis and balloon injury-induced neoitimal formation.

### RAGE Engagement in Myoblasts Modulates Proliferation, Apoptosis, Adhesiveness, Migration and Invasiveness

G. Sorci, F. Riuzzi, R. Donato; Dept Exp Med & Biochem Sci, University of Perugia, Perugia, Italy

We reported that RAGE (receptor for advanced glycation end products), a multiligand receptor of the immunoglobulin superfamily expressed in myoblasts, when activated by its ligand amphoterin (HMGB1), stimulates rat L6 myoblast differentiation via a Cdc42-Rac-MKK6-p38 MAPK pathway, and that RAGE expression in rat skeletal muscle tissue is developmentally regulated (1). We show here that inhibition of RAGE function via overexpression of a signaling-deficient RAGE mutant (RAGEΔcyto) results in increased L6 myoblast proliferation, migration and invasiveness, and decreased apoptosis and adhesiveness, while myoblasts overexpressing RAGE behave the opposite, compared with mock-transfected myoblasts. These effects are accompanied by a decreased induction of the proliferation inhibitor $p21^{WAF1}$ and expression of adhesion molecules known to be important for myogenesis, increased induction of cyclin D1, extent of Rb, ERK1/2 and JNK phosphorylation and activity of matrix metalloproteinases 1 and 2 in L6/RAGEΔcyto myoblasts, while the opposite occurs in L6/RAGE myoblasts, compared with mock-transfected myoblasts. Neutralization of culture medium amphoterin negates all effects of RAGE activation, suggesting that amphoterin is the RAGE ligand involved in the RAGE-dependent effects in myoblasts. Effects of RAGE signaling in myoblasts appear to depend on p38 MAPK activation only, because the p38 MAPK inhibitor, SB203580, reduces them in both L6/RAGE and L6/mock myoblasts, and a similar reduction is observed in L6/RAGE and L6/mock myoblasts transiently transfected with MKK6AA, an inactive mutant of the upstream p38 MAPK, MKK6. Thus, the amphoterin/RAGE pair stimulates myoblasts differentiation by the combined effect of inhibition of proliferation and stimulation of differentiation. Also, based on the findings reported here, we speculate that deregulation of RAGE expression and/or function might contribute to the increased motility and invasiveness of myoblast neoplastic counterparts.1. Sorci G. et al. (2004) Mol. Cell. Biol. 24:4880-4894.

### Complementary Roles of IL-8 and VEGF in Inflammation, Angiogenesis and Healing

M. Yao, M. Petreaca, M. Martins-Green; Cell Biology & Neuroscience, UCR, Riverside, CA

Inflammation is invariably accompanied by angiogenesis but it is not known how angiogenic factors present during the inflammatory phase of wound healing, are involved in inflammation-induced angiogenesis. Here, we address the contribution of two such factors, interleukin-8 (IL-8/CXCL8) and VEGF, in this process. IL-8 levels increase rapidly after wounding in rabbits, reaching maximal levels at 24hrs, whereas VEGF peaks at 3 days. The time course of the infiltration of inflammatory cells and production of new blood vessels after wounding was also determined. Neutrophils were markedly increased 4hr after wounding, and their level peaked at 24hr. Monocyte/macrophage infiltration peaked at 48hr and decreased by day 4. The number of blood vessels was significantly increased by day 3, continued to increase through day 5 and peaked between days 7 and 14. In order to determine the contributions of IL-8 and VEGF to inflammation and angiogenesis, we performed the wounding experiments in the presence and absence of their antibodies or antibodies/inhibitors to their receptors. Inhibition of IL-8 or its receptors blocked development of early stage microvessels but did not inhibit late-stage vessels; in contrast, VEGF/VEGFR antibodies blocked the late stage without altering the early stage. Furthermore, whereas inhibition of IL-8 resulted in decrease of infiltration of inflammatory cells, inhibition of VEGF resulted in significant increase in macrophages in the wound tissue. We found that VEGF induces apoptosis of macrophages in human cultures. Using FACS analysis and Annexin-V antibodies, we show that the number of dead cells in VEGF-treated macrophages was significantly higher than control and that the maximum effect occurred at 24hrs after treatment. We are currently investigating the signaling pathways involved. Our results suggest that IL-8 and VEGF play complementary roles in inflammation and angiogenesis during wound healing.

### A New Synthetic Tripeptide that Promotes Cell Activation in Epidermal Cells

N. Domloge, K. Cucumel, J. Botto, C. Dal Farra; Vincience, Sophia antipolis, France

When cell membrane-related receptors are activated, they trigger a second messenger responsible for a subsequent cascade of cellular responses. This general process is one of the most important mechanisms of cell activation and signal transduction. To understand further the relationship between cell activation and cell aging, we developed a synthetic tripeptide, and tested its effects on cell activation. Cellular ATP assessment of human fibroblasts treated with 1% of the peptide, revealed an increase in cellular ATP level. This increase started within 5 minutes, and reached its maximum 15 minutes after the peptide was administered. Together with the peptide structure, this activation suggests that the peptide directly stimulates APnA (ATP reservoir molecules) receptors in the cells. Moreover, as Ca2+ plays a central role in cell signalling, we also evaluated the effect of the peptide on cellular Ca2+ level. Using a fluorescent probe and confocal microscopy, we monitored Ca2+ expression in selected single HaCaT cells in response to peptide administration. The selected cells elicited maximum fluorescence intensity 90 s after the peptide was administered, and dropped down to basal level thereafter. Further studies on keratin synthesis confirmed these results and additional tests on *in vitro* wound repair and protein synthesis confirmed general cell activation by the new peptide. In addition to the tripeptide's great similarity to the described APnA receptor, these results strongly suggest that the structure of the tripeptide is responsible for ATP induction. The peptide also shows evidence of cell activation via other G-protein-coupled receptors in epidermal cells. Within the context of topical skin regenerating and energizing products, these set of studies demonstrate that the new tripeptide possesses an effect on cell activation that can be of great use.

### Ric-8B, a Potential Regulator for Galpha-olf

L. von Dannecker, A. F. Mercadante, B. Malnic; Departamento de Bioquímica, Instituto de Química - USP, São Paulo, Brazil

The olfactory system is able to recognize and discriminate a vast array of chemical structures. Odorants activate specific odorant receptors (ORs) expressed in the cilia of olfactory neurons. As a consequence Galpha-olf is activated and the olfactory neurons are depolarized via cyclic-AMP

increase. In order to search for potential regulators for Galpha-olf we used yeast two-hybrid to screen an olfactory epithelium cDNA library with Galpha-olf as bait. We found that Ric-8B, a putative GTP exchange factor, is able to interact with Galpha-olf. We performed Northern blot and RT-PCR experiments to examine the tissue distribution of Ric-8B expression. Our data show that Ric-8B gene is preferentially transcribed in the olfactory epithelium and, to a lower extent, in the brain, eye, and muscle. We performed *in situ* hybridization experiments to determine the localization of Ric-8B and Galpha-olf in the olfactory epithelium and found that they are coexpressed in mature olfactory neurons. Recent experiments showed that expression of Ric-8B in the olfactory epithelium follows Galpha-olf time course expression profile with the initial detection for both genes in embryonic stages at prenatal day 16 (E.16). We also performed *in situ* hybridization to determine the distribution of Ric-8B mRNA in the brain. Ric-8B mRNA was colocalized with that of Galpha-olf, except for the Purkinje cells in the cerebellum. To verify whether Ric-8B is able to regulate the activity of Galpha-olf, we transfected HEK293 cells with the expression vectors for Galpha-olf, Ric-8B and the receptors Beta-2-AR or D1R. Our results show that Ric-8B is able to potentiate the ability of Galpha-olf to activate cAMP production if receptors were previously activated. The potentiation of Galpha-olf by Ric-8B and their highly restricted and colocalized expression patterns strongly indicate that Ric-8B is a potential regulator for Galpha-olf.

84

**Actin Cytoskeleton-dependent Control of Rho Activation: Role of p190 RhoGAP and Filamin**

A. Mammoto, S. Huang, D. E. Ingber; Vascular Biology Program, Children's Hospital/Harvard Medical School, Boston, MA

Cell shape-dependent control of cell cycle progression plays an important role in the spatial heterogeneity of proliferation that drives tissue morphogenesis. We previously showed that the small G protein Rho mediates cell shape-dependent control of cell cycle progression in human capillary endothelial (HCE) cells (Mammoto et al. J.Biol.Chem. 279:26323, 2004). Rho activation by growth factors has been intensively studied, however, little is known about how cytoskeletal distortion regulates Rho activity. Rho activity is increased in adherent HCE cells that were induced to round up by treatment with the actin cytoskeletal disruptor, cytochalasin D (cytoD) or by placing the cells in suspension, whereas it remained low in spread adherent cells. To elucidate the mechanism by which Rho activity senses cell shape we now show that the Rho GTPase-activating protein, p190RhoGAP, which inactivates Rho, conveys the effects of cytoskeletal configuration on cell shape on Rho activity. p190RhoGAP was translocated to the lipid raft fraction when cells were spread, whereas this translocation was inhibited in suspended cells and cytoD-treated cells. p190RhoGAP tyrosine phosphorylation appeared within the raft fraction in spread cells. Interestingly, cell rounding fails to exclude p190RhoGAP from the rafts and to increase Rho activity in cells that lack filamin. These data indicate that changes in the structural configuration of the actin cytoskeleton impact Rho activity by controlling p190RhoGAP translocation to lipid rafts and that filamin represents a central control point in this pathway. This finding provides a handle to study how a macroscopic parameter, cell shape, is translated into intracellular biochemical signals that govern how cells make cell fate decisions in the physical context of the tissue.

85

**GTP-like Conformation of GDP-bound Arl10b GTPase**

A. Atanassova,[1] J. Choe,[1] S. Dimov,[1] Y. Shen,[1] A. Botchkarev,[1] J. Lew,[1] I. Kozieradzki,[1] H. Park[2]; [1]Structural Genomics Consortium, University of Toronto, Toronto, ON, Canada, [2]Structural Genomics Consortium, Department of Pharmacology, University of Toronto, Toronto, ON, Canada

ADP-ribosylation factor (ARF) proteins are Ras-like small G proteins with the molecular weight of 20 kDa. They include ARF, Arf-like (ARL) and Secretion-associated and Ras-related (SAR) proteins, all of which are collectively called the ARF family proteins. The GDP/GTP (inactivation/activation) cycle of the ARF family proteins has been known to cause conformational changes at the N-terminal helix as well as the nucleotide-interacting switch 1 and 2 regions. Here, we solved the structure of ARL10B protein, which contains a truncation of the N-terminal helix, by the x-ray crystallographic technique. The truncation of the N-terminal helix mimics its interactions with lipid membrane. The structure shows an active conformation similar to the GTP-bound state of other ARF proteins although ARL10B is still bound to GDP. This finding suggests that the N-terminal helix interactions with lipid membrane, not the GDP-GTP exchange, trigger the conformational switch of ARL10B from the inactive to the active state. Important implication of this activation mechanism is that the activation of ARL10B proceeds with a conformational switch to the GTP-like state via the N-terminal helix recruitment to membranes, leading to the GDP-GTP exchange by a classical guanine nucleotide exchange factor.

86

**A Ciliary Sensation: Mapping Components of the GTP Signaling Pathway in *Tetrahymena thermophila***

H. G. Kuruvilla; Science and Mathematics, Cedarville University, Cedarville, OH

*Tetrahymena thermophila* are an excellent model system in which to study chemokinesis because of their ease of growth in culture as well as their adaptability to behavioral and biochemical assays. Recent work by Christensen *et al.* (2003), as well as Csaba *et al.* (2004) suggests that the cilia of this organism may actually serve as signaling apparatus, allowing for chemokinesis to take place. Both of these prior studies were done with chemoattractants. In our current study, we have used immunofluorescence labeling to map components of the GTP chemorepellent pathway in *Tetrahymena*. Our data show that many enzymes involved in the chemorepellent pathway, including tyrosine kinase and PP2A, immunolocalize to the cilia. These data further confirm the hypothesis that cilia may serve as signaling organelles in *Tetrahymena*, in addition to their roles in motility and chemokinesis.

87

**Snapin, a SNARE-Associated Protein, Interacts with the Type VI Adenylyl Cyclase at Postsynaptic Sites**

C. J. Wu, J. Chou, A. C. Hung, H. Chang, C. Huang, H. Lai, Y. Chern; Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan Republic of China

Snapin is a binding protein of SNAP25 (synaptosome-associated protein -25), a component of the SNARE (soluble N-ethylmaleimide-sensitive fusion protein attachment protein receptor) complex. It has been suggested to be important in mediating neurotransmitter release process through its modulation of the interactions between the SNARE complex and synaptotagmin. In the present study, we identified Snapin as a novel interacting protein of type VI adenylyl cyclase (ACVI) by yeast-2-hybrid screening. Mutational analysis showed that the interaction domains of

ACVI and Snapin were located within amino acids 1-86 of ACVI and 33-51 of Snapin, respectively. Expression of Snapin specifically eliminated protein kinase C (PKC)-mediated suppression of ACVI, while it had no effect on cAMP-dependent protein kinase (PKA) or calcium mediated suppression of ACVI. Since the cAMP-dependent pathway has been implicated in neurotransmitter release, and phosphorylation of Snapin by PKA enhances its interaction with the SNARE complex, direct interactions between Snapin and ACVI may facilitate the release process induced by cAMP. Immunofluorescence staining showed co-localization of Snapin and ACVI in primary hippocampal neurons. Using MAP2 as a somatodendritic marker, the ACVI/Snapin complexes were located in somas and proximal dendrites. In addition, we showed that ACVI/Snapin complexes also co-localized with 2-amino-3-(3-hydroxy-5-methylisoxazol-4-yl) proprionate (AMPA) receptors, N-methyl-D-aspartate (NMDA) receptors, and postsynaptic density-95 protein (PSD-95). This observation suggests that, apart from presynaptic regulation of neurotransmitter release, the ACVI/Snapin interaction may be functionally important at postsynaptic sites. Together, these data suggest that the ACVI/Snapin interaction might play a role in cAMP-mediated neuronal plasticity.

88

**Understanding the Conformational Change in a Protein Kinase C Probe**

C. Jost, J. Brumbaugh, A. Schleifenbaum, A. Guinan, T. Skrahina, C. Schultz; Gene Expression, EMBL Heidelberg, Heidelberg, Germany

We recently developed a FRET based probe (KCP-1) which monitors PKC activity in living cells. (Schleifenbaum *et al., J. Am. Chem. Soc.*, 2004) The probe is based on pleckstrin, the major PKC substrate in platelets, and changes its conformation upon phosphorylation. The conformational change in the construct EYFP-PH1-substrate-DEP-GFP$^2$ is indicated by a change in emission ratio between the two fluorophores. To understand the nature of the conformational change, we studied two regions of KCP-1 more intensively: the N-terminal linker region between pleckstrin and YFP and the C-terminal linker region between pleckstrin and GFP$^2$. The C-terminal linker region of KCP-1 contains a stretch of acidic amino acids (acidic loop). By deleting this acidic loop we obtained a new probe (KCP-2) which showed the reverse effect to KCP-1: the FRET ratio decreased by 20-40% instead of an increase. Subsequent systematic studies of the linker region showed that most charged residues were essential for the performance of KCP-1. In addition, other crucial residues were identified, e.g. V235. Elongation of the linker region had little effect on KCP-1. Similar elongations or shortening of the N-terminal linker region of the PH domain showed that KCP-1 was very sensitive to any kind of alteration, while KCP-2 was unaffected. For example, the KCP-1 signal was reduced to 20% of the original with 6 additional amino acids, while KCP-2 still showed up to 80% activity. We conclude that in KCP-1, both the acidic loop and the N-terminal linker region are involved in producing the complex conformational change induced by phosphorylation. On the other hand, the shorter probe, KCP-2, seems to rely entirely on the interaction between the PH1 and DEP domains of pleckstrin.

89

**Interaction between PKC and HSP 70 in Fibroblasts Overexpressing Cellular Ras**

C. O'Brien, S. K. Murphy; Biological Sciences, University of the Sciences in Philadelphia, Philadelphia, PA

Heat shock proteins are a conserved group of proteins involved in cell regulation. Constitutively produced HSP 70 acts as a molecular chaperone. HSP 70 can also be induced by environmental stressors. Overexpression of HSP 70 has been shown to increase resistance to apoptosis through interaction with signaling pathways, possibly implicating HSPs in carcinogenesis. Previously we showed that fibroblasts overexpressing cellular Ras had elevated HSP 70 relative to controls. Ras expressing cells exhibited a transformed phenotype that was reversed by inhibition of HSP 70. Further, Ras expressing cells show increased activity of $PIP_2$-PLC. HSP 70 inhibition did not alter this, suggesting HSP 70 acted downstream of $PIP_2$. Protein kinase C (PKC) plays a role in growth regulation and cytoskeletal organization. Additionally, PKC phosphorylates HSF-1 which is essential for HSP 70 transcription. We propose that PKC and HSP 70 are involved in a positive feedback loop in which PKC phosphorylates HSF-I inducing HSP 70. In turn, HSP 70 prevents down regulation of PKC. Further, that this feedback works to regulate Ras function. To that end, we have shown that activation of PKC resulted in a 100% increase in HSP 70. Conversely, inhibition of PKC led to a 40% decrease in HSP 70 expression. To further support our hypothesis we have shown a correlation between elevated PKC activity, increased expression of HSP 70 and the transforming capabilities of Ras. Concomitant with an increase in PKC activity and subsequent increase in HSP 70 expression we have observed an increase in $^3$H-thymidine incorporation and disruption of the cytoskeleton. These conditions were reversed in the presence of both PKC and HSP 70 inhibitors. These data suggest that PKC and HSP 70 interact via positive feedback and contribute to the ability of Ras to transform cells.

90

**Studies on the Cell Activation and Signaling Properties of Diacylglycerol-Rich Extract**

C. Dal Farra, E. Bauza, C. Coquet, N. Domloge; Vincience, Sophia antipolis, France

PKC phosphorylation and activation by diacylglycerol (DAG) induces a variety of essential cellular responses. This mechanism results from an important cellular signaling pathway involving tyrosine kinase receptor activation. In this area, we developed a new DAG-rich extract in an effort to induce direct and rapid cell activation. In these studies, we tested the effect of DAG-rich extract on cultured human epidermal cells and fibroblasts, and confirmed the consequential activation of terminal differentiation following cell activation by the extract. First, immunofluorescence studies on protein expression were performed. These studies revealed that application of the DAG-rich extract to fibroblasts enhanced fibronectin, collagen I, and collagen III synthesis. Second, studies on HaCaT cells showed that DAG-rich extract-treated cells exhibited enhanced beta 1 integrin expression. HaCaT studies also revealed an increase in filaggrin expression, a marker of terminal differentiation. This increase in filaggrin was found in a dose-dependent manner. Immunoblotting studies demonstrated that PKC activation by DAG-rich extract is accompanied by an increase in the expression of differentiation markers and by an increase in protein synthesis. Studies on ex vivo skin confirmed these findings. Interestingly, ATP evaluation studies revealed that administration of the extract resulted in an increase in cellular ATP level. Moreover, studies on Ca2+ expression in selected single cells showed an increase in Ca2+ in response to extract administration. These results studies lend strong support to the hypothesis that in addition to PKC, DAG-rich extract activates other cell targets as well.Taken together, these studies demonstrate important properties possessed by DAG-rich extract through its combination of different essential cell activation and signaling mechanisms. In the context of energizing and anti-aging skin care products, these results reveal that DAG-rich extract is an active ingredient that can be of great use.

91

**A Comparison of a Novel Serum and Glucocorticoid Inducible Kinase 1 (SGK 1) Isoform within Human Keratinocytes**

B. A. Hall, S. Blakeley, T. R. Jackson; Dermatological Sciences, University of Newcastle Upon Tyne, Newcastle Upon Tyne, United Kingdom

Serum and Glucocorticoid inducible kinases (SGKs) form a group of serine/threonine kinases implicated in the transduction of cell survival and proliferation signals to the nucleus. Although mechanisms of regulation of SGK activation and expression in response to extracellular stimuli are not well understood [1]. SGKs encode a kinase domain 54% similar to the well studied kinase, Akt. As with the closely related homologue Akt, SGKs are thought to depend on phosphoinositide-3 kinase (PI-3K) for enzymatic activation. Both kinases require phosphorylation of two regulatory sites at specific Thr and Ser residues by phosphoinositide-dependent protein Kinases 1 and 2 (PDK1 and PDK2) [2]. Initial aims were to charactise the expression of SGKs within primary human keratinocytes and assess their subcellular localisation. Initial data has identified specific subcellular structures in which SGK1 localises. By use of Fluorescence Recovery After Photobleaching (FRAP) we have investigated the dynamics of eGFP-SGK1 associated with these structures in living cells. Furthermore, herein we report the discovery of a novel SGK1 variant. The use of western blotting and molecular cloning techniques confirms the serum and glucocorticoid inducibility of this variant. **Cell-Based Assays for the Simultaneous Monitoring of the Akt Pathway by Multiplex Bead Immunoassay**

T. Hager, W. Zheng, J. DeSimone, C. Fountain, J. Wang, K. Reagan; BioSource International, Camarillo, CA

The insulin receptor (IR)/IGF-1R - Akt signaling pathway is crucial for regulating cell survival, proliferation and a number of metabolic effects of insulin. Perturbations in this pathway are suspected of being key indicators and perhaps the root cause of diseases such as cancer and diabetes. Several important proteins along the pathway have been identified and their activation state monitored by detecting phosphorylation status of specific sites. A method to measure the activity of these proteins simultaneously will significantly expedite the drug discovery process targeting this pathway. In this study, MCF7 and 3T3L1 cells were treated with IGF-1 or insulin at different time intervals. The phosphorylation states of seven proteins (IR [pYpY1162/1163], IGF-1R [pYpY1135/1136], IRS-1 [pS312], Akt [pS473], GSK-3β [pS9], PRAS40 [pT246], p70S6K [pTpS421/424]) were monitored concurrently using a multiplex bead immunoassay. The results illustrate that insulin and IGF-1 activate different components along the Akt pathway in a time-dependent manner. Prolonged treatment of cells with insulin and IGF-1 induces a negative feedback regulation through phosphorylation of IRS-1 at Serine 312. The inhibitory effects of the PI3 kinase inhibitor, wortmannin, and Akt inhibitors, SH-5 and SH-6, on insulin and IGF-1 signaling were observed, showing the down-regulation of Akt [pS473], GSK-3β [pS9], PRAS40 [pT246] and p70S6K [pTpS421/424]. Our results demonstrate that simultaneous monitoring of insulin/IGF-1 signaling through downstream members of the Akt pathway allows a more complete cell-based analysis of relevant, disease-related signal transduction mechanisms and provides a valuable tool for research and drug discovery.

93

**Direct Regulation of Cell Cycle Proteins by Transforming Growth Factor-β**

D. V. Kielley, J. J. E. Doré; Basic Medical Science, Memorial University of Newfoundland, St. John's, NF, Canada

**Introduction:** Transforming growth factor β (TGF-β) causes growth stimulation in fibroblasts, and growth inhibition in epithelial cells. To explain how TGF-β exerts different growth effects, we investigated the phosphatidylinositol 3-kinase (PI3K)/ Akt pathway. We propose that PI3K signalling is partially responsible for different phenotypic effects of TGF-β on mesenchymal and epithelial cells, in conjunction with the previously described Smad pathway. **Methods**: Western blotting was used to describe temporal changes (0-3 hours) in endogenous phosphoinositide-dependent kinase (PDK-1), Akt, Glycogen Synthase Kinase-3β (GSK-3β) and Cyclin D1 phosphorylation following TGF-β2 stimulation of normal epithelial and fibroblast cell lines. **Results:** TGF-β stimulation increased PDK-1, Akt and GSK-3β phosphorylation in fibroblasts over time, while it decreased PDK-1, Akt and GSK-3β phosphorylation in epithelial cells over the same time. The GSK-3β substrate, Cyclin D1, exhibited decreasing phosphorylation in fibroblast cells and decreased protein levels of Cyclin D1 in epithelial cells. In fibroblasts, TGF-β increased Cyclin D1 complex formation with CDK-4 and nuclear localization. Conversely, TGF-β decreased complex formation in epithelial cells. TGF-β stimulated Cyclin D1/CDK complex formation was blocked by a PI3K inhibitor. **Conclusions:** In total, these results define a novel pathway for TGF-β regulation of cell cycle through PI3K/Akt in normal cells. This signalling pathway also differentiates epithelial and fibroblast cell responses to TGF-β stimulation. In conjuction with Smads, this pathway could account for the cell type specific growth responses to TGF-β. Potential alterations of this pathway may be a mechanism by which some cancers elude the normal growth regulatory system imposed by TGF-β.

94

**Insulin-stimulated Interaction between Insulin Receptor Substrate 1 and p85α and Activation of Protein Kinase B/Akt Require Rab5**

X. Su, P. D. Stahl; Department of Cell Biology and Physiology, Washington University, St. Louis, MO

Insulin resistance represents the leading factor for the development of type 2 diabetes. Binding of insulin to the insulin receptor (IR) initiates a cascade of protein phosphorylation events that lead to the activation of multiple distinct signaling pathways. Previous studies suggested that receptor endocytosis and trafficking affected different receptor signaling pathways. The small GTPase Rab5 is required for receptor-mediated endocytosis at multiple sites including the fusion of newly formed vesicles with early endosomes. Three Rab5 isoforms have been identified. Herein, we exploited the RNA interference (RNAi) technique to specifically knock-down Rab5 isoforms to determine the function of Rab5 in distinct insulin signaling pathways. siRNA against individual Rab5 isoforms had no effect on Akt and MAPK activation by insulin in NIH 3T3 cells over-expressing human IR (NIH 3T3/hIR). However, knockdown of all three Rab5 isoforms dramatically inhibited Akt activation by insulin without affecting MAPK activation. This inhibition of Akt activation was due to the impaired interaction between insulin receptor substrate1 (IRS1) and the p85α subunit of PI3K, which is known to be activated by insulin. These results indicate that Rab5 is required in the recruitment of p85α by IRS1. Interestingly, expression levels of all three Rab5 isoforms are dramatically down regulated in white adipocyte tissues (WAT) of fatty Zucker rats. Collectively, the present study suggests the involvement of Rab5 and endocytosis in obesity-induced insulin resistance and diabetes.

**PRC17, a Rab5 GTPase Activating Protein, Alters the Normal Trafficking and Signaling of EGFR**

M. Wainszelbaum, D. Hodzic, C. Kong, A. Charron, P. D. Stahl; Cell Biology & Physiology, Washington University Medical School, St. Louis, MO

PRC17 (Prostate cancer Chromosome 17) is a "primate specific" oncogene found in chromosome 17 that is over-expressed in selected metastatic prostate, breast tumors and tumor cell lines. It interacts with Rab5 and has Rab5 GTPase activating protein (GAP) activity. Rab5 plays a key role in vesicular trafficking from the plasma membrane to the sorting endosomal compartment. Moreover, Rab5 is involved in both Epidermal Growth Factor Receptor (EGFR) signaling and trafficking. Here we studied the molecular biology of PRC17 and the effects of the protein on EGFR mediated endocytosis and signaling. Examination of the human genome database indicates that PRC17 gene exists as 8 copies with high homology encoding isoforms that vary in a small number of amino acids nested in the GAP domain. The relative tissue abundance of PRC17 was estimated by Semi-quantitative PCR from a set of human cDNAs. Expression levels of PRC17 were comparable among the tissues tested with the exception of skeletal muscle that exhibited a low abundance. By RFLP we identified the expression of at least three isoforms and two spliced variants in those tissues. Over-expression of two different isoforms of PRC17 in cultured cells, using a retroviral system, resulted in accelerated cellular growth and in enhanced proliferation in response to EGF stimulation. MAP kinase and PKB/Akt activation responses to EGF in PRC17 transfected cells was substantially greater both in magnitude and in duration. Furthermore, EGF receptor binding and internalization was substantially increased in PRC17 transfected cells. Lastly, we found a substantial delay in EGF receptor degradation following receptor internalization in cells expressing PRC17. Our results suggest that PRC17 enhances growth factor receptor signal transduction by altering the normal trafficking of internalized receptors.

96

**Role of the Gab1 / PI3K Complex in Secretion of Glycoprotein**

B. Shi, S. Ihara, Y. Fukui; Departmemt of Agricultural and Life Sciences, University of Tokyo, Tokyo, Japan

Signet ring cell carcinoma is one of poorly differentiated adenocarcinomas and characterized by loss of cell-cell interaction and enhanced secretion of glycoproteins, such as MUC1 and MUC4. In many of these cell lines, the ErbB2/ErbB3 complex is constitutively activated. Gab1 has been shown to be phosphorylated on tyrosine by the ErbB2/ErbB3 complex. We found that Gab1 is activated and bound to phosphoinositide 3-kinase (PI3K) in such a cell line, NUGC4. Treatment with an inhibitor for PI3K, LY294002, significantly suppressed the expression of glycoproteins on the cell surface in these cells. These results were also true in other signet ring cell carcinoma lines. Knockdown of Gab1 by RNAi suppressed the expression of glycoproteins on the cell surface. The glycoprotein was found inside the cells, suggesting that it is not production but is secretion, which is inhibited by knockdown of Gab1. Expression of a RNAi-resistant Gab1 restored the suppressed secretion of glycoproteins, confirming that the effect was indeed due to knockdown of Gab1. A mutant Gab1 incapable of binding to PI3K failed to release the suppression, suggesting that binding of Gab1 to PI3K is important for secretion of glycoproteins. These results suggest that Gab1 and PI3K may play crucial roles in regulating glycoprotein secretion.

97

**Effects Of $IP_3$ Receptor Kinetics and Intramembrane Diffusive Transport on Signal Localization and Amplification in Cerebellar Purkinje Cell Spines**

N. Hernjak, I. I. Moraru, J. C. Schaff, I. Novak, B. M. Slepchenko, F. Gao, L. M. Loew; Cell Biology, University Connecticut School of Medicine, Farmington, CT

Modeling and simulation of the calcium signaling events that precede long-term depression of synaptic activity in cerebellar Purkinje cells are performed using the Virtual Cell biological modeling framework (http://vcell.org/). It is found that the unusually high density and low sensitivity of inositol-1,4,5-trisphosphate ($IP_3$) receptors are critical to the ability of the cell to generate and localize a calcium spike in a single dendritic spine. The results also demonstrate the model's capability to simulate the supralinear calcium spike observed experimentally during coincident activation of the parallel and climbing fibers. The sensitivity of the calcium spikes to certain biological and geometrical effects is investigated as well as the mechanisms that underlie the cell's ability to generate the supralinear spike. The sensitivity of calcium release rates from the $IP_3$ receptor to calcium concentrations, as well as $IP_3$ concentrations, allows for the calcium spike to form. The diffusion barrier caused by the small radius of the spine neck is shown to be a functional switch, as a threshold radius is observed above which a spike cannot be formed. The calcium buffer capacity and diffusion rates from the spine also are critical in shaping the calcium spike. Additionally, detailed spatial simulations using the new lateral membrane diffusion capabilities in the Virtual Cell addressed the issue of phosphatidylinositol 4,5-bisphosphate resuply by signal amplification of lateral membrane diffusion versus activated local de novo synthesis. Supported by NIH P41-RR013186.

**A Modulatory Role for Phosphoinositide 3-Kinase in Gastric Parietal Cell Stimulation**

S. E. Mettler, S. Ghayouri, G. Patangay, J. G. Forte; Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA

The role of phosphoinositide 3-kinase (PI3K) in the stimulation of acid secretion by gastric parietal cells has been examined. Previous work has shown that histamine (H) stimulates glands ~3.5 fold over resting levels and histamine plus IBMX (H+I) stimulates glands ~8 fold over resting using the standard aminopyrine (AP) assay. Increased stimulation by IBMX has been attributed to inhibition of phosphodiesterase resulting in increased [cAMP]. Here, gastric glands were treated with H plus a common PI3K inhibitor, LY294002 (H+LY) producing a response similar to H+I with an AP accumulation ~7 fold greater than resting. Further examination showed that LY produced a biphasic response with maximal histamine enhancement at 40μM and inhibition of histamine stimulation at 80μM. This biphasic response was similar to wortmannin a PI3K inhibitor that enhances histamine stimulation at 100nM and inhibits at 10μM. Since PI3K is implicated in bulk endocytosis, relaxation of parietal cells via histamine H2 receptor antagonist (lupitidine) was tested. Secretion in response to H+LY slowed significantly after addition of lupitidine suggesting increased stimulation was not due to pumps remaining at the apical membrane, but that cells were stimulated to a higher degree. Stimulation by H+LY and H+I follow almost identical time course of AP accumulation over 30 min, whereas stimulation by H plateaus after the first 10 min. LY does not alter stimulation with carbachol or forskolin nor does it prevent inhibition caused by EGF. Thus, LY is not acting on

PI3K via the Ca2+/PKC pathway or the inhibitory EGF pathway and it must require activation of G protein-coupled H2 receptor prior to adenylate cyclase. We propose PI3K is activated during parietal cell stimulation via G protein-coupled H2 receptor and that PI3K modulates an inhibitory pathway that is overwhelmed by increased cAMP.

99

**hVps34 is a Nutrient-Regulated Lipid Kinase Required for Activation of p70 S6-Kinase by Insulin**

M. P. Byfield,[1] J. T. Murray,[2] J. M. Backer[1]; [1]Molecular Pharmacology, Albert Einstein College of Medicine, Bronx, NY, [2]MRC Protein Phosphorylation Unit, University of Dundee, Dundee, United Kingdom

Mammalian cells respond to nutrient deprivation by inhibiting energy consuming processes such as proliferation and protein synthesis, and by stimulating processes such as autophagy and transcriptional regulation of key metabolic genes. p70 S6-kinase (S6K1) is central to nutrient-responsive regulation of translation. S6K1 is activated by growth factors such as insulin and by mTOR, which is itself regulated by amino acids. While Class I PI 3-kinases play a well-recognized role in the regulation of S6K1, we now present evidence that the class III PI 3-kinase, hVps34, also regulates S6K1 as a critical component of the nutrient sensing apparatus. Overexpression of hVps34 or the associated hVps15 kinase activates S6K1, and insulin stimulation of S6K1 is blocked by microinjection of inhibitory anti-hVps34 antibodies, overexpression of a FYVE-domain construct that sequesters the hVps34 product PI[3]P, or siRNA-mediated knock-down of hVps34. hVps34 activity is not stimulated by insulin, and inhibition of hVps34 has no effect on phosphorylation of Akt or TSC2 in insulin-stimulated cells. This suggests that hVps34 is not part of the insulin-stimulated input to S6K1. However, hVps34 is inhibited by amino acid starvation, suggesting that it lies on the amino acid-regulated pathway to S6K1. hVps34 is also inhibited by glucose starvation and by activation of the AMP-activated Kinase (AMPK), which inhibits mTOR/S6K1 in glucose-starved cells. Our data suggest that hVps34 is a nutrient-regulated lipid kinase that integrates amino acid and glucose inputs to S6K1.

**Role of ZO-1 in Sphingosine-1-phosphate Receptor Regulated Endothelial Barrier Formation and Chemotaxis**

J. Lee,[1] E. Wang,[1] M. Lee[2]; [1]Gheens Center on Aging, University of Louisville Health Science Center, Louisville, KY, [2]Microbiology and Immunology, University of Louisville Health Science Center, Louisville, KY

Regulated barrier formation and chemotaxis are important functions of endothelial cells. Here, we show sphingosine-1-phosphate (S1P) by activating endothelial S1P1 receptor induce the translocation of ZO-1 to cellular migratory edges and tight-junctional structures. S1P-regulated ZO-1 translocation was inhibited by pertussis toxin, dominant-negative-Akt, -Cdc42, -Rac, -Rho, and T236A S1P1 receptor mutants, indicating S1P1-mediated signaling cascades are required. The full-length and C-terminal half of ZO-1, which contains cortactin binding site, were transfected into CHO cells and both polypeptides translocated to cellular cortical areas after S1P stimulation. In contrast, the N-terminal half of ZO-1, which fails to bind cortactin, was unable to translocate to cortical areas after S1P stimulation. Thus, the translocation of ZO-1 to cell migratory front may require cortactin association and ZO-1, a previously characterized component of tight junctions, may be critical in S1P-mediated chemotaxis. Likewise, S1P induced cortactin translocation to cellular migratory edges in a similar manner via Gi/ Akt/ Cdc42, Rho, and Rac pathway. Furthermore, double immunofluorescent staining showed both ZO-1 and cortactin were translocated to migratory edges, whereas only ZO-1 was present in endothelial tight junctions after S1P treatment. By Electric Cell-substrate Impedance Sensing technology, endothelial barrier integrity and wound-healing capability were enhanced following S1P stimulation. This enhanced barrier integrity and wound-healing capability was regulated by Gi/ Akt/ Cdc42, Rac, Rho pathway. Moreover, S1P-induced barrier integrity and wound-healing was significantly abrogated in S1P1 silenced endothelial cells. Together, these results suggest ZO-1 polypeptide may play critical roles in S1P-regulated barrier integrity and chemotaxis by the formation of two distinct ZO-1 functional complexes: ZO-1/ cortactin complexes that translocate to migratory edges to control endothelial chemotaxis and Junctional ZO-1 complexes that translocate to tight junctions to regulate endothelial barrier integrity.

**Small Molecule Probes of p90 Ribosomal Protein S6 Kinase Signaling**

M. S. Cohen, J. Taunton; Cellular and Molecular Pharmacology, University of California San Francisco, San Francisco, CA

p90 Ribosomal Protein S6 Kinases (RSKs) are ubiquitous downstream mediators of the Ras-mitogen-activated protein kinase (MAPK) pathway. In humans, there are four RSK isoforms (RSK1-4) of which RSK1 and RSK2 are the most extensively characterized. RSKs have been implicated in the regulation of diverse cellular processes including survival and proliferation; however, the physiological roles of RSKs remain poorly defined. Selective small molecule inhibitors of RSKs would be valuable tools to dissect their role in the MAPK pathway. We have recently described the design of a selective, irreversible small molecule inhibitor of RSK1 and RSK2 using a structural bioinformatics approach (Cohen et al. *Science* **308**, 1318). This inhibitor contains an electrophilic fluoromethylketone group that covalently modifies a non-conserved cysteine residue in the kinase active site. To explore structure-activity relationships, we synthesized a series of analogs containing various electrophilic groups. A vinyl ketone analog was identified that exhibited increased cellular potency relative to the fluoromethylketone inhibitor. We are currently using these inhibitors to probe the physiological roles of RSK in a variety of cellular contexts.

102

**The Evolutionary Origins of Phosphorylation**

Z. Serber,[1] S. M. Pearlman,[2] J. E. Ferrell[1]; [1]Molecular Pharmacology, Stanford University Medical School, Stanford, CA, [2]Computer Science, Stanford University, Stanford, CA

Life employs protein phosphorylation as a general mechanism to regulate the temporal and spatial activation of a huge variety of cellular processes. Eighteen years ago molecular biologists first realized that they can sometimes reconstitute the constitutively phosphorylated state of a protein by substituting an acidic residue, either aspartate or glutamate, for the phosphosite, a seemingly fortuitous trick that works despite differences in the side chain geometry and charge[1]. Here, we demonstrate that nature has been employing the same 'trick' for far longer, evolving some genes to encode an acidic residue, where once there was a phosphosite and vice versa. Furthermore, our analysis suggests that phosphorylation may have first evolved to reversibly mimic glutamate in crucial locations and conferred an advantage by making a protein, previously regulated only by

synthesis and destruction, into one switchable by a fast, reversible enzymatic reaction. 1. Thorsness, P. E. and Koshland, D. E., Jr.. Inactivation of isocitrate dehydrogenase by phosphorylation is mediated by the negative charge of the phosphate. J Biol Chem 262: 10422-5.

103

**Predicted Influence of Cell Size and Shape on Global and Local Phosphorylation Levels**

D. J. Odde, J. Meyers, J. Craig; Biomedical Engineering, University of Minnesota, Minneapolis, MN

In the analysis of cell signaling the three-dimensional spatial dependence of the signal is often ignored. For example, in the case of second messengers that are generated at the plasma membrane and then diffuse in the cytoplasm to reach their targets, the second messengers are considered to have a concentration that varies only in time, and not in space. Here we use mathematical modeling of a plasma membrane-bound kinase and a cytoplasmic phosphatase to show that as a model cell grows, the substrate becomes progressively dephosphorylated due to decreased proximity of the substrate to the kinase. Conversely, as a cell flattens at constant volume, the substrate becomes phosphorylated. Also, in the leading edge of polarized cells and in protrusions such as filopodia, the substrate is highly phosphorylated relative to the bulk cytoplasm. The results demonstrate that phosphorylation can be stimulated, both globally and locally, via changes in cell size and shape. Finally, the principles apply similarly to other antagonistic systems, such as spatially segregated GEF/GAP pairs acting on G-proteins. The predicted consequence of these results is that kinase-mediated (or GEF-mediated) signaling can be turned on and off locally and globally simply by changes in cell size and shape as mediated by cytoskeletal rearrangement. The modeling predicts that cells that are well-spread on a two-dimensional surface will have a phosphorylation state different from a less-spread cell that is in a three-dimensional matrix, independent of the molar concentration of the extracellular stimulus or its downstream kinase/phosphatase and/or GEF/GAP transducers.

104

**The Role of ARNO/cytohesin-2 in $A_{2A}$-Adenosine Receptor Signaling**

I. Gsandtner, C. Charalambous, F. Eskandary, H. Farhan, M. Freissmuth, J. Zezula; Center of Biomolecular Medicine and Pharmacology, Medical University of Vienna, Institute of Pharmacology, Vienna, Austria

Recent findings suggested the existence of G-protein independent signaling pathways for the $A_{2A}$-adenosine receptor. To find interaction partners necessary for signaling, we have used the intracellular carboxyl terminal tail of the $A_{2A}$-receptor as bait in a yeast-two hybrid interaction screen. One of the interacting proteins identified as ARNO/cytohesin-2. ARNO/cytohesin-2 was discovered as a nucleotide exchange factor for the small (monomeric) G proteins of the ADP-ribosylation factor (ARF) family, (while ARFs were originally identified as cofactors for cholera toxin-mediated ADP-ribosylation of $G_s$). Mutation of the $A_{2A}$-receptors C-terminal tail revealed that a minimum requirement supporting the interaction is met by the first 22 amino acids adjacent to the seventh trans-membrane region. The direct interaction found in the yeast-two hybrid system was further confirmed by mutual pull-down (of fusion proteins expressed in bacteria) and coimmunoprecipitation of the proteins expressed in mammalian cells. ARNO/cytohesin-2 had no effect on cAMP accumulation after stimulation with an $A_{2A}$-specific agonist. However, the presence of ARNO is required to support the alternative ($G_s$ -independent) signaling to mitogen-activated protein kinase, because a dominant negative version of ARNO/cytohesin-2 efficiently suppresses the sustained phase of receptor dependent MAP-kinase phosphorylation. Since treatment with Brefeldin A did not influence ERK1/2 activation we concluded that this pathway is rather dependent on Arf6 than on Arf1 or Arf3. To prove this we transfected cells with a plasmid encoding the dominant negative version of Arf6 and found an impaired second phase of ERK1/2 phosphorylation. These experiments suggest that ARNO/cytohesin-2 interacts directly with the $A_{2A}$-adenosine receptor. This interaction regulates $A_{2A}$-adenosine receptor mediated MAP-kinase via Arf6.

## Mitosis & Meiosis I (105-129)

105

**Ran Coordinates pre- and post-Metaphase Events in *Drosophila* Embryos by Regulating the Localization of Aurora A kinase and Mitotic Kinesins KLP61F and KLP3A**

R. V. Silverman-Gavrila, A. Wilde; Medical Genetics and Microbiology, University of Toronto, Toronto, ON, Canada

Previously we showed that a balance of RanGDP/GTP is required for spindle assembly and function in syncytial *Drosophila* embryos. Ran GTP was required for mitotic events such as microtubule nucleation, centrosome duplication, division spindle and midbody assembly and stability, nuclear division, chromosome alignment at metaphase plate, anaphase chromosome movement, and skeletor spindle matrix organization. One molecular mechanism by which Ran regulated these mitotic events *in vivo* was the re-localization of the kinase Aurora A from centrosomes to spindle microtubules. The phenotypes induced by altered levels of RanGTP were consistent with Ran regulating the activity of motor proteins involved in spindle organization. Indeed we showed that Ran coordinates the localization of mitotic kinesins KLP61F and KLP3A. Injection of anti-Aurora A kinase antibody or Aurora A kinase inhibitors into *Drosophila* embryos caused spindle assembly and chromosome division defects that were a subset of the defects seen after perturbation of Ran pathway as well as mislocalization of KLP61F and KLP3A. Certain spindle phenotypes were seen with a higher frequency after Aurora A inhibition than after Ran pathway disruption suggesting that Aurora A activity is regulated by more than one mechanism.

106

**Analysis of a RanGTP-regulated Gradient Essential for Mitosis in Somatic Cells**

P. Kalab, A. Pralle, R. Heald, K. Weis; Molecular and Cell Biology, UC Berkeley, Berkeley, CA

The small GTPase Ran regulates interactions between nuclear transport receptors of the importin β family and cargoes. Although Ran-regulated importin β cargoes were shown to function during spindle assembly in *Xenopus* egg extracts, the role of this pathway during mitosis in somatic cells is unclear. We have examined the spatial organization of the Ran-importin β system in live cells by conventional and fluorescence lifetime microscopy (FLIM) using a model cargo, termed Rango, that increases its fluorescence resonance energy transfer (FRET) signal when released from importin β by RanGTP. While Rango release by RanGTP occurs in nuclei during interphase, Rango is predominantly free upon nuclear envelope breakdown in mitotic cells. However, the concentration of free Rango is further elevated around mitotic chromatin. *In vitro* experiments

and modeling indicate that this corresponds to a localized increase in RanGTP concentration sufficient to induce microtubule polymerization. Ablation of this cargo gradient in cells leads to defects in spindle assembly. Our analysis reveals that the Ran-importin β pathway is sensitive to small concentration differences, allowing it to locally activate essential mitotic targets in a switch-like fashion.

107

**A High-throughput Screen for Small Molecules that Disrupt the Interaction Between RanGTP and Importin-beta**

J. F. Soderholm,[1] M. Uehara-Bingen,[2] B. Wolff,[2] J. Williams,[2] K. Weis,[1] R. Heald[1]; [1]Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA, [2]Pharmaceutical Chemistry, University of California, San Francisco, San Francisco, CA

The Ran GTPase regulates nucleocytoplasmic transport and mitotic progression through its interaction with the transport receptor importin-β. It has been hypothesized that a RanGTP gradient regulates mitotic events by releasing importin-β-bound mitotic factors in a spatially-restricted manner around the chromosomes. A direct test of this hypothesis in living cells would be feasible with a rapidly-acting small molecule inhibitor that blocks the interaction between RanGTP and importin-β. An inhibitor of this type could be used to assess the roles of proteins at specific stages of mitosis, such as spindle assembly and nuclear envelope assembly. We have designed a high-throughput, 384-well format screen to identify such compounds using a fluorescence resonance energy transfer (FRET)-based assay. Our assay includes a CFP-tagged version of Ran (the FRET donor) and a YFP-tagged version of importin-β (the FRET acceptor). When CFP-RanGTP binds to YFP-importin-β energy is transferred from CFP to YFP, leading to FRET. Our screen was designed to identify compounds that reduce FRET by disrupting the interaction between the probes. A critical component of our screen is a computer program that we wrote using Perl to manage the large volume of data generated. The program parses the data and uses it to generate color-coded “heat maps” that indicate changes in donor and acceptor emission intensities for each assay plate. The program also identifies false positives resulting from fluorescent compound interference, and generates a list of potential “real hits” that includes chemical structures. In a primary screen of 137,284 compounds, we have identified approximately 100 non-interfering compounds that interrupt the FRET signal generated by our probes. By integrating our simple fluorescence-based assay with automated data analysis, we have developed an efficient method for identifying compounds that disrupt the RanGTP/importin-β interaction.

108

**Does Nanoscale Electrostatics Move Chromosomes During Mitosis?**

L. J. Gagliardi; Physics, Rutgers University, Camden, NJ

Identifying the motive force is central to explaining chromosome motions during mitosis. Presently, there is no consensus on what it is. I have proposed a minimal assumptions comprehensive model for post-attachment chromosome motions based on nanoscale electrostatics and assumptions regarding the net charge on kinetochores and centrosomes [1,2]. The present work shows that given the electric dipole nature of tubulin and the dynamic instability of microtubules it is possible to account for prometaphase post-attachment, metaphase, and anaphase chromosome motions within a comprehensive model based on nanoscale electrostatics without any assumptions regarding the net charge of kinetochores and centrosomes. Microtubule subunits are electric dipolar structures that can act as intermediaries extending the reach of the electrostatic interaction in spite of counterion screening. This allows prometaphase post-attachment and metaphase chromosome motions to be explained by statistical fluctuations in nanoscale electrostatic antipoleward microtubule assembly forces acting at chromosome arms, kinetochores, and poles, combined with similar fluctuations in nanoscale electrostatic microtubule poleward-directed disassembly forces acting at kinetochores and spindle poles. After a bivalent attachment has been completed the "inverse square" dependence of the electrostatic antipoleward force acting at chromosome arms ensures congressional motion of chromatid pairs to the midcell region. Stable metaphase mid-cell oscillatory motion is a direct consequence of the inverse square dependence of the antipoleward forces. With the increase in free calcium concentration at the onset of anaphase, the probability for microtubule assembly is decreased significantly, allowing electrostatic microtubule disassembly forces acting at kinetochores and poles to dominate, and anaphase-A motion ensues. Anaphase-B cell elongation is addressed consistently by electrostatic repulsion between the charged free ends of polar microtubules originating from opposite poles as they disassemble. [1] L. John Gagliardi, Phys. Rev. E 66, 011901 (2002). [2] L. John Gagliardi, J. Electrostat. 63, 309-327 (2005).

**Biophysical Properties Governing Nuclear Shape and Size of Mitotic Fission Yeast**

G. Lim,[1] Y. Torii,[1] G. Huber,[2] J. Miller,[1] S. Sazer[1]; [1]Department of Biochemistry and Molecular Biology, Baylor College of Medicine, Houston, TX, [2]Department of Cell Biology, University of Connecticut Health Center, Farmington, CT

In mitosis of the fission yeast *Schizosaccharomyces pombe*, a mitotic spindle forms and elongates within the nucleus, driving the nucleus to undergo a sequence of shape transformations (round -> oblong -> peanut -> dumbbell) before it resolves into two round daughter nuclei. The combined volume of the daughter nuclei immediately after mitosis is the same as the volume of the single nucleus at the onset of mitosis (Torii and Sazer, unpublished); consequently, the area of the nuclear envelope (NE) must increase by 26% during this process. We aim to determine the biophysical properties governing these shape and size changes. To that end, we have developed a physical model of the fission yeast nucleus. It is based on current understanding of the nuclear architecture, insight from experimental images of wild-type and mutant nuclei, and concepts from the membrane mechanics governing red blood cell shape, vesicle shape, and tube formation from bilayer membranes. The model incorporates NE bending elasticity, regulation of the NE area, nuclear lumen and nucleoplasmic volumes, and spindle elongation, as well as excluded-volume effects of the condensed chromosomes, nucleolus, and mitotic spindle. In relation to regulation of the nucleoplasmic volume, the model predicts a finite nucleoplasmic pressure. The model yields quantitative estimates (as ratios to the NE bending stiffness) of the NE membrane tension, nucleoplasmic pressure, and spindle-pushing force. More generally, the model should be useful for explaining various abnormal nuclear shapes in terms of biophysical defects.

**The Cell Cycle as a Finite State Machine**

J. W. Jacobberger,[1] R. M. Sramkoski,[1] D. V. Soni,[2] P. S. Frisa[1]; [1]Cancer Center, Case Western Reserve University, Cleveland, OH, [2]Environmental Health Sciences, Case Western Reserve University, Cleveland, OH

Division of centrosomes, chromatin, and the cell are morphological periodicities with sharply defined boundaries. DNA synthesis defines a biochemical periodicity. These periodicities imply underlying regulatory logic that is periodic. Regulatory biochemical activities are also periodic, however the boundaries are not usually sharply defined. Periodic synthesis and degradation of the cyclins might be described as prototype markers of biochemical periodic phenomena that are surrogates for biochemical switches. This is because (1) the activities of the cognate Cdks increase as a function of cyclin quantity; (2) different cyclins are synthesized periodically and sequentially, and (3) the periodic activities regulate down-stream cell cycle phase transitions. Pines and Rieder (Nature Cell Biol., 2001, 3:E3-E6) put forward the idea that mitosis can be described or viewed as transition states defined by levels of biochemical activities rather than morphology. They describe 5 transition states defined by dominant roles for Cyclin A/CDK, polo-like kinases, aurora B kinase; Cyclin B/Cdk1; APC-Cdc20, BubR1/Mad2; fully active APC-Cdc20; and APC-Cdh1. This constitutes a biochemical finite state model in which states are marked by specific biochemical activities. We report here that this model is supported in principal by correlated single cell measurements of some of these activities. We have measured the levels of substrates for Aurora Kinase B, Cyclin B1/Cdk1, APC/Cdc20, and fully active APC/Cdc20-APC/Cdh1 by multiparameter cytometry. The correlated measurements produce clusters that can be thought of as vectors (the data have magnitude and direction) and can be defined objectively by multi-dimensional geometric boundaries. These clusters define finite biochemical states. This approach leads to a view of the cell cycle as a biochemical finite state machine. We hypothesize that this logic can be extended from mitosis to the entire cell cycle.

**Ancestral Mitotic Mechanisms in the Basal Eukaryote, *Giardia lamblia***

M. S. Sagolla, S. C. Dawson, W. Z. Cande; Molecular and Cell Biology, UC Berkeley, Berkeley, CA

*Giardia lamblia*, a binucleate parasite, belongs to the earliest diverging eukaryotic lineage, the Diplomonads. *Giardia* is characterized by two diploid nuclei and a complex microtubule cytoskeleton with eight flagella. During prophase both nuclei migrate to the center of the cell while two independent bipolar spindles assemble around each nucleus. The spindles elongate to segregate daughter nuclei along the left-right axis of the cell. Transmission electron microscopy (TEM) confirmed that mitosis is semi-open, the spindle is extra-nuclear and microtubules nucleated at basal bodies enter the nucleus through openings in the nuclear membrane at each pole. The *Giardia* homolog of the centromere specific histone, CENP-A, localized to a discreet spot on each chromosome. During mitosis CENP-A localization showed a distinct anaphase a and b and chromosome segregation based on microtubule-kinetochore interactions. Treating cells with the microtubule-stabilizing drug taxol or the destabilizing drug nocodazole disrupted the integrity of the mitotic spindles and resulted in chromosome segregation defects confirming the role of microtubules in chromosome segregation. We previously showed that the flagella are present throughout mitosis and are segregated to the sides of the central mitotic nuclei. We show the conserved basal body/centriole protein centrin localized to the flagellar basal bodies during interphase and the spindle poles during mitosis, confirming our TEM images of basal bodies at the spindle poles. The localization pattern of centrin during spindle assembly is consistent with a role for flagellar basal bodies in spindle nucleation and organization. Following spindle breakdown in late telophase centrin localized to the flagellar basal bodies between the new nuclei. In order to determine the pattern of nuclear inheritance and flagellar segregation we used video microscopy of living cells to follow the migration of the nuclei and flagella during mitosis.

112

**A Mammalian Somatic Cell-Based in vitro System for Studying Mitotic Protein Turnover**

M. K. Summers, P. K. Jackson; Pathology, Stanford University, Stanford, CA

Proper execution of mitosis requires the ordered proteolysis of mitotic regulators, catalyzed by the Anaphase Promoting Complex (APC), an E3 ubiquitin ligase. Despite intense study, the mechanism(s) contributing to the timely destruction of APC substrates, for example, the differential kinetics of cyclins A and B destruction, is poorly understood. The *Xenopus* egg extract system has been a powerful tool for studying the basic mechanisms controlling ubiquitination of cyclins and other mitotic regulators by the APC and their linked destruction. However, this system does not fully recapitulate important aspects of the mitotic regulation in the somatic cell cycle, e.g. spindle checkpoint activity. Furthermore, the system is not amenable to powerful siRNA techniques and genomic data available in the human system, which together would greatly enhance our ability to identify new factors and to manipulate the system. To this end, we have established a mammalian somatic cell-based extract system for the study of mitotic destruction events. This system is competent for both ubiquitination and destruction of mitotic proteins, including cyclin A and securin. We have validated critical biochemical requirements in this system including ATP dependence (by treatment with apyrase), proteasome dependence (by treatment with MG132), and APC dependence by blocking ubiquitination with the APC inhibitor Emi1. Using this system we find that both spindle checkpoint components additional control steps at the post-ubiquitination level contribute to the timing of cyclin destruction. The results of these studies will be presented.

113

**The Mitotic Spindle Protein Astrin is a Substrate of the CDC14A Phosphatase**

M. V. Nachury,[1] B. K. Kaiser,[1] G. Mack,[2] D. Compton,[2] P. K. Jackson[1]; [1]Department of Pathology, Stanford University, Stanford, CA, [2]Department of Biochemistry, Dartmouth Medical School, Hanover, NH

In addition to being a core component of the centrosome, the human CDC14A phosphatase is a regulator of mitosis. However, very few validated substrates of CDC14A have been identified thus far. A 2-hybrid screen for partners of CDC14A identified the microtubule associated protein astrin. Since astrin is phosphorylated in mitosis and it localizes to the mitotic spindle, we set out to characterize the astrin/CDC14A interaction. First, astrin interacts with CDC14A in in vitro association assays. Secondly, CDC14A is able to partially dephosphorylate astrin. Thirdly, astrin protein levels reach a peak in mitosis and rapidly decline after mitotic exit in a proteasome-dependent manner. Finally, depletion of astrin from cultured cells results in a significant mitotic exit delay. We are currently following preliminary results showing that astrin associates with the dynein/dynactin complex in a phosphorylation-dependent manner. Together with recent identification of MKLP1 as a substrate of CDC14A, this study will shed light on the regulation of mitosis by the CDC14A phosphatase.

114

**Efficient Mitosis in Human Cells Lacking Poleward Microtubule Flux**

N. J. Ganem, K. S. Upton, D. A. Compton; Biochemistry, Dartmouth Medical School, Hanover, NH

Chromosome segregation relies on the dynamic properties of spindle microtubules (MTs). Poleward MT flux contributes to spindle microtubule dynamics through the disassembly of microtubule minus ends at spindle poles coupled to the continuous poleward transport of spindle microtubules. Despite being conserved in metazoan cells, the function of flux remains controversial because flux rates differ widely in different cell types. For example, in meiotic systems, flux is relatively fast and nearly equivalent to the rate of chromosome movement. In contrast, flux is relatively slow in mitotic systems and significantly slower than chromosome movement. Here, we show that human mitotic cells depleted of the kinesin-13 proteins Kif2a and MCAK display high frequencies of lagging chromatids at anaphase and the spindles lack detectable flux. Elimination of flux reduces poleward chromosome velocity ~20%, but does not hinder bipolar spindle assembly, chromosome alignment or mitotic progression. These data demonstrate that mitosis proceeds efficiently in human cells without detectable poleward microtubule flux, and that kinetochores are sufficient to effectively power chromosome movement. We speculate that the selective pressure to maintain flux in cells where it contributes little to chromosome movement derives from the role it plays in regulating kinetochore activity and/or providing plasticity to microtubule attachment at kinetochores and spindle poles.

115

**Chemical Biology of Cell Division: New Probes for Monopolar Mitoses**

U. Peters, J. Cherian, J. H. Kim, B. H. Kwok, T. M. Kapoor; Chemistry and Cell Biology, Rockefeller University, New York, NY

To identify small molecules that affect a cellular process in different ways, it is not known whether a screen with unrelated compounds spanning a vast region of chemical space, or with compounds related to a 'privileged scaffold' focused on a small region of chemical space, is needed. To test the latter possibility, we synthesized a collection of ~100 compounds based on a diaminopyrimidine scaffold, a motif common in ATPase and kinase inhibitors. We carried out a microscopy-based screen examining the dose-dependent effects of these compounds on mammalian mitosis. Monopolar and multipolar spindles, bipolar spindles with disorganized microtubules or unaligned chromosomes, and chromosome segregation defects were observed. The number of phenotypes in this chemical screen was comparable to that observed in RNAi-based genome-wide screens. Our studies on the mechanism of action of these compounds started with those that resulted in monopolar mitoses. In vitro assays with recombinant Eg5, a kinesin required for bipolar spindle assembly, excluded it as a direct target of these compounds. Analyses of RNAi-phenotypes for mitotic kinases suggested that polo-like kinase 1 (Plk1) may be a possible target. Kinase assays confirmed that one compound, named DAP-81, inhibits Plk1 (IC50~1μM). In another recent study, compounds closely related to DAP-81 have also been reported to inhibit Plk1 in vitro. We show that DAP-81 inhibits the phosphorylation of Plk1 substrates in cells at concentrations where the phosphorylation of aurora kinase substrates was unchanged. As normal bipolar spindles do not form after Plk1 RNAi, DAP-81 provided a tool to examine Plk1 function in assembled bipolar spindles. We find that Plk1 contributes to chromosome-microtubule interactions and to the maintenance of normal bipolar spindles. Structurally unrelated chemical inhibitors of Plk1 were used in parallel experiments to confirm the results obtained with DAP-81.

116

**A Catalytic Subunit of Phosphatase 2A(PP2A) Modulates Pulling Forces During Asymmetric Division of One-cell Stage *C elegans* Embryos**

K. Afshar, P. Gönczy; ISREC/EPFL, Epalinges, Switzerland

In one-cell stage *C. elegans* embryos, asymmetric positioning of spindle is achieved by an imbalance of pulling forces on spindle poles, with more force pulling on the posterior spindle pole (Grill et al, 2002). Heterotrimeric G proteins are essential for this process, as simultaneous inactivation of two Galpha subunits, GOA-1 and GPA-16, as well as that of their positive regulator GPR-1/2, results in extreme reduction of pulling forces and symmetric division (Colombo et al, 2003). How these proteins are modulated to ensure accurate force generation remains incompletely understood. We identified a catalytic subunit of PP2A (hereafter refered to as PP2A) as a novel modulator of pulling forces. Inactivation of PP2A results in reduced pulling forces on both spindle poles. Nevertheless, imbalance of pulling forces is retained and the first division is asymmetric. Immunolocalization studies reveal that PP2A is mainly cytoplasmic but also localizes to centrosomes. We found that PP2A physically interacts with GPR-1/2 in yeast two hybrid assay and in co-immunoprecipitation experiments. In addition, we found that PP2A is required for efficient interaction of GPR-1/2 with both GOA-1 and GPA-16. Accordingly, the phenotypes of *goa-1* and *gpa-16* mutant embryos are enhanced upon inactivation of PP2A in addition. Importantly, we detected two GPR-1/2 species by 2D gel analysis, one of which is diminished relative to the other upon inactivation of PP2A. Together, our results indicate that dephosphorylation of GPR-1/2 by PP2A is necessary for accurate generation of pulling forces during asymmetric spindle positioning.

117

**The Role of Vertebrate Cohesin in Mitotic Spindle Formation**

X. Kong,[1] E. Sonoda,[2] S. Takeda,[2] K. Yokomori[1]; [1]Biological Chemistry, University of California, Irvine, Irvine, CA, [2]Kyoto University, Kyoto, Japan

Cohesin is an essential protein complex required for sister chromatid cohesion. Cohesin associates with chromosomes and establishes sister chromatid cohesion during interphase. During metaphase, only a small amount of cohesin remains at the chromosome-pairing domain, while the majority of cohesin resides in the cytoplasm. The significance of the cytoplasmic cohesin was unclear. We describe the mitosis-specific recruitment of cohesin to the spindle poles through its association with centrosomes and interaction with NuMA. Cohesin depletion abolished mitotic spindle aster assembly in vitro, which was rescued by mitotic, but not S phase nuclear, cohesin, indicating the mitosis-specific function of cohesin in spindle assembly. Depletion of cohesin using siRNAs in human cells and conditional knockout in chicken DT40 cells resulted in abnormal mitotic spindle assembly in vivo. These results identify a novel spindle-associated role for vertebrate cohesin during mitosis, in addition to its function in sister chromatid cohesion.

118

**Development of X tropicalis Egg Extracts as a Model System: Insights into Spindle Length Regulation**

T. J. Maresca, M. D. Blower, K. S. Brown, T. C. Grammer, R. M. Harland, R. Heald; Molecular and Cell Biology, UC-Berkeley, Berkeley, CA

The biochemical and cytological accessibility of the *Xenopus laevis* egg extract system has been instrumental in studies of fundamental cellular processes occurring throughout the cell cycle, including DNA replication, nucleocytoplasmic transport, chromosome condensation and spindle assembly. However, a deficiency of sequence data and its pseudotetraploid genome has limited the use of *X. laevis* for genetic and proteomic approaches. The related frog *Xenopus tropicalis* has emerged as an organism that expands the range of possible experiments. *X. tropicalis* are smaller, diploid, and have a shorter generation time, making them more amenable to genetics. Extensive genome sequence data are available for *X. tropicalis*, facilitating rapid protein identification by mass spectrometry, and the development of specific chromosome probes. To test whether the smaller *X. tropicalis* eggs could also be utilized for in vitro experiments, we prepared cytoplasmic extracts and tested them in several assays. As for *X. laevis*, *X. tropicalis* extracts could induce *X. laevis* sperm nuclei to transit through the cell cycle, inducing nuclear envelope assembly during interphase, and spindle assembly during metaphase. *X. laevis* antibodies revealed similar staining patterns on *X. tropicalis* spindles by immunofluorescence, and recognized homologous proteins as determined by Western blot or immunoprecipitation and mass spectrometry analysis. Whereas *X. laevis* extracts contained multiple variants of most proteins, all *X. tropicalis* extracts proteins examined existed as single isoforms, reflecting the difference in ploidy of the two species. Interestingly, *X. tropicalis* spindles were ~30% smaller than *X. laevis* spindles. We are currently investigating how cytoplasmic activities contained within each extract define spindle length. Thus, in addition expanding the possible range of experiments, the use of *X. tropicalis* may provide novel insight into spindle morphogenesis.

119

**Three Human Kinesin-8 Family Members, Kif18A, Kif18bB and Kif19, Perform Distinct Roles in Mitosis**

T. M. Sonbuchner, D. W. Buster, D. J. Sharp; Physiology and Biophysics, Albert Einstein College of Medecine, Bronx, NY

Kinesins are mechanochemical proteins that use ATP to power multiple cellular processes (including transport and mitosis) while binding microtubules (MT). Recently Kinesin-13's (kinesins with internal motor domains) have received notice because of their seemingly unique ability to depolymerize MTs. However, another class of kinesins, termed Kinesin-8s, has been found to have this same property. Using a human osteosarcoma cell line (U2OS) we have cloned the three human Kin-8's, termed Kif18A, Kif18B, and Kif19. Using siRNA to suppress the expression of each, we have found that all three significantly impact mitosis. Interestingly, real time imaging indicates distinct impacts on spindle and chromosome dynamics. Thus, humans have three Kinesin-8 family members with important and distinct roles in mitosis.

120

**Distinct Roles for Three Kinesin-13 Proteins During Mitosis in Human Cells**

N. J. Ganem, D. A. Compton; Biochemistry, Dartmouth Medical School, Hanover, NH

Kinesin-13 family members are characterized as having an internal catalytic motor domain known to induce microtubule depolymerization. The human genome encodes three distinct Kinesin-13 family members, Kif2a, Kif2b, and MCAK (Kif2c). MCAK localizes to kinetochores and spindle poles and is essential for correction of improper attachment of microtubules to kinetochores. MCAK deficiency does not alter bipolar spindle assembly or chromosome movement, but increases the frequency of lagging chromatids at anaphase. Kif2a is essential for bipolar spindle assembly. It localizes predominantly to spindle poles where it induces disassembly of microtubule minus ends needed for poleward microtubule flux. Here, we examine the mitotic role of Kif2b, the third member of the Kinesin-13 family in humans. Following knock-down of Kif2b using siRNA, we observe that a majority of cells assemble abnormal spindles with highly disorganized microtubules. Chromosomes in these cells do not display typical oscillatory motion and the velocity of movement is severely depressed. In the minority of cells that build bipolar spindles following Kif2b siRNA treatment, chromosomes align and segregate at anaphase, but cytokinesis fails and the cleavage furrows regress leading to binucleate cells. These data demonstrate that Kif2b is important for mitotic spindle assembly, chromosome movement, and completion of cytokinesis, and indicate that each of the Kinesin-13 family members play functionally distinct roles during mitosis in human cells.

121

**Myosin Phosphatase Targeting Subunit1 Controls Sister Chromatid Segregation by Phosphorylation-dependent Association with Polo-like Kinase1**

S. Yamashiro,[1] Y. Yamakita,[1] G. Totsukawa,[1] H. Goto,[1] K. Kaibuchi,[2] M. Ito,[3] D. Hartshorne,[4] F. Matsumura[1]; [1]Mol. Biol. & Biochem., Rutgers, Piscataway, NJ, [2]Cell Pharmacology, Nagoya University, Nagoya, Japan, [3]Internal Medicine, Mie University, Tsu, Japan, [4]Nutritional Sciences, University of Arizona, Tucson, AZ

The protein phosphatase 1 (PP1C) catalytic subunit forms a complex with a variety of regulatory molecules (phosphatase targeting subunits), which converts PP1C into many forms of phosphatase with distinct substrate specificities. One of such targeting molecules is the myosin phosphatase targeting subunit1 (MYPT1). MYPT1, when complexed with PP1C, can effectively dephosphorylate several substrates including myosin light chain, moesin and adducin, and, therefore is believed to control microfilament organization. Surprisingly, we have found that MYPT1 controls sister chromatid segregation by its association with polo-like kinase1 (PLK1), the molecule of which is known to regulate a variety of mitotic events including chromosome segregation. MYPT1 was phosphorylated by cdc2 kinase in a mitosis-specific way, and the phosphorylation sites are well conserved among vertebrate MYPT1. Interestingly, one (Ser473) of these sites constitutes a motif (Ser-phosphoSer-Pro) for phosphorylation-dependent binding to the polo-box domain of PLK1. Indeed, MYPT1 and PLK1 co-immunoprecipitated as a complex. GST pull-down assays confirmed that MYPT1, when phosphorylated by cdc2, directly bound to PLK1. MYPT1 depletion by siRNA in HeLa and SW962 cells resulted in mitotic arrest. Giemsa staining of mitotic chromosome spreads demonstrated that cohesion of sister chromatids at the centromere was disrupted in MYPT1-depleted cells whereas control chromosome retained tight association of sister chromatids at the centromere. An antibody specific to Ser473-phosphorylated MYPT1 revealed that phosphorylated MYPT1 co-localized with PLK1 at the kinetochores. Depletion of PLK1 disrupts the kinetochore localization of MYPT1, indicating that MYPT1's localization at the kinetochore depends on PLK1. PLK1 is reported to facilitate chromosome segregation by phosphorylating components of the cohesin complex. Our results thus suggest that the MYPT1/PP1C complex is a phosphatase that counteracts PLK1, preventing premature sister chromatid segregation before metaphase-anaphase transition.

122

**The C elegans Tousled-like Kinase TLK-1 Contributes to Mitotic Chromosome Segregation as a Substrate and Regulator of the Aurora B Kinase AIR-2**

Z. Han,[1] G. M. Riefler,[1] J. R. Saam,[2] S. E. Mango,[2] J. M. Schumacher[1]; [1]Molecular Genetics, University of Texas MD Anderson Cancer Center, Houston, TX, [2]University of Utah Huntsman Cancer Institute, Salt Lake City, UT

The Aurora kinases control multiple mitotic processes including centrosome maturation, spindle assembly, chromosome segregation, and cytokinesis. Aurora activity is regulated in part by a subset of Aurora substrates that once phosphorylated, can enhance Aurora kinase activity. Aurora A substrate activators include TPX2 and Ajuba, while the only known Aurora B substrate activator is the chromosomal passenger INCENP. We report that the C. elegans Tousled kinase TLK-1 is a second substrate activator of the Aurora B kinase AIR-2. Tousled kinase (Tlk) expression and activity have been linked to ongoing DNA replication and Tlk can phosphorylate the chromatin assembly factor Asf. We found that TLK-1 is phosphorylated by AIR-2 during prophase/prometaphase, and that phosphorylation increases TLK-1 kinase activity in vitro. Phosphorylated TLK-1 increases AIR-2 kinase activity in a manner that is independent of TLK-1 kinase activity but depends on the presence of ICP-1/INCENP. In vivo, TLK-1 and AIR-2 genetically cooperate to ensure proper mitotic chromosome segregation. These results suggest that Tousled kinases have a previously unrecognized role in mitosis and that Aurora B associates with discrete regulatory complexes that may impart distinct substrate specificities and functions to the Aurora B kinase.

123

**TD-60, a Putative Guanine Exchange Factor, Regulates Chromosome Congression and Cytokinesis by Controlling Aurora B Kinase Activity**

S. E. Rosasco, W. Lan, P. T. Stukenberg; Biochemistry and Molecular Genetics, University of Virginia, Charlottesville, VA

Aurora B is a mitotic serine/threonine kinase involved in the regulation of kinetochore-microtubule attachment and the positioning of the cytokinetic furrow. It exists in a complex with the passenger proteins INCENP, Survivin and Borealin/Dasra during mitosis. TD-60 is a putative guanine exchange factor (GEF) that has also been identified as a mitotic passenger protein. We have shown that embryos injected with TD-60 antibodies exhibit a failure to undergo cytokinesis, and extracts depleted of TD-60 fail to align chromosomes; two phenotypes consistent with misregulation of Aurora B kinase activity. TD-60 physically interacts with a select population of the Aurora B complex in *Xenopus* embryonic extracts. In both extracts and in vitro, TD-60 regulates Aurora B kinase activity by controlling phosphorylation on the key regulatory residue S850 of INCENP by Aurora B. TD-60 also interacts with PP1 and controls the interaction of PP1 with the Aurora B complex. We propose that TD-60 regulates PP1 to modulate Aurora B kinase activity during mitosis.

124

**Inhibition of Polo-like Kinase 1 by Antibody Microinjection Inhibits the Mitotic Spindle Checkpoint and Causes Aberrant Mitotic Exit**

J. R. Daum,[1] W. Lan,[2] P. Stukenberg,[2] G. J. Gorbsky[1]; [1]Molecular, Cell, and Developmental Biology, OMRF, Oklahoma City, OK, [2]Department of Biochemistry and Molecular Genetics, University of Virginia Medical School, Charlottesville, VA

Polo-like kinase-1 (Plk1) is an evolutionarily conserved serine/threonine protein kinase. Its activities influence the assembly and function of the mitotic spindle, mitotic checkpoint signaling, chromosome segregation, and cytokinesis. We have previously demonstrated that Plk1 is the kinase responsible for creation of the tension-sensing 3F3/2 kinetochore phosphoepitope and that it modulates the association of certain mitotic checkpoint proteins with kinetochores of mitotic chromosomes. We have also shown that Plk1 accumulation at kinetochores and perhaps its kinase activity are regulated by microtubule attachment to and tension at kinetochores. We now show that inhibition of Plk1 by antibody microinjection causes mitotic cells to exit mitosis prematurely without separating sister chromatids or completing cytokinesis. Moreover, microinjection of anti-Plk1 antibody overrides the spindle checkpoint in cells arrested by treatment with microtubule poison. In contrast, cells arrested at the metaphase-to-anaphase transition by the addition of the 26S proteosome inhibitor, MG132, do not exit mitosis after injection of anti-Plk1 antibody. Thus, proteasome-mediated proteolysis is required for mitotic exit triggered by inhibition of Plk1. The activity of Aurora B, another kinase required for the maintenance of the mitotic checkpoint, is not inhibited by injection of anti-Plk1 antibody. However, inhibition of Aurora B removes both the 3F3/2 phosphoepitope and Plk-1 from kinetochores. These data suggest that Plk1's role in the regulation of the mitotic spindle checkpoint is downstream of Aurora B. Consequently the failure of cells to maintain mitotic arrest after Aurora B inhibition may be due to a subsequent inhibition of Plk1.

125

**Mechanism of Chromosome Positioning on the Spindle Equator in *Drosophila***

H. Maiato,[1] A. J. Pereira,[1] A. Khodjakov,[2] C. L. Rieder[2]; [1]Inst. for Mol. and Cell Biol., Univ. of Porto, Porto, Portugal, [2]Molecular Medicine, Wadsworth Center, Albany, NY

Fully-congressed metaphase chromosomes in *Drosophila* S2 cells remain positioned at the spindle equator after severing one of the two kinetochore fibers (K-fibers) with a laser microbeam (Maiato et al., 2004, JCB, **167**:831-840). Surprisingly, chromosome position is not affected even when one of the K-fibers is cut <1 μm away from the kinetochore, while the other fiber is ~5 μm long. To determine if the kinetochore itself is required to 'anchor' a chromosome at the equator we ablated single kinetochores on metaphase chromosomes in cells stably expressing GFP-Cid/CENP-A (a kinetochore marker). Under this condition chromosomes consistently moved towards the pole to which the remaining kinetochore was attached. Similarly, when metaphase chromosomes were severed through the centromere, between the sister kinetochores, both fragments (each containing a single kinetochore) moved poleward. This movement was not driven by microtubule flux or cytoplasmic dynein, since it was not inhibited in cells treated with nanomolar concentrations of taxol or after depleting dynein heavy chain by RNAi. Finally, when we cut through the arms of metaphase chromosomes tagged with GFP-Histone H2B, the position of the kinetochore-containing chromosome fragment remained unchanged, while acentric fragments moved poleward at a highly variable rate. Thus, the distribution of forces acting on chromosome arms in S2 cells differs from that in vertebrates. Our results reveal that a balance of forces acting on the two sister kinetochores is required to maintain the position of a congressed chromosome at the spindle equator. Further, these forces are not proportional to the length of the K-fibers attached to the kinetochores.

126

**Asator, A Novel Tau-tubulin Kinase Interacts With the Spindle Matrix Complex During Mitosis in *Drosophila***

H. Qi, Y. Ding, L. Zhu, M. J. Blacketer, J. Girton, K. M. Johansen, J. Johansen; Biochemistry, Biophysics & Molecular Biology, Iowa State University, Ames, IA

In *Drosophila* we have recently identified three nuclear proteins, Skeletor, Chromator, and Megator that redistribute during prophase forming a fusiform spindle structure that persists in the absence of polymerized tubulin. The features of this structure are compatible with those of a spindle matrix which on theoretical grounds has been proposed to provide a stationary substrate that anchors molecules during force production and microtubule sliding. Two of these proteins, Skeletor and Chromator, are localized to chromosomes during interphase whereas the third, Megator, occupies the intranuclear space surrounding the chromosomes. Megator is a 260 kD protein with a large $NH_2$-terminal coiled-coil domain which we here show interacts with EAST, another large protein in *Drosophila* that associates with a nuclear nonchromosomal compartment. Furthermore, by yeast two-hybrid interaction assays we have identified a novel tau-tubulin kinase (CG11533) that we have named Asator, which interacts with the $NH_2$-terminal coiled-coil domain of Megator. The kinase domain of Asator is highly conserved and in *Drosophila* alternative splicing gives rise to three isoforms with different $NH_2$-terminal domains. By P-element excision we generated a likely null allele of Asator which eliminates all three isoforms and is homozygous lethal. Transient expression studies in S2 cells revealed that Asator localizes to the cytoplasm at interphase but redistributes to the spindle matrix during mitosis. Thus, these findings indicate that EAST and Asator are likely to be the fourth and fifth members of a group of proteins derived from three different cellular compartments that reorganize during mitosis to interact within a spindle matrix complex. Experiments are in progress to determine how the reorganization of these proteins is coordinated and how the resulting molecular complex affects chromosome dynamics and cell division. (Supported by NSF grant MCB0445182).

127

**The Roles of the Microtubule-Severing Enzymes, Spastin, Fidgetin, and Katanin, in Mitotic Spindle and Chromosome Dynamics**

D. Zhang,[1] G. C. Rogers,[2] D. Buster,[1] D. J. Sharp[1]; [1]Department of Physiology&Biophysics, Albert Einstein College of Medicine, Bronx, NY, [2]Department of Biology, University of North Carolina, Chapel Hill, NC

The poleward flux of tubulin within kinetochore-associated microtubules is important for normal chromatid-to-pole motion during anaphase. This poleward flux requires the active depolymerization of microtubule minus-ends by kinesin-13s and it has been hypothesized that microtubules must be severed from a stabilizing cap on their minus-ends for this to occur. Three members of the AAA (ATPase associated with diverse cellular activities) family of proteins, Spastin, Katanin and Fidgetin have characteristics that make them likely candidates to carry this out. To examine which if any of these proteins function in such a manner, we systematically depleted each (individually and in combination) from Drosophila S2 cells using RNAi. The resulting phenotypes were assessed using 4-D spinning disk confocal microscopy of live mitotic cells stably expressing EGFP-tubulin. Although katanin has long been considered to be the primary microtubule severing enzyme in mitotic cytoplasm, our findings suggest that Spastin and Fidgetin play more prominent roles in mitotic spindle and chromosome dynamics. Specifically, the depletion of Spastin or Fidgetin significantly reduced the velocity of poleward chromatid motility relative to control treated cells ($4.90\times10^{-3}$ or $4.49\times10^{-3}$ vs $7.41\times10^{-3}$ µm/sec, respectively). Alternatively, Katanin depletion resulted in only a moderate and statistically insignificant reduction in poleward chromatid velocities. Analyses of poleward flux and in vivo protein dynamics are currently underway.

128

**Spindle Breakdown is Coordinated by a Global Disassembly Signal in Budding Yeast**

J. N. Molk, E. D. Salmon, K. Bloom; Biology, University of North Carolina, Chapel Hill, NC

Anaphase B in eukaryotes separates the genome prior to the activation of cytokinesis. If the central spindle disassembles prematurely cell viability may be compromised. Spindle breakdown occurs at the end of anaphase when microtubules in the central spindle synchronously disassemble. We have investigated the signal for spindle disassembly in budding yeast using heterokaryons where two spindles form in the same cell. This signal could be global or local. Anaphase onset began asynchronously in cells with two spindles. In both *kar9Δ* and *bik1Δ* cells the spindle that elongated first was often segregated into the daughter and began anaphase approximately eight minutes before the spindle retained in the mother cell (n = 25/37 cells). This supports a local signal for anaphase onset in the nucleus. Preanaphase spindles that repeatedly passed the bud neck displayed a delay in anaphase onset before elongating into the daughter suggesting the local signal responds to movement past the bud neck. However, both spindles broke down within approximately three minutes of each other (n = 28 cells) suggesting spindle disassembly is regulated globally. Spindle breakdown could be delayed if the spindle that elongated into the daughter cell was completely pulled into the bud prior to anaphase onset. These results suggest spindle disassembly occurs via a global signal in budding yeast and this signal is inhibited if the entire spindle enters the bud.

129

**Molecular Pathways Ensuring the Coordination of Late Cytokinetic Events with Chromosome Segregation**

Y. P. Barral, C. Norden, J. Dobbelaere, M. Mendoza; Biology, Swiss Federal Institute of Technology, Zürich, Switzerland

During anaphase, spindle elongation and shrinkage of kinetochore microtubules pull sister chromatids apart, while cytokinesis cleaves the cell between the two separated copies of the genome. How the cell ensures that spindle elongation fully separates sister chromatids along their entire length and clears the cleavage plane of chromatin is still unknown. Indeed, to fulfill this requirement the spindle must become more than twice as long than the longest chromosome arm, and spindle breakdown and the completion of cytokinesis must be delayed until that length is reached. We use budding yeast as a model to investigate the mechanisms linking chromosome separation and cell cleavage. Here we report on two opposite signaling pathways, NoCut, and Reversion-of-NoCut, that fine-tunes the timing of abscission relative to chromosome segregation. Abscission is the last and only irreversible event of cytokinesis. NoCut depends on the integrity of the spindle midzone, the aurora kinase Ipl1, the anillin-related proteins Boi1 and Boi2, and represses abscission during anaphase and in response to chromosome separation defects. Inactivation of this pathway increases the frequency of chromosome breakage by the cleavage machinery in anaphase compared to wild type. Furthermore, simultaneous inactivation of NoCut and impairment of spindle elongation causes extensive chromosome breakage and cell death. In these cells, impairment of cytokinesis suppresses chromosome breakage, demonstrating that NoCut prevents chromosome breakage by the cleavage machinery. Reversion-of-NoCut depends on centromeric chromatin, proper kinetochore assembly and PP2A activity, and upon proper chromosome separation it is required

to revert the NoCut-dependent inhibition of abscission. Thus, together our results suggest that a sensing mechanism monitors chromosome separation and/or the presence of chromatin in the midzone area to ensure that cytokinesis is completed only after that the spindle has reached the right size.

## G1-S/DNA Replication (130-142)

### Cell Cycle Dynamics Analysis of Chromatin Proteome in Xenopus Egg Extract

G. A. Khoudoli,[1] I. M. Porter,[1] G. X. Stewart,[1] J. S. Andersen,[2] J. R. Swedlow,[1] J. Blow[1]; [1]Division of Gene Regulation and Expression, University of Dundee, Dundee, United Kingdom, [2]University of Southern Denmark, Odense, Denmark

The Xenopus cell free egg extract recapitulates most events of early embryonic cell cycles on added demembranated sperm nuclei. We have employed this system for proteomic analysis of mitotic chromosomes and interphase chromatin at different stages of DNA replication. Reconstituted mitotic chromosomes or chromatin progressing through S-phase in the presence or absence of various replication inhibitors were isolated and proteins bound to DNA were eluted and subjected to proteomic analysis. We optimized sample preparation for 2D gel electrophoresis using Taguchi method (Khoudoli et al., Proteome Sci. 2004, 2:6). The resulting protocol, substantially improved the solubility and resolution of protein mixtures derived from a variety of sources on 2DE. Using 2DE and LC/MS/MS, we have identified 50 candidate polypeptides that associate with chromatin in a cell cycle- and replication-dependent manner and 9 uncharacterized proteins on mitotic chromosomes. Known components of replication machinery with expected behaviour, such as ORC and Mcm proteins, were among identified the polypeptides. An analysis of individual spots by immunoblotting and mass spectrometry revealed previously uncharacterized posttranscriptional modifications of Mcm(2-7). To assess the functional role of candidate proteins we raised antibodies against 9 polypeptides that were not previously associated with replication. An immunocytochemical analysis of replicating nuclei in Xenopus egg extract demonstrated that 7 of 9 antibodies recognised epitopes only in interphase nuclei and showed no staining on metaphase chromosomes. We are currently using these antibodies to verify the response of the proteins to cell cycle progression and to conduct functional studies. Our preliminary data shows that two candidate proteins participate in a functional complex. siRNA approach for the functional analysis was established and validated in study of novel proteins identified to be associated with mitotic chromosomes reconstituted in Xenopus egg extract.

131

### The Function of Mus81 in the Absence of Sgs1 in *Saccharomyces cerevisiae*-Study of Mus81 Ts$^-$mutants

M. Ii, T. Ii, S. J. Brill; Molecular Biology and Biochemistry, Rutgers University, Piscataway, NJ

Mus81-Mms4 is a conserved structure-specific endonuclease. In vitro, the budding yeast enzyme cleaves 3' flaps from a variety of branched DNA substrates. Defects in *MUS81* or *MMS4* result in strong CPT and MMS sensitivity, weak UV sensitivity, and sporulation defects, suggesting Mus81-Mms4 functions in DNA repair and meiosis. *MUS81* and *MMS4* are essential in the absence of *SGS1* or *TOP3* that encode DNA helicase and DNA topoisomerase, respectively. This suggests that Mus81-Mms4 shares overlapping function with Sgs1-Top3. The synthetic-lethality of *mus81 sgs1* is suppressed by deletion of *RAD51*. Rad51 is a component of homologous recombination (HR) machinery. Therefore, Mus81-Mms4 has been thought to function in the HR pathway like Sgs1-Top3. However, we found that *MUS81* functions primarily in a *RAD51*-independent manner and that only *SGS1* acts downstream of *RAD51*. This suggests that Mus81-Mms4 may not function in the HR pathway. To understand what function Mus81-Mms4 has in the absence of Sgs1-Top3, we carried out a screen of Mus81 Ts$^-$ mutants. PCR-mutagenized *MUS81* was transformed into a *mus81 sgs1* strain carrying wt *SGS1* on a *URA3 CEN* plasmid together with linearized *TRP1 CEN* plasmid harboring homologous regions of *MUS81*. The transformants were subjected to 5-FOA selection and then the viable cells were transferred to YPD plates and examined temperature-sensitivity. The candidates were confirmed if the Ts$^-$ phenotype depends on the *TRP1* plasmid. The Ts$^-$ mutants obtained show severe defects in cell cycle progression in *sgs1* background. Pulsed-field gel analysis revealed that the chromatin structure of Mus81 Ts$^-$ mutants in *sgs1* background changed at non-permissive temperature. Moreover, morphology of Mus81 Ts$^-$ mutants in *sgs1* background changed dramatically after shifting to 37°C. We will present further analysis of the mutant phenotype and discuss the results.

132

### Mutation Rate Analysis in Novel *Schizosacchromyces pombe* replication initiation defective (*rid*) strains

J. M. Sierra-Montes, G. D'Urso; Molecular and Cellular Pharmacology, University of Miami Miller School of Medicine, Miami, FL

We have recently discovered a novel checkpoint phenotype associated with mutants defective in DNA replication initiation called *rid* (for replication initiation defective). When grown under semi-permissive conditions, *rid* mutants display a cell cycle delay that is *chk1*-dependent, *cds1*-independent suggesting that a novel checkpoint pathway is activated. By analyzing mutation rates in the presence or absence of *chk1*, we have determined whether the checkpoint plays a role in either the stimulation or suppression of a mutator phenotype. For each *rid* mutant, mutation rates were also measured in the absence of *cds1+* or in the absence of both *chk1+* and *cds1+*. The forward mutation rate assays using 5-fluoroorotic acid (FOA), which detects mutations inactivating the *ura4+* gene, and canavanine, which selects against *CAN1+*, were used for the identification of the mutator phenotype. Interestingly, we have found that *rid* mutants, in contrast to mutants that delay S phase progression, do not display a mutator phenotype suggesting that blocks to initiation may be less mutagenic than blocking chain elongation. The data shows that no *rid* strain at their respective *rid*-activation temperature displays a mutator phenotype in the presence of both *chk1+* and *cds1+*. However, in the absence of *chk1+*, some of the *rid* strains (*i.e* cdc20-M10) display an increase in mutation rate, consistent with *Chk1+* having a role in preventing accumulation of DNA damage when replication initiation is delayed. As expected, no such increase in mutation rates was observed in the absence of *cds1+*. Therefore, we conclude that *chk1+* is required during the cell cycle, either at the G1/S phase transition, or later in G2, to protect cells from DNA damage caused by blocks to DNA replication initiation.

133

### Chromatin Modification Regulates Rad9 Function in DNA Damage Checkpoint Response

R. Wysocki,[1] A. Javaheri,[1] S. Allard,[2] J. Cote,[2] S. J. Kron[1]; [1]Center for Molecular Oncology, University of Chicago, Chicago, IL, [2]Laval University

Cancer Research Center, Hotel-Dieu de Quebec (CHUQ), Quebec City, PQ, Canada
The prevailing model for DNA damage checkpoints is based on studies in budding yeast that suggest single strand DNA formed via 5'-3' resection at double strand breaks (DSBs) is both necessary and sufficient for checkpoint arrest. However, the megabase domains of phosphorylated histone H2AX formed rapidly at DSBs in metazoans recruit BRCA1, 53BP1, MDC1 and other checkpoint signaling proteins, and recent data implicate chromatin regulators in yeast DNA damage response. The relative significance of DNA damage processing and/or chromatin modification in determining checkpoint response remains poorly defined. Using the yeast G1 checkpoint response to DSBs as a model, we have established essential roles for chromatin modification in DNA damage signaling and cell cycle arrest. A genomic screen for G1/S checkpoint defects after ionizing radiation revealed the conventional checkpoint regulators but also the Dot1 histone H3 Lys79 methylase. Molecular analysis demonstrated that activation and function of the 53BP1 homolog Rad9 requires assembly onto chromatin adjacent to DSBs. This assembly is mediated by binding between Rad9 tudor domains and H3 methyl-Lys79. Mutants failed to activate Rad9 or Rad53 or perform G1 arrest. Defects in the Tel1/Mec1 dependent phosphorylation of histone H2A Ser129 also attenuate Rad9 function. By contrast, loss of NuA4-dependent acetylation of histone H4 amino-terminal tails promotes Rad9 signaling and delays checkpoint recovery. These data suggest 1) a histone code for DNA damage response, mediated by both constitutive and regulated modifications and 2) a role for DSBs in assembling a chromatin domain required for DNA damage checkpoint signaling. Insofar as 5' resection of DSBs may be blocked in G1, thereby eliminating ssDNA as a potential signal, we hypothesize that assembly of Rad9 onto chromatin at sites of DNA damage may be both necessary and sufficient for yeast G1 checkpoint arrest.

134

**Population Polymorphisms in *Sciara* DNA Puff II/9A Reveal Conservation of Origin *Cis*-elements**

E. A. Gustafson, Y. Yamamoto, H. Smith, S. A. Gerbi; Mol Bio, Cell Bio, Biochem., Brown Univ. BioMed Div., Providence, RI

DNA puffs of the larval salivary gland polytene chromosomes of the fly *Sciara coprophila* exhibit developmentally regulated tissue-specific DNA amplification. We have sequenced an 8.9 kb sequence from DNA puff II/9A. It initiates replication from a small 1 kb origin region during amplification. The top strand transition point (TP1) between leading and lagging strand synthesis has been mapped to a single nucleotide within the 1 kb origin. A DNase hypersensitivity site (DHS) is found upstream of TP1 and a region of bent DNA is located between the DHS and TP1. Downstream of the origin are II/9A genes 1 and 2. Putative ecdysone response elements (EcREs) are present in the origin and promoter regions. PCR of the genomic *Sciara* II/9A locus revealed a series of multiple-sized PCR products. Cloning and sequencing showed several sequence insertions and deletions along with stretches of novel sequence relative to the previously cloned II/9A locus. These sequence insertions and deletions are present throughout development, are not tissue-specific, and are all located on the same DNA molecule. We believe they represent a population polymorphism found in *Sciara.* Heterozygous adults and homozygous adults for the polymorphisms have been observed. Any specific DNA sequences or spacing requirements important for regulating amplification of the II/9A locus should be conserved between the two polymorphic sequences. Indeed, a 9 nucleotide sequences present at TP1 and at putative TP2 as well as several putative ecdysone response elements are preserved. Insertions and deletions upstream of the 1 kb origin occur within a conserved sequence. However, some novel sequence stretches are located on the right side of the 1 kb origin region proximal to the gene II/9-1 promoter. This suggests that these sequences may not be as crucial as the upstream sequences.

135

**Does the Ecdysone Receptor Mediate DNA Puff Amplification in the Fly *Sciara*?**

J. Johnson, J. M. Waggener, M. S. Foulk, Y. Yamamoto, M. Ezrokhi, H. Smith, N. Wu, S. A. Gerbi; Mol Bio, Cell Bio, Biochem., Brown Univ. BioMed. Div., Providence, RI

Circumstantial evidence suggests that the ligand-bound transcription factor, ecdysone receptor (EcR), may induce repeated rounds of re-replication, resulting in DNA amplification at DNA puffs of larval salivary gland polytene chromosomes of the fly *Sciara.* DNA sequence analysis of the largest DNA puff at locus II/9A revealed potential binding sites for EcR at the amplification origin (ORI EcRE) as well as at the transcription promoter that is 2.5 kb downstream of the origin. To investigate the possibility of steroid hormone regulation of DNA replication/amplification, we have cloned and sequenced the two isoforms of *Sciara* EcR (EcR-A and EcR-B) and produced polyclonal antibodies against isoform-specific peptides. We also cloned and sequenced *Sciara* ultraspiracle (USP), the heterodimer partner of EcR. Gel shifts showed that the "Ori EcRE" can bind *in vitro* expressed *Sciara* EcR-A/USP and EcR-B/USP heterodimers. We determined the developmental profile of EcR-A and EcR-B expression by Real Time PCR using EcR-A or EcR-B isoform-specific primers; we sequenced DNA encoding *Sciara* 18S rRNA to use as a normalization control. EcR-A and EcR-B mRNAs were relatively constant in whole animals throughout development, with a slight (~ 1.5 fold) increase in expression observed for EcR-A during *Sciara* mid-larval and early pupal stages and an (~ 3 fold) increase of EcR-A expression in pupal stages. The expression levels of EcR-A and EcR-B in *Sciara* salivary glands was similar to that in whole larvae, but there was a more pronounced increase in EcR-A at mid-larval stage (~8 fold) and also at the early pupal stage (~8 fold). The developmental profile of protein expression for *Sciara* EcR-A and EcR-B mirrored that of mRNA expression. The increase in EcR-A in salivary glands at amplification stage implied a possible role for this hormone receptor in DNA re-replication.

136

**Ecdysone Induces *Sciara* Puff II/9A DNA Amplification**

M. Foulk, Y. Yamamoto, C. Liang, D. Alam, S. A. Gerbi; Mol Bio, Cell Bio, Biochem., Brown Univ. BioMed Div., Providence, RI

DNA puffs of *Sciara* salivary gland polytene chromosomes undergo DNA amplification, overriding the control that an origin fires only once per round of genomic replication. We have focused on DNA puff II/9A which amplifies ~17 fold. Our data suggest that DNA amplification is controlled by the steroid hormone, ecdysone. Salivary glands from pre-amplification stage larvae were cultured in Cannon's medium with and without ecdysone. Subsequently, Southern blots were probed for DNA puff II/9A and the unamplified III/9B RNA puff as a control. Determination of the ratio between the signals revealed the fold amplification. Salivary glands amplified about 2-fold after one day of culture and about 12-fold after two days, indicating that ecdysone is involved in amplification. There was no amplification after incubation in medium lacking ecdysone. Cycloheximide or actinomycin D inhibited ecdysone induced amplification. Salivary glands from post-amplification stage larvae could not be induced to amplify further. To study this induction *in vivo*, larvae from pre-amplification stages were injected with 32 ng of ecdysone or 50%

ethanol (mock). Subsequently, the amplification level in genomic salivary gland DNA was assessed by quantitative PCR using primers specific to DNA puff II/9A and RNA puff III/9B. Amplification of the II/9A locus was determined by comparison to the ratio of the signal of II/9A:III/9B in adult DNA (ratio in adult = 1). In contrast to mock-injected larvae (no amplification: 1.2 +/-0.35), the ecdysone-injected larvae demonstrated a range of amplification up to 12.9 +/- 2.75 fold. The level of ecdysone-induced amplification generally correlated with the extent of the pre-pupal phenotype. These results suggest that ecdysone plays a role in the induction of DNA amplification. Further work will determine if this function is direct, as suggested by putative ecdysone response elements at the DNA puff II/9A origin.

137

**Regulation of Cell Cycle Progression in Immortalized Human Mammary Epithelial Cells by Eukaryotic Initiation Factor 4E**

S. Li, O. Issaenko, S. Avdulov, R. McMullen, M. Peterson, P. Bitterman, V. Polunovsky; Pulmonary Medicine, University of Minnesota, Minneapolis, MN

Eukaryotic translation initiation factor 4E (eIF4E) is the mRNA cap binding protein and is rate limiting for translation initiation. Many human malignancies, including human breast cancer, over express eIF4E, which is associated with a poor prognosis. Previously we found that over expression of eIF4E confers chemically immortalized human mammary epithelial cells (HMEC) with two crucial hallmarks of malignant conversion - autonomy for survival and growth signals. We extended these initial experiments using HMECs harboring the hTERT gene to examine mechanisms governing translationally regulated autonomy in cells with a defined genetic constitution. Here we show that over expression of eIF4E in HMEC/hTERT produces cells that form transformed foci on plastic in sparse culture and grow in an anchorage-independent manner in agar. These cells have a reduced requirement for extracellular signals to survive and to progress through the cell cycle when cultivated in chemically defined medium supplemented with insulin and/or EGF. Ectopic expression of eIF4E in growth factor deprived cells increased cell cycle entry in response to insulin and EGF, and accelerated G0-to-S transit of the stimulated cells. Moreover, in contrast to their non-transduced counterparts, a subpopulation of HMEC/hTER/eIF4E cells synthesized DNA even in the absence of growth factors. These alterations are associated with elevated phosphorylation of Rb at cdk4/6 and cdk2 specific sites, as well as with increased levels of cyclins D1 and E. Our observations show that up-regulated eIF4E acts as a proto-oncogene that mimics growth factor signaling by activation of a subset of key G1/S checkpoint regulators. Thus, hyperactivation of the cap-dependent translation apparatus can function as a specific component of the malignant transformation pathway, which promotes clonogenic expansion by reducing cell dependence on growth and survival signals and a proper substratum.

138

**Function of Human Polo Like Kinase-2 in Centriole Duplication**

I. Hoffmann,[1] O. Cizmecioglu,[1] S. Duensing[2]; [1]DKFZ, Heidelberg, Germany, [2]Dept. of Molecular and Cell Biology, Pittsburgh, PA

Centrosomes contain a pair of centrioles that duplicate once during the cell cycle to give rise to two mitotic spindle poles, each containing one old and one new centriole. Centriole duplication initiates at the G1/S transition in mammalian cells, and is completed during S and G2 phase. The localization of a number of protein kinases to the centrosome has revealed the importance of protein phosphorylation in controlling the centrosome duplication cycle. The centrosome cycle needs to be tightly coordinated with the cell division cycle. A central part of our ongoing studies is the functional characterization of the human polo-like kinase (Plk) family member Plk2. Plk2 kinase activity peaks during the G1 phase of the cell cycle. Plk2 localizes to the centrosome and is involved in the regulation of centriole duplication. Two characteristic sequence motifs in Plks, the polo boxes, are required for targeting the respective kinase to various structures during cell cycle progression. We find that kinase dead Plk2 (Plk2-NA) functions as competitor of endogenous Plk2 for centrosomal binding. However, kinase-dead Plk2 with a point mutation in the polo box region (Plk2-NAWF) reveals a reduced binding to the centrosome suggesting that binding occurs in a polo box dependent manner. Furthermore, using a GFP-centrin1 cell line we find that Plk2 localizes to the mother centriole during G1 phase and then localizes to both mother and daughter centriole during S phase. siRNA-mediated down-regulation of Plk2 leads to mitotic spindle abnormalities as an apparant failure of duplication of centrioles. To further assess the function of Plk2 in both centriole duplication and G1-Phase, we have performed a screen for Plk2 substrates. We will report our progress in the characterization of these substrates in centrosome function.

139

**Regulation of G1/S Phase Transition and APCCdh1 by Reactive Oxygen Species**

C. G. Havens, S. F. Dowdy; Cellular and Molecular Medicine, University of California San Diego, La Jolla, CA

Dividing cells have a higher metabolic rate than quiescent cells and metabolism has been suggested to influence cell proliferation. To investigate the role of metabolism in cell cycle progression we examined cell size, mitochondrial mass and reactive oxygen species (ROS) levels in highly synchronized cell populations progressing from early G1 to S phase. We found that ROS increased dramatically compared to cell size and mitochondrial mass. Since ROS have been shown to play a role in cell proliferation and transformation, we hypothesized that ROS could contribute to cell cycle progression. Therefore, using antioxidants, we prevented the increase in ROS and found that cells arrested in late G1 after transition across the restriction point, with active cyclin E:cdk2 kinase, and inactive hyperphosphorylated pRb. However, cells failed to accumulate cyclin A protein and therefore activate cyclin A:cdk2 kinase, even in the presence of cyclin A mRNA. Further examination revealed that cyclin A was ubiquitinated by the Anaphase Promoting Complex (APC) and degraded in a proteasome dependant manner. Furthermore, the antioxidant arrest could be rescued by overexpression of Emi1, an inhibitor of APC. This work demonstrates that the accumulation of a critical level of endogenous ROS are necessary for inactivation of the Anaphase Promoting Complex to allow S phase progression.

140

**Novel Function of Muskelin in Cell Cycle Progression**

M. Valiyaveettil, J. C. Adams; Department of Cell Biology, Lerner Research Institute, Cleveland Clinic Foundation, Cleveland, OH

Adhesion of normal cells to extracellular matrix is important for their progression through the cell cycle. This regulation acts mainly in the G1 phase of the cell cycle. Muskelin is an intracellular protein originally characterized by its ability to increase cell spreading on the extracellular matrix protein, thrombospondin-1. Muskelin is a multidomain protein that is a unique and conserved member of the kelch-repeat superfamily of

proteins [Biochem. J. (2004), 381, 547-559]. Muskelin is present throughout the cell-cycle, with increased levels in late G1 and S phase. The objective of this work is to analyze the hypothesized functional role of muskelin in the cell cycle, using over- and under-expression studies. GFP- or FLAG- tagged muskelin were over-expressed in muskelin-negative Cos-7 cells and the cell cycle profile analyzed by flow cytometry after 72h. Compared to GFP-expressing cells, over-expression of muskelin resulted in a significant increase in cells with 4n DNA content. Domain deletions were used to map activity to the kelch-repeats and C-terminus. Microscopic analysis indicated a point of inhibition during entry into mitosis. Stable expression of shRNA vectors was used to deplete endogenous muskelin in A549 human lung epithelial cells. In 4 clonal cell lines analysed with $\geq$ 60% depletion of muskelin, the proportion of cells with 2n DNA content was significantly increased. In these lines, cells were flatter with altered, discontinuous, mobile ruffles. At molecular level, the cells had a normal content of cyclin D1, but had reduced hyperphosphorylated Rb (retinoblastoma protein), with partial reduction in phosphorylation at S780 and severe reduction of phosphorylation at S807/S811. Cyclin A protein was also reduced. These studies implicate muskelin in the regulatory network upstream of Rb phosphorylation that controls cell cycle progression into S phase.

141

### A Septin-dependent Pathway for Bud Morphogenesis during G1

T. A. Egelhofer, D. R. Kellogg; MCD Biology, UCSC, Santa Cruz, CA

The septins are a family of conserved proteins that have been implicated to function late in the cell cycle, where they have been shown to play a role in cytokinesis and controlling cell cycle progression during G2/M. However, many septin alleles show synthetic lethal interactions with the G1 cyclins *CLN1* and *CLN2*, suggesting that the septins may also play an earlier role in the cell cycle. To understand the role septins play during G1, we created a *cln1Δcln2Δ* strain with a temperature sensitive allele of *CDC12*. When these cells were synchronized in early G1 and released at the restrictive temperature, the cells were unable to form buds with a normal morphology and they largely failed to direct growth to the daughter bud. We next tested whether Shs1, a non-essential septin, is also synthetically lethal with *cln1Δ cln2Δ*. We constructed a *shs1Δcln1GAL-CLN2* strain that grew normally on galactose, but failed to grow on dextrose. Most of the cells arrested as either large unbudded cells or with small, poorly formed buds. In addition, many of the cells failed to localize the other septins, while others showed diffuse septin localization over one end of the cell or weak septin staining at the bud neck. These results suggest that Shs1 functions in a unique pathway that plays a role in bud morphogenesis and septin function. Since Shs1 is required for viability only in the absence of Cln1 and Cln2, it may function in a pathway that is initiated by the other G1 cyclins, *PCL1* and *PLC2*. We found that Shs1 phosphorylation was significantly reduced in *pcl1Δpcl2Δ* cells upon release from a G1 arrest. Taken together, these results suggest that the septins play an important role early in the cell cycle to regulate the pattern of growth.

142

### Knockdown of Human Mcm10 Activates G2 Checkpoint Pathway

J. Park,[1] K. Lee,[1] D. Hwang[2]; [1]Institues of Molecular Biology and Genetics, Seoul National University, Seoul, Republic of Korea, [2]Department of Biological Sciences, Seoul National University, Seoul, Republic of Korea

MCM10 is required for DNA replication initiation by recruiting Cdc45 and DNA polymerase alpha in *S. pombe* and *X. laevis*. To investigate the roles in human DNA replication, we performed hMCM10 siRNA experiment. The siRNA treatment increased the cells in G2/M. No increase of phospho-H3 suggests that the treated cells are arrested in G2 phase rather than M phase. This arrest appears to be caused by G2 checkpoint activation through Wee1 pathway. Our results suggest that the certain level of hMCM10 is necessary for completion of chromosome replication and progression of cell cycle to mitosis.

## Actin (143-150)

143

### A Single Pointed End Mutation Abolishes Polymerization in Yeast Actin

D. J. Teal, J. F. Dawson; Molecular and Cellular Biology, University of Guelph, Guelph, ON, Canada

The development of nonpolymerizing actin mutants is central to obtaining crystal structures depicting actin dynamics. While it was thought that polymerization-defective actins could only be coexpressed in yeast cells, we show that yeast can express a non-polymerizing actin mutant as its sole source of actin. Yeast actin possessing an A204C mutation (AC-actin) at the pointed end does not polymerize when purified, even at 0.1 mM concentration. Yeast cells expressing AC-actin grow slower than wild type cells (3 hours versus 2.5 hours doubling times) with cold and osmolarity sensitivity and possess abnormal F-actin cables. Monitoring light scattering at 360 nm resulted in no observable polymerization with 5 uM AC-actin. Electron micrographs of AC-actin polymerization reactions revealed no filaments, ruling out the formation of short filaments. Polymerization of 5 uM AC-actin is rescued in the presence of 5 uM phalloidin. Partial polymerization of 5 uM AC-actin in the presence of 7.5 uM non-muscle tropomyosin was observed, while no polymerization of 10 uM AC-actin was seen in the presence of 10 uM myosin subfragment-1. Copolymerization experiments containing 5 uM wild type yeast actin and 0, 1.6, 5, or 15 uM AC-actin exhibited a similar maximum concentration of F-actin, suggesting that only wild type actin participated in filament formation. The elongation rate increased with increasing concentrations of AC-actin, suggesting that AC-actin participated in the formation of nuclei from which wild type yeast actin polymerized from the free barbed end. This hypothesis is supported by the slight decrease in maximal F-actin concentration with increased AC-actin concentration, suggesting the presence of increased numbers of shorter filaments. This evidence supports the hypothesis that AC-actin acts as a pointed-end nucleating and capping protein and that AC-actin is a candidate for structural studies including important actin binding proteins.

144

### Hydrophobic Loop Mutant F-actin Stability/Instability due to Disulfide Bond Formation

D. C. Scoville,[1] J. Stamm,[1] D. Toledo Warshaviak,[1] A. Shvetsov,[1] P. Rubenstein,[2] W. Hubbell,[1] E. Reisler[1]; [1]Biochemistry and Molecular Biology, UCLA, Los Angeles, CA, [2]Biochemistry, University of Iowa, Iowa City, IA

It has been postulated that the hydrophobic loop of actin (residues 262-274) swings out and assists in actin filament formation and stabilization. We have shown previously that “docking” of this loop to the monomer surface via intramolecular disulfide bonds in yeast actin mutant

L180C/L269C/C374A in G- or F-actin prevents the formation of filaments or destroys them, respectively (Shvetsov, 2002). Here, we analyzed F-actin dynamics utilizing four hydrophobic loop mutants that have cysteine residues introduced at a single location along the yeast actin loop. Lateral, copper-catalyzed disulfide cross-linking of the mutant cysteine residues to the native C374 in the neighboring strand within the filament was fastest for S265C, followed by V266C, L267C, and L269C, respectively. This data is not consistent with the Holmes model of F-actin, but is reinforced by electron paramagnetic resonance (EPR) measurements, showing that S265C lies closest to C374 within the filament, followed by V266C, L267C, and L269C, respectively. Single cysteine EPR analysis of each of the four mutant residues within the loop demonstrated the mobility of the S265C residue, whereas the V266C, L267C, and L269C residues were progressively less mobile within F-actin. Electron microscopy revealed normal filament morphology for the cross-linked mutant S265C and V266C filaments. However, cross-linking destabilized L267C and L269C filaments; only very short filaments could be observed in electron micrographs. These results illustrate the inherent dynamics of the 262-274 loop, including its ability to populate conformational states that destabilize the filament. Such states may be exploited within a cell by filament destabilizing factors. Research supported by grants from the NSF and NIH.

145

**The Real-Time Monitoring of the Folding State of Tetramethylrhodamine Labeled Actin**

A. A. Perieteanu, B. Sweeting, J. F. Dawson; Molecular and Cellular Biology, University of Guelph, Guelph, ON, Canada

Current methods to measure the folding state of actin generally involve techniques such as circular dichroism, differential scanning calorimetry, or fluorescence requiring cost-intensive instrumentation. Chemical modification of actin with 5'-tetramethylrhodamine (TMR-actin) has been used to visualize filament growth, cytoskeletal interactions, and protein structure. We show that the folding state of actin can be monitored using a change in absorbance properties of TMR-actin employing visible light at 557nm. Using this absorbance as an assay, the relative stability of TMR-labeled skeletal muscle actin was determined in the presence of $Mg^{2+}$, $Ca^{+2}$, and various nucleotides, as well as varying TMR-actin concentrations. The melting temperature ($T_M$) of $Ca^{+2}$-ATP TMR-actin was concentration dependent, however at concentrations above 5 uM a consistent $T_M$ of 62.55 ± 0.1ºC was measured, compared to 62.50 ± 0.6ºC measured for unlabelled actin using an independent assay. Mixing experiments showed that the ratio of TMR-actin to wild type actin in solution did not affect the measured $T_M$. We observed that that $Mg^{+2}$-ATP TMR-actin is less thermostable than $Ca^{+2}$-ATP TMR-actin in both filamentous and globular forms. We monitored the polymerization kinetics and filament stability for various ratios of TMR-actin:actin copolymers. Stabilizing and destabilizing effects of gelsolin segment 1, DNAse I , myosin S1, tropomyosin, and phalloidin were observed for globular actin and filamentous actin. An advantage to using this simple and inexpensive method is its ability to directly analyze the folding state of TMR-actin without interference from actin binding proteins. This method shows increased sensitivity over other spectroscopic methods, and allows for the thermal analysis of TMR-actin at lower concentrations than commonly used methods such as differential scanning calorimetry.

**Conformational States of the Nucleotide Cleft in Actin**

D. S. Kudryashov, D. T. Warshaviak, E. Reisler; Chemistry and Biochemistry, UCLA, Los Angeles, CA

Actin is one of the most abundant and conserved eukariotic proteins. The polymerization of actin, which is accompanied by ATP hydrolysis, is a driving force for many cellular processes, including cell migration. Actin recognition by regulatory proteins depends on the state of ATP hydrolysis rendering these states critical to the regulation of actin-based motility. It has been suggested that the nucleotide cleft in actin opens upon ATP hydrolysis and Pi release, but this was questioned by others. Recently we demonstrated that the solution methods used for examining the cleft conformation yield ambiguous results. To probe directly the cleft and monitor changes in the intra-cleft distances, we introduced cysteins at each side of the nucleotide cleft of yeast actin and substituted the reactive Cys374 with serine (CCS mutant). The resulting mutant supports yeast growth at rates similar to wild type actin cells, indicating that the in vivo functional properties of the mutant are not perturbed. Most of the in vitro properties of the CCS mutant are similar to these of wild type actin. This includes the rates of tryptic and subtilisin digestion of the subdomain 2 region, the nucleotide exchange rates under all conditions tested (CaATP, MgATP, and MgADP), and nucleotide exchange inhibition by gelsolin segment 1 and DNase I. These observations suggest strongly that the CCS mutant of yeast actin is a good model for monitoring conformational changes in the cleft region. Using homobifunctional thiol cross-linking reagents, we found that the shorter span reagents cross-link actin with increasing efficiency in the following order of states: Mg-ADP-G-actin, Ca-ATP-G-actin, Mg-ATP-G-actin, and Mg-ATP-phalloidin stabilized F-actin. Although, these data do not yield definitive distances within the cleft, they reveal the tendency of actin to adopt an increasingly closed cleft conformation in the above order of states.

**Evidence for Four Steps in the Thermal Denaturation of F-Actin**

C. R. Gicquaud, B. Heppell; Chimie-Biologie, Université du Québec à Trois-Rivières, Trois-Rivières, PQ, Canada

With the development of differential scanning calorimeter (DSC), the *in vitro* study of the unfolding process of proteins has become a subject of increasing interest. Several of these studies were done with actin, where domains of this molecule have been suggested and interactions with ligands characterized. However, the previous studies done with actin, as with many other proteins, were carried out at only one scanning rate and at one protein concentration. The objective of the present work is to analyze the thermal denaturation of F-actin with DSC under different experimental conditions. The steps revealed by the thermograms were identified by CD spectroscopy and probe fluorescence. We found that changing the protein concentration and the scanning rate completely modified the aspect of the thermograms, casting doubt on previous conclusions. We were able to resolve the thermal denaturation of actin into four steps. The first is centered at 45°C, and the fluorescence of pyrene-actin suggests that it is a depolymerization or a fragmentation; this step is reversible. The second step at 56°C, accompanied by an increase of the fluorescence of ε-ATP, is probably a release of the nucleotide from its binding site; this second step is irreversible. The third step at 57-64°C is a change in the environment of the tryptophanes, as shown by the intrinsic fluorescence. The fourth step is the unfolding of the peptide chain, as revealed by CD spectra and ANS fluorescence. From the thermograms, we have measured the calorimetric enthalpy for the unfolding of F-actin to be 64 megaJ/mole, (1 400 J/g), a value much larger than those obtained for other proteins. Since denaturation and stability are closely related, this particularity of actin could be an adaptation of its role as a protein that transmits forces.

**Rapid and Reversible Optical Switching of Protein Fluorescence in Living Cells**

S. Mao,[1] T. Sakata,[1] T. Gomez,[2] G. Marriott[1]; [1]Physiology, University of Wisconsin-Madison, Madison, WI, [2]Anatomy, University of Wisconsin-Madison, Madison, WI

We present a new approach to bring about rapid and reversible, optical switching of protein fluorescence within living cells. We have developed a family of thiol reactive optical switches that undergo rapid and reversible transitions between a colorless spiro (SP) state and a colorful merocyanine (MC) state - the two states of the switch are efficiently controlled through alternate excitation of SP with 365 nm light (SP to MC), and MC with 543 nm light (MC to SP) - unexpectedly, MC is shown to decay to the ground state with the emission of red (620-650 nm) fluorescence. The advantages of our optical switch conjugates for switching protein fluorescence over other approaches include: 1), Optical transitions between the SP and MC states are rapid and fully reversible and can be realized using 1-photon and 2-photon (SP to MC) excitation; 2), Optical transitions between SP and MC do not release photoproducts; 3), The absorption of the MC to SP transition can be tuned over a broad wavelength range (>500~650 nm). We show that cells loaded a BIPS-actin conjugate exhibit MC fluorescence (650nm) when excited with 543 nm light. Stronger illumination of the MC-conjugate with 543 nm light generates the non-fluorescent SP-actin; on the other hand, excitation of SP-actin with a short pulse of 365 nm light regenerates the fluorescent MC-actin. The cycle of optical switching between SP- and MC-actin can be repeated over many excitation cycles (>20) with high fidelity and shows little evidence of fatigue. The ability to use light to rapidly and reversibly modulate MC-fluorescence of a protein conjugate should prove useful in FRAP/photoactivation of fluorescence and speckle microscopic analyses of dynamic cellular processes.

**Orientation of F-actin in the Contractile Ring in Fission Yeast**

T. Kamasaki,[1,2,3] M. Osumi,[2,4] I. Mabuchi[3]; [1]Department of Oral Histology, School of Dentistry, Showa University, Tokyo, Japan, [2]Division of Material and Biological Function Sciences, Graduate School of Science, Japan Women's University, Tokyo, Japan, [3]Division of Biology, Graduate School of Arts and Sciences, University of Tokyo, Tokyo, Japan, [4]Institute of Medical Mycology, Teikyo University, Tokyo, Japan

Cytokinesis in animal and primitive eukaryotic cells is executed by constriction of the contractile ring which is formed underneath the plasma membrane at the division plane. F-actin and myosin-II are main components of the contractile ring, but little is known about the arrangement of F-actin in the ring. Here, we show the entire arrangement of F-actin decorated with myosin subfragment 1 in the contractile ring in fission yeast cells. In equatorial serial sections of the whole ring, numbers of actin filaments oriented reversely from each other were roughly 1:1. These filaments were not homogeneously mixed in the ring, but those showing the same directionality tended to cluster in the ring. The average length of each filament was less than 1 μm indicating that the actin filaments are staggered in the ring. This study provides us with an insight into how the contractile ring is formed and how it contracts.

150

**Modulation of the Actin Cytoskeleton of the Anterior Pituitary Folliculostellate Cells TtT/GF by Pro-Inflammatory Cytokines**

S. Solinet, M. L. Vitale; Pathology and Cell Biology, Université de Montréal, Montréal, PQ, Canada

In the anterior pituitary, the folliculostellate (FS) cells are agranular cells with distinct functions such as support for endocrine cells, intercellular communication, phagocytosis and modulation of the endocrine and immune responses. We have shown that the FS cell shape responds to the hormonal milieu. Because FS cells are the target of cytokines, here we studied the effect of pro-inflammatory cytokines on their morphology. We used a stable mouse cell line, the TtT/GF cells, which show morphological and biochemical features of normal FS cells. TtT/GF cells were treated with the pro-inflammatory cytokines TNFα (20 ng/ml), IL-1β (10ng/ml) and IFNγ (10U/ml) for increasing periods of time (0 to 96hs). The shape of the cells, the reorganization of the actin cytoskeleton and changes in the localization and expression of actin-binding proteins were evaluated by fluorescence microscopy and Western blot. Treatment with TNFα or IL1-β but not INF-γ induced apoptosis of TtT/GF cells. The cells rounded up, detached and the nuclei showed condensed chromatin. Twenty % of TtT/GF cells evidenced signs of apoptosis after 24hs-treatment with TNFα or IL-1β. By 96hs the percentage increased to 50%. Caspase 8 was activated by 48hs of treatment with TNFα or IL-1β while caspase 3 was activated by 72hs. In immunofluorescence, incubation with TNFα or IL-1β for 72hs caused the loss of proteins involved in focal contacts such as α-actinin, vinculin and paxillin. In addition, cytokines caused the cleavage of the actin-anchoring protein, spectrin. The results show that 1) the pro-inflammatory cytokines TNFα and IL-1β but not IFN-γ caused changes in the FS cell morphology that were related to the induction of apoptosis, and 2) actin-anchoring proteins were down regulated and/or cleaved during this process. Supported by NSERC-Canada.

## Actin-Associated Proteins I (151-171)

**Actin Capping Protein Alpha Maintains *Vestigial*-expressing Cells in the *Drosophila* Wing Disc Epithelium**

F. Janody,[1] J. Treisman[2]; [1]LGPD, Developmental Biology Institute of Marseille, Marseille, France, [2]Department of Cell Biology, Skirball Institute, NYU School of Medicine, New York, NY

*Drosophila* appendages develop from larval imaginal discs, which are composed of a pseudostratified columnar epithelium apposed to the thin squamous peripodial membrane. Patterning and growth of these structures are established by a series of complex regulatory interactions among transcription factors and morphogens. In a mosaic genetic screen, we identified mutations in the *capping protein alpha (cpa)* and *twinstar (tsr)* genes, which encode Actin Binding Proteins (ABP). Cpa binds to the fast growing ends of actin filaments, blocking further addition of subunits. *tsr* encodes the Cofilin homologue, which severs actin filaments and promotes depolymerization. Interestingly, clones mutant for *cpa* cannot be recovered in the epithelium of the wing pouch territory. Mutant cells undergo an epithelial to mesenchymal transition, extrude basally and die by apoptosis. However, *cpa* mutant cells persist in the epithelium of the remainder of the wing disc. In contrast, *tsr* mutant clones proliferate and survive equally well in all regions of the wing disc. Both *cpa* and *tsr* restrict actin filament polymerization throughout the cell cortex, indicating that excessive actin polymerization is not sufficient to explain the cpa mutant phenotype; rather, *cpa* is specifically required to maintain epithelium integrity in the wing pouch territory. The expression of *vestigial (vg), which* promotes growth of the wing pouch epithelium, is not affected in *cpa*

mutant clones. Misexpression of vg in *cpa* mutant cells is sufficient to cause them to extrude basally and die in all regions of the wing disc. This shows that *vg* controls the requirement for *cpa* and suggests that regulation of the actin cytoskeleton by ABP has distinct effects on different epithelial territories.

152

**Binding of V-1 to Actin Capping Protein**

S. Ghosh, D. Sept; Biomedical Engineering, Washington University, St. Louis, MO

V-1 (also known as myotrophin) is a 12 kDa protein consisting of three ankyrin repeats. Proteomic studies have revealed that V-1 interacts directly with capping protein (CP). Interestingly, unlike other CP regulators such as $PIP_2$ and CARMIL, V-1 cannot uncap already capped barbed ends but can only inhibit capping. Deletion mutants have shown that the C-terminus of the ß-subunit of CP plays an important role in the binding of V-1 to CP. However the molecular details of the interaction of V-1 with CP are unknown. Through the use of molecular dynamics and molecular docking simulations, we have developed a model of how V-1 binds CP. Our results indicate that V-1 binds both to the C-terminus tentacle of the ß-subunit of CP and the body of CP reducing the mobility of the tentacle and thus reducing the affinity of CP for the barbed end of actin filaments. These results agree well with the observation that the beta tentacle is critical for CP function.

153

**Binding of PI(4,5)$P_2$ to Capping Protein**

M. E. McCully, D. Sept; Biomedical Engineering and Center for Computational Biology, Washington University, St. Louis, MO

Phosphatidylinositol-4,5-biphosphate (PIP2), a lipid present in the cell membrane, has been found to regulate actin filament polymerization by binding to actin-regulating proteins. In the presence of PIP2, capping protein can be removed and inhibited from further capping, allowing the free barbed end to grow against the cell membrane. Experimental data has suggested a binding location for PIP2 in the C-terminal region of the α-subunit, but the molecular details of the interaction remain unknown. Through a combination of molecular dynamics and molecular docking simulations, a binding location was identified at the base of the α-C-terminus. Our results suggest specific interactions between the negatively charged phosphate groups of PIP2 and the three positively charged residues: Lys 256 and Arg 260 from the α-subunit and Arg 255 from the β-subunit. Experiments introducing point mutations at these residues have confirmed this binding location.

154

**Characterization of a Low Abundant Profilin Isoform in *Dictyostelium discoideum***

R. Arasada,[1] A. Gloss,[1] J. Faix,[1] A. A. Noegel,[2] M. Schleicher[1]; [1]A.-Butenandt Institute for Cell Biology, Ludwig-Maximilian University Munich, Munich, Germany, [2]Center for Biochemistry, Medical Faculty, University of Cologne, Cologne, Germany

Profilins are small and ubiquitous G-actin binding proteins that are necessary for the turnover of actin filaments. Profilin forms a 1:1 complex with ADP-actin, exchanges ADP with ATP thus regenerating the pool of ATP-actin needed for polymerization. Apart from actin, it also binds to phosphatidylinositols and many other proteins with stretches of proline residues. These include also actin binding proteins such as the Arp2/3 complex, formins, and VASP Like most of the eukaryotic organisms tested, *Dictyostelium discoideum*, a facultative single celled social amoeba, contains two profilin isoforms (Haugwitz *et al*., 1994, Cell 79:303-14). The completed genome sequence of *D. discoideum* (Eichinger *et al*., 2005, Nature 435:43-57) revealed a third profilin isoform. Recombinant profilin III behaves nearly identical to the other two profilin isoforms *in vitro*, and rescues the phenotype of pI/II minus cells when overexpressed. Interestingly, profilin III is uniformly expressed throughout development, and about 200-fold less abundant than profilin I and II. This was also the reason that the protein could not be detected in pI/II-minus cells. Immunolocalization studies using profilin III specific polyclonal antibodies in vegetative cells show an overall distribution and sometimes a strong enrichment at the tips of filopodia. In contrast to profilin I or II, the third profilin isoform interacts with VASP in a yeast two hybrid assay. To further characterize the function of profilin III, we generated profilin III null mutants. Null mutants show reduced efficacy in migration towards a cAMP source during chemotaxis whereas development is not affected. The data suggest that this low abundant profilin isoform *in vivo* is not primarily an actin sequestering protein but affects cell migration during chemotaxis as a regulator in signal transduction.

155

**Competitive Biochemical Interactions of Myotrophin/V-1 with Actin Capping Protein and NF-kappa B**

N. Bhattacharya, J. A. Cooper; Cell Biology, Washington University School of Medicine, St. Louis, MO

In cells, nuclear factor kappa B (NF-κB) signaling can accompany and depend on actin assembly. Actin capping protein (CP) regulates actin assembly and cell motility. The protein V-1 / myotrophin interacts with CP and with NF-κB. In the present study, we demonstrate that V-1 binds directly to CP, with a Kd of ~ 100 nM. V-1 binding inhibited the ability of CP to cap the barbed ends of actin filaments, but did not cause uncapping. The C-terminal tentacle of the CP beta subunit, which is known to bind to actin, was necessary and sufficient to bind V-1. Two loops of V-1, which extend out from the α-helical backbone of this ankyrin repeat protein, were necessary for V-1 to bind CP. Parallel computational studies determined a bound conformation of the beta tentacle with V-1 that is consistent with these findings. We found that V-1 binds directly to NF-κB, with differential affinity in the submicromolar range for the p50 homodimer, p65 homodimer and p50 / p65 heterodimer forms. NF-κB and CP compete with each other for binding to V-1. These interactions provide a biochemical pathway connecting actin assembly with NF-κB signaling, which may have physiological relevance.

156

**Mammals Have Two Twinfilin Isoforms; Twinfilin-1 and Twinfilin-2**

E. M. Nevalainen,[1] M. Vartiainen,[2] T. Matilainen,[1] M. Salminen,[1] A. Braun,[3] R. Fässler,[3] P. Lappalainen[1]; [1]Institute of Biotechnology, Helsinki, Finland, [2]Cancer Research UK, London Research Institute, London, United Kingdom, [3]Max Planck Institute for Biochemistry, Martinsried, Germany

Twinfilin is a highly conserved actin monomer-binding protein that regulates cytoskeletal dynamics in organisms from yeast to mammals. Twinfilin binds ADP-G-actin with a higher affinity than ATP-G-actin and efficiently inhibits actin filament assembly *in vitro*. In addition to actin monomers, twinfilin also binds capping protein and this interaction may localize twinfilin -actin monomer complexes to the sites of rapid actin

filament assembly in cells. Unlike yeasts, worms and flies, which have only one twinfilin protein, we identified two twinfilin isoforms, twinfilin-1 and twinfilin-2, from mammals. The two mouse twinfilin isoforms bind actin monomers and capping protein with similar affinities to each other, but show cell-type specific expression patterns. Twinfilin-1 is the major isoform in developing embryos and in adult mouse non-muscle cells, whereas twinfilin-2 is the predominant isoform in differentiated muscle cells. Furthermore, our cell biological studies suggest that the subcellular localizations of twinfilin-1 and twinfilin-2 are regulated through distinct signaling pathways. To reveal the biological roles of the two mammalian twinfilins, we have generated knock-out mice for both twinfilin isoforms through targeted disruption of the twinfilin-1 and twinfilin-2 genes. These knock-outs will help to resolve the role of twinfilin in actin dynamics in mammalian cells as well as their specific roles in various actin-dependent cellular and developmental processes in mammals.

157

**Molecular Architecture of Twinfilin and its Actin-Monomer Binding Regions**

V. O. Paavilainen, M. Hellman, M. Koskinen, P. Permi, A. Annila, P. Lappalainen; Institute of Biotechnology/University of Helsinki, Helsinki, Finland

Actin machinery is regulated by a variety of actin regulating proteins. Of these only six actin-monomer binding proteins are conserved in eukaryotes. They include the profilin, ADF/cofilin, twinfilin, SRV2/CAP, WASP/WAVE and verprolin/WIP -proteins. Twinfilin is a novel and ubiquitous actin-monomer binding protein composed of two ADF-H (Actin Depolymerizing Factor -Homology) domains, separated by a short linker and followed by a 35-residue C-terminal tail region. Twinfilin binds the actin monomer with a 1:1 stoichiometry, inhibits the nucleotide exchange on actin and also inhibits monomer assembly into filaments. Twinfilin appears to first associate with the actin monomer via its' N-terminal 'low-affinity' ADF-H domain, after which it is transferred to the 'high-affinity' C-terminal ADF-H domain. The depletion of twinfilin in S.cerevisiae results in defects in the bipolar budding pattern and in rough eye phenotype and aberrant bristle morphology in Drosophila melanogaster. These phenotypes arise because of uncontrolled actin polymerization in the absence of twinfilin. To properly understand the molecular mechanisms of twinfilins' function, it was imperative to gain structural information of the twinfilin molecule. For this purpose we had earlier solved the crystal structure of the N-terminal ADF-H domain, and have now solved the C-terminal domain structure by NMR methods. The new structure is highly similar to the N-terminal ADF-H domain and other known ADF-H domains. We are currently confirming the actin-monomer binding site of twinfilins' C-terminal ADF-H domain by systematic mutagenesis. The two structures combined with biochemical data will enable us to better understand twinfilins' role as an essential regulator of actin dynamics.

158

**Twinfilin Severs Actin Filaments and Promotes Actin Turnover In Vivo**

J. B. Moseley,[1] K. Okada,[1] D. R. Kovar,[2] H. I. Balcer,[1] T. D. Pollard,[2] B. L. Goode[1]; [1]Biology, Brandeis University, Waltham, MA, [2]Molecular, Cellular and Developmental Biology, Yale University, New Haven, CT

Working in concert multiple actin binding proteins regulate the dynamic turnover of actin networks. Until now, only one well-conserved factor has been identified that directly promotes actin filament disassembly, ADF/cofilin. Here, we demonstrate a related cellular function for the highly conserved actin binding protein twinfilin, which until now was thought to function primarily as a monomer sequestering protein. Twinfilin localizes *in vivo* to sites of rapid actin turnover, including cortical patches in yeast and membrane ruffles in mammalian cells. We show that purified budding yeast twinfilin (Twf1) actively promotes filament disassembly in bulk kinetic assays and dramatically reduces average filament length in seconds. Further, we use real-time evanescent wave fluorescence microscopy to show that Twf1 severs individual actin filaments to generate free filament barbed ends. Consistent with these biochemical functions, we demonstrate that Twf1 promotes actin filament turnover in live yeast cells. Previous work has demonstrated that capping protein (Cap1/2) binds directly to Twf1 *in vitro* and recruits Twf1 to sites of rapid actin turnover *in vivo.* However, no specific function has yet been ascribed to this physical interaction. We demonstrate that Cap1/2 inhibits Twf1 severing activity. Further, filament severing and depolymerization by Twf1 are tightly regulated *in vitro* by pH. Thus, twinfilin defines a novel class of filament severing and depolymerization protein that is subject to regulation by both pH and capping protein. These results suggest that twinfilin coordinates multiple key aspects of actin dynamics--filament severing, filament capping, and monomer sequestering--at sites of rapid actin turnover *in vivo*.

159

***Caenorhabditis elegans* Kettin, a Large Immunoglobulin-like Repeat Protein, Binds to Filamentous Actin and Is Involved in Actin Organization in Muscle**

S. Ono, K. Mohri, K. Ono; Pathology, Emory University, Atlanta, GA

Kettin is a large actin-binding protein with immunoglobulin-like (Ig) repeats, which is associated with the thin filaments in arthropod muscles. Here, we report identification of kettin in the nematode *Caenorhabditis elegans* and its functional characterization. We found that MH44, one of the monoclonal antibodies that were raised against *C. elegans* muscle proteins [G. R. Francis and R. H. Waterston. (1985) *J. Cell Biol.* 101: 1532-1549], specifically reacts with kettin (Ce-kettin). We determined the entire cDNA sequence of Ce-kettin that encodes a protein of 472 kDa with 31 Ig repeats. Arthropod kettins are splice variants of much larger connectin/titin-related proteins. However, the gene for Ce-kettin (*ketn-1*) is independent of other connectin/titin-related genes. Ce-kettin localizes to the thin filaments near the dense bodies in both striated and non-striated muscles. The C-terminal four Ig repeats were sufficient for binding to actin filaments *in vitro*, whereas the adjacent non-Ig region augmented the actin-binding activity. RNA interference of Ce-kettin caused partial disorganization of the actin filaments in body wall muscle. These results indicate that kettin is an important regulator of actin organization and suggest that kettin might be functionally homologous to vertebrate cytoskeletal proteins with Ig repeats, such as palladin, myopalladin, and myotilin.

160

**Calcium/Calmodulin Dependent Protein Kinase-II Interacts with Flightless-I in Embryonic Fibroblasts**

M. E. Seward,[1] J. H. Moxley,[1] M. W. Mayhew,[2] A. F. Horwitz,[2] R. M. Tombes[1]; [1]Department of Biology, Virginia Commonwealth University, Richmond, VA, [2]Department of Cell Biology, University of Virginia, Charlottesville, VA

CaMK-II is a highly conserved and broadly expressed $Ca^{2+}$/calmodulin-dependent protein kinase. CaMKII is believed to be involved in many cellular processes including synaptic plasticity, gene expression, cell cycle progression, cell adhesion, and motility. In an effort to identify binding partners potentially regulated by CaMK-II in motile fibroblasts, mass spectrometry was performed on immunopurified FLAG-tagged isozymes of CaMK-II (α, β, $\delta_c$, and $\delta_e$). Identified binding partners included not only CaMK-II and calmodulin, but also myosin subunits, cofilin, tropomodulin-3, β-tubulin, β- and γ-actin, flightless-I (Fli-I), and LRRFIP (a Fli-I binding protein). Of particular interest is Fli-I, which is a gelsolin-related actin-binding protein Fli-I and was identified in association with both full length CaMK-II and with CaMK-II lacking the catalytic domain. Fli-I is a developmentally essential 145kDa protein that is conserved throughout all metazoans. It is known to shuttle between the nucleus and the cytosol, where it is involved in regulating actin filaments. The interaction of endogenous CaMK-II with Fli-I was shown through reciprocal immunoprecipitations in differentiating mouse neurons as well as in mouse and human embryonic fibroblasts. For instance Fli-I IPs contained CaMK-II, as determined through both activity assays and immunoblots. Similarly, CaMK-II IPs contained the expected 145kDa band when blotted for Fli-I. These findings indicate that Fli-I associates with CaMK-II through either its variable or association domain and raises the possibility of CaMK-II dependent regulation of Fli-I.

161

**Alternative Exon Choice in the Gamma Tropomyosin (γ-Tm) Gene is Not Absolutely Programmed in Different Cell Types**

J. Hook,[1,2] G. Schevzov,[1,2] B. Vrhovski,[1] F. Lemckert,[1] T. Borovina,[1] E. Hardeman,[3] P. Gunning[1,2]; [1]Oncology Research Unit, The Children's Hospital at Westmead, Westmead NSW, Australia, [2]Discipline of Paediatrics and Child Health, University of Sydney, Sydney NSW, Australia, [3]Muscle Development Unit, Children's Medical Research Institute, Westmead NSW, Australia

The actin filament system is fundamental to cellular functions including regulation of shape, motility, cytokinesis, intracellular trafficking and tissue organisation. Tropomyosins (Tm) are highly conserved actin binding proteins differentially affecting stability and function of actin filaments. The mammalian Tm family consists of four genes; α-Tm, β-Tm, γ-Tm and δ-Tm. Multiple Tm isoforms are generated by alternative splicing, and expression of these isoforms is highly regulated during development. γ-Tm nonmuscle gene products (Tm5 NM1-11) are involved with the establishment of neuronal polarity, axon outgrowth and maturation in brain. Alternative exon choice in γ-Tm products can lead to intracellular targetting to diverse locations such as growth cones versus axons in neurons and Golgi versus stress fibres in fibroblasts. Using the γ-Tm gene, we tested mechanisms that underpin alternative exon choice in development. We first removed the amino-terminal exon 1b to ablate all isoforms. Genetic analysis failed to identify homozygous knockout mice, indicating γ-Tm gene products are essential for embryonic development. We next restricted γ-Tm gene product repertoire and forced alternative exon selection by removing carboxy-terminal exons 9c and 9d. Mice lacking exon 9c show a normal phenotype with elevated expression of products from exon 9a in specific tissues. Mice lacking exon 9d display compensating use of exons 9a and 9c, however no compensation for loss of 9d is observed in embryonic stem cells. We conclude that selection of alternative exons is not absolutely fixed and that compensatory use of alternative exons can differ between cell types.

162

**Genetic and Biochemical Analyses Predict a Mechanism for Aip1p in Actin Filament Disassembly**

M. G. Clark, B. Haarer, D. C. Amberg; Biochemistry and Molecular Biology, SUNY Upstate Medical University, Syracuse, NY

Regulation of the organization and function of the actin cytoskeleton requires rapid filament turnover and modulation of turnover rates by accessory factors. Biochemical analyses indicate that cofilin and Aip1p cooperate to accelerate actin dynamics. These conserved proteins co-localize in cortical actin networks from diverse organisms. Cofilin has long been known to promote depolymerization of actin filaments by accelerating pointed-end disassembly and by exhibiting a weak filament-severing activity. Aip1p dramatically enhances disassembly of actin filaments in a cofilin-dependent manner by capping the barbed ends, activating severing, or a combination of both. PCR-induced mutagenesis has allowed us to identify active sites on Aip1p required for the actin and cofilin interactions, leading to a model for the ternary complex formed by Aip1p, cofilin, and actin. Biochemical and genetic analyses of these mutants have been conducted in an effort to elucidate the mechanism of Aip1p's activity by identifying mutations that disrupt the ability of Aip1p to participate in severing- and/or capping-specific filament disassembly. In addition, we have combined an *aip1Δ* allele with a sub-array of gene deletion alleles, whose gene products are known to localize to cortical actin patches in yeast. By identifying synthetic growth defects that occur when *aip1Δ* is combined with other gene deletions alleles, we were able to make inferences regarding specific physiological roles for Aip1p in the cell. Our findings suggest that Aip1p participates in a specific step of the endocytic internalization process.

163

**AFAP-110: A Lyn Kinase Activator**

I. H. Qazi, D. C. Flynn; Mary Babb Randolph Cancer Center, West Virginia University, Morgantown, WV

In many invasive or metastatic cancers, activated c-Src kinase is found at elevated levels and causes a transformed phenotype where there is a disruption of the actin cytoskeleton, reduced growth requirements, etc. In many cases increased activity is due to enhanced activation of c-Src by interacting proteins rather than mutations or an increase in transcription or translation. AFAP-110 is an adapter protein that was first identified as a SH3/SH2 binding partner for activated c-Src. A dominant positive form of AFAP-110 (AFAP-$110^{\Delta L.zip}$) helped demonstrate its intrinsic ability to activate c-Src via domain interactions and lead to subsequent cellular transformation. Due to high sequence and structural homology between Src family members it is hypothesized that the AFAP-110 could similarly activate Lyn kinase. While expression of Lyn is restricted primarily to hematopoietic tissues, recent work on tumor samples such as glioblastoma multiforme and hormone refractory prostate cancers implicate Lyn as a culpable player in their carcinogenesis. Here we demonstrate that the SH3 domain of Lyn was sufficient to affinity absorb GFP-tagged AFAP-110 from fibroblast cell lysates and the two proteins interact when co-transfected into epithelial and fibroblast cells. Both stable and transient transfections of Lyn and AFAP-$110^{\Delta L.zip}$ into SYF cells seems to activate Lyn in a similar pattern to that of c-Src. These patterns included changes in the actin cytoskeleton, increased cellular tyrosine phosphorylation, the redistribution of cellular cortactin, and the formation of podosomes structures. These findings may have clinical relevance in tumors where AFAP-110 may receive upstream signals to activate Lyn kinase.

164

**Caldesmon is an Integral Component of Podosomes in Smooth Muscle Cells**

B. A. Webb, R. Eves, A. S. Mak; Biochemistry and Protein Function Discovery Program, Queen's University, Kingston, ON, Canada

Podosomes are highly dynamic, actin-based structures commonly found in motile and invasive cells such as macrophages, osteoclasts, and vascular smooth muscle cells. Here we investigated the role of caldesmon, the actin-binding protein, in the formation of podosome in smooth muscle A7r5 cells induced by phorbol-ester, PDBu. We found that endogenous l-caldesmon, which was normally localized to actin-stress fibers and membrane ruffles, was recruited to PDBu-induced podosomes. Over-expression of l-caldesmon caused dissociation of actin-stress fibres and disruption of focal adhesion complexes, but did not lead to formation of podosomes. Treatment of the caldesmon-transfected cells with PDBu induced the formation of caldesmon-enriched podosomes. Transiently transfected N-terminal fragment of l-caldesmon, Cad40, containing the myosin-binding sites, was not present in PDBu-induced podosomes; whereas the C-terminal fragment, Cad39 housing the binding sites for actin, tropomyosin and calmodulin, was translocated to podosomes. The caldesmon mutant, CadCamAB, which does not interact with $Ca^{2+}$-calmodulin, was not recruited to PDBu-induced podosomes. These results suggest that l-caldesmon is required for PDBu-induced podosome formation and is an integral part of the core actin column. The calmodulin-binding domain at the C-terminal half of l-caldesmon is essential for the translocation of l-caldesmon to the podosomes.

**Pyrin, Product of the MEFV Locus, Interacts with Actin Polymerizing Machinery**

A. L. Waite,[1] P. Schaner,[2] N. Richards,[1] B. Balci,[1] D. L. Gumucio[1,2]; [1]Cell & Developmental Biology, University of Michigan, Ann Arbor, MI, [2]Cell & Molecular Biology, University of Michigan, Ann Arbor, MI

Familial Mediterranean Fever (FMF) is an autoinflammatory disorder characterized by attacks of fever with pain and neutrophil infiltration localized to the abdomen, chest, skin, or joints. FMF is caused by mutations in the *MEFV* locus, the protein product of which is pyrin. Pyrin is expressed primarily in neutrophils and monocytes. Exon 1 of pyrin encodes a pyrin domain (PyD), which in other proteins is associated with inflammation and apoptosis. In monocytes, pyrin is primarily cytoplasmic and localizes to leading edge lamellipodia, a site of active actin polymerization. We confirmed that pyrin is localized to polymerizing actin using the *Listeria* rocket assay. Mutant pyrin also localizes to rockets. In a yeast two-hybrid screen, we identified PSTPIP1, a known actin-associated protein, as a pyrin-binding protein. Though we hypothesized that PSTPIP1 could be responsible for recruiting pyrin to *Listeria* rockets, we found that PSTPIP1 does not associate with rockets. Thus, another factor must be responsible for the recruitment of pyrin to sites of actin polymerization. We therefore tested whether pyrin binds to any of eight proteins known to be involved in actin polymerization (actin, Arp3, VASP, α-actinin, profilin, cofilin, gelsolin, and capping protein). We found that wild-type pyrin binds to both cofilin and gelsolin. Recently it was discovered that these two proteins are involved in modulating the release of DNase I from actin (Chhabra, 2005), and therefore may mediate the change in a cell from a state of migration to one of apoptosis. Mutant pyrin does not bind to gelsolin but binds to capping protein. This may indicate a change in the essential function of the protein and lead to a condition where inflammatory cells migrate more efficiently but cannot die.

166

**Identification of a Human Mps1 Interacting Protein**

C. P. Mattison, M. Winey; MCD Biology, CU-Boulder, Boulder, CO

Defects in centrosome duplication lead to chromosome instability, aneuploidy, and are found in many types of tumor cells. The mono-polar spindle 1 (Mps1) protein kinase is highly conserved among eukaryotes, and recent studies have shown that human Mps1 (hMps1) is involved in the duplication of centrosomes. To better understand the role of hMps1 in centrosome duplication I performed a two-hybrid experiment with the amino-terminus of hMps1. From this screen I have identified the hMps1 interacting protein 1 (MIP1) gene. The MIP1 gene is conserved among vertebrates and encodes a protein with a large central coiled coil domain and a calponin homology domain at the carboxy terminus. Results with a MIP1 clone fused to Green Fluorescent Protein (GFP) indicate that MIP1 protein localizes to actin filaments in several human cell types. In addition, MIP1 protein binds hMps1 in vitro, and is an in vitro substrate for hMps1. I plan to determine whether MIP1 plays a role in centrosome duplication, and how the interaction with hMps1 contributes to this role. hMps1 has also been shown to be important for the spindle assembly checkpoint, cytokinesis and cell cycle progression. Based upon the sequence and localization of MIP1 to actin filaments, it may be involved in some aspect of cytokinesis. Future experiments will focus on defining the interaction between hMps1 and the AMIP protein in human cells.

**The Actin Binding Property of SWAP-70, a Mediator of Membrane Ruffling after Growth Factor Stimulaion**

S. Ihara, Y. Fukui; Applied Biological Chemistry, University of Tokyo, Tokyo, Japan

SWAP-70 is a PH (pleckstrin homology) domain containing protein, which exhibits binding ability to $PIP_3$, a product of PI3-kinase. It has been shown that SWAP-70 is required for efficient membrane ruffling after growth factor stimulation. We previously described that the extreme C-terminal region of SWAP-70 binds to F-actin and that a mutant SWAP-70 lacking the region behaves as a dominant negative reagent. These results suggest that the direct binding of SWAP-70 to F-actin is required for the membrane ruffling. In this study, the property of actin binding activity was further explored. When non-muscle actin was used in co-sedimentation assay, C-terminal region of SWAP-70 exhibited a binding activity much stronger than that to muscle F-actin with an approximately 1:1 stoichiometry in saturation. Therefore, the binding of SWAP-70 to F-actin is isospecific. A mutant SWAP-70 lacking the C-terminal region still exhibited a binding activity, but it was not isospecific. We found that the PH domain sedimented with either type of F-actin at the same extent, suggesting that the PH domain is an additional F-actin binding domain. Although the significance of this binding activity remains unclear, it is interesting to speculate that the two F-actin binding domains play different roles in F-actin organization.

**The Nck-Interacting Kinase NIK Phosphorylates ERM Proteins: A Mechanism for Lamellipodia Formation by Growth Factors**

M. Baumgartner,[1] E. M. Blackburn,[2] A. Sillman,[1] J. Srivastava,[1] J. W. Schilling,[2] J. H. Wright,[2] D. L. Barber[1]; [1]Cell and Tissue Biology,

University of California, San Francisco, San Francisco, CA, [2]Sugen, South San Francisco, CA
The mammalian Ste20-like Nck-interacting kinase NIK and its orthologs Misshapen in *Drosophila* and Mig-15 in *Caenorhabditis elegans* have a conserved function in regulating cell morphology. NIK substrates that control cell morphology, however, have not been clearly identified. We now report that the ERM proteins ezrin, radixin, and moesin are substrates for NIK, and that NIK phosphorylation of ERM proteins is necessary for growth factor-induced lamellipodia formation. ERM proteins regulate cell morphology and plasma membrane dynamics by anchoring actin filaments to integral plasma membrane proteins. ERM proteins are activated by phosphorylation of a conserved C-terminal threonine that induces a conformational change promoting their binding to F-actin. *In vitro* assays show that purified NIK phosphorylates the conserved C-terminal threonine in ERM proteins (T567 in ezrin). Additionally, NIK directly binds the N-termini of ERM proteins and the ERM-binding site is within the proximal 33 amino acids of the NIK C-terminal regulatory domain. In fibroblasts, expression of a truncated NIK containing only the N-terminal kinase domain and the ERM-binding domain was sufficient to increase phosphorylation of ERM proteins. NIK and ERM proteins co-localize at the distal margin of lamellipodia, and in fibroblasts and epithelial cells increased phosphorylation of ERM proteins in lamellipodia by platelet-derived growth factor and epidermal growth factor is inhibited by expression of kinase-inactive NIK-D152N. In contrast, NIK-D152N has no effect on increased phosphorylation of ERM proteins by thrombin. Live cell imaging shows that lamellipodia extension in response to growth factors is inhibited by expression of NIK-D152N or ezrin-T567, but not by expression of wild-type NIK or ezrin. Hence, direct phosphorylation of ERM proteins by NIK constitutes a signaling mechanism controlling growth factor-induced membrane protrusion and cell morphology. Supported by NIH grant GM47413.

**Cell Swelling Causes Actin Reorganization and Recruitment of the Actin Binding Protein Moesin in Membrane Protrusions in Collecting Duct Principal Cells**

G. Tamma, M. Svelto, G. Valenti; Department of General and Environmental Physiology, University of Bari, Bari, Italy
Cell swelling causes actin cytoskeleton remodelling associated with the modification of cell architecture. The ERM family (ezrin, radixin, moesin) proteins crosslink the actin filaments and plasma membrane and are important signal transducers during actin reorganization. The actin cytoskeleton is a dynamic structure regulated by the monomeric G protein of the Rho family. Moesin plays a key role in actin remodelling by binding actin filaments through its C-terminal domain and RhoGDI through its N-terminal domain. In collecting duct CD8 cells hypotonicity-induced cell swelling resulted in a deep actin reorganization, consisting in loss of stress fibers and the formation of F-actin patches in membrane protrusions. Immunofluorescence studies revealed that actin and moesin co-localized in membrane protrusions. TritonX-100 extraction procedure, which preserves the cytoskeleton and the cytoskeleton-associated proteins, confirmed that cell swelling increased the interaction between actin and moesin. Hypotonic stress caused recruitment of moesin in cell cortex and a transition of moesin from the oligomeric to monomeric functional conformation. In its monomeric form, moesin can bind interacting proteins when the C and N terminal domain are exposed and this conformation is stabilized by phosphorylation of a conserved threonine in the C-terminal domain by PKC or Rho kinase. Interestingly, exposure of CD8 cells to hypotonic stress increased the amount of threonine-phosphorylated moesin. While PKC inhibitor, Ro-31-8220, did not affect moesin phosphorylation, Rho kinase inhibitor Y27632 decrease the basal level of the phosphorylated moesin but did not affect the hypotonicity-induced increase of phosphorylated moesin. Altogether the data represent the first evidence that hypotonicity-induced actin remodelling is associated with moesin recruitment at the cell border and interaction with actin in a phosphorylated state.

170

**EGFP-CALI of Mena Changes Lamellipodial Dynamics**

E. Vitriol,[1] J. E. Bear,[1,2] K. Jacobson[1,2]; [1]Cell and Developmental Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Lineberger Comprehensive Cancer Center, University of North Carolina at Chapel Hill, Chapel Hill, NC
Chromophore assisted light inactivation (CALI) is a tool for local and instantaneous loss of protein function. CALI first requires the attachment of a chromophore to a target protein; inactivation is then mediated by the photogeneration of reactive oxygen species (ROS). The short half-life of ROS largely limits inactivation to the targeted protein. Enhanced green fluorescent protein can be used for CALI and has the advantage of being both genetically encoded and covalently linked to the protein target of interest. Here we tested EGFP-CALI in a well-defined live cell system: the effect of Mena/VASP proteins on lamellipodial dynamics. When Mena/VASP members are present at the leading edge protrusions emerge rapidly and are transient; by contrast, when Mena/VASP members are absent from the leading edge the protrusions emerge at a slower velocity and become more persistent (Bear et al. *Cell*. 109(4):509-21), resulting in faster migration rates (Bear et al. *Cell*. 101(7):717-28). To perform EGFP-CALI of Mena, we used Mena/VASP -/- fibroblasts ($MV^{D7}$ cells) rescued with EGFP-Mena; using rescued knockout cells allowed us to avoid a potential loss of the CALI phenotype by the presence of endogenous, unlabeled protein. Employing kymograph analysis we show that local irradiation of EGFP-Mena at the leading edge significantly reduces protrusion velocity and increases protrusion persistence. This effect is reversible, with lamellipodial dynamics returning to their original state following fluorescence recovery into the irradiated region. Irradiation of non-rescued $MV^{D7}$ cells or $MV^{D7}$ cells expressing EGFP alone did not change leading edge dynamics. This work was supported by the NIH Cell Migration Consortium (GM 64346).

**Investigation of Expression and Biological Roles of the F-Actin Associated Protein Coronin 3**

C. S. Clemen, A. Rosentreter, A. Hasse, Z. Spoerl, M. Stumpf, A. A. Noegel; Institute of Biochemstry I, Medical Faculty, University of Cologne, Cologne, Germany
Coronin proteins belong to the fundamental and versatile WD40-repeat domain proteins. All coronin proteins possess a conserved basic N-terminal motif and three to ten WD40-domain repeats clustered in one or two core domains. Generally, they are mainly found at the submembraneous area, bind F-actin in vitro, and are implicated in eukaryotic F-actin dynamics in vivo or they have a role in vesicular transport. Coronin 3 is a widely expressed 57 kDa protein being abundant in the central nervous system. Its N-, WD40-, and partially the C-domain are highly conserved in mammals and within different members of the protein family. The very C-terminal coiled-coil domain mediates the formation of trimers, the entire C-terminus binds to and cross-links F-actin and confers membrane association in vitro and in vivo. Cytosolic coronin 3 shows phosphorylation

which most likely regulates the subcellular localization and biological activity. Transfection studies employing various coronin 3 domain constructs revealed that for its localization and biological function an interaction of N- and C-termini are required as well as regulatory effects mediated by the central WD40-domain. The protein is involved in processes like neurite outgrowth, noradrenaline secretion, wound healing, cytokinesis, proliferation, and cell motility. During early murine brain development and the first postnatal stages all areas of the brain express coronin 3. Postnatally, the expression in the grey matter decreases along with neuronal differentiation, except for hippocampal pyramidal and dentate gyrus neurons, and cerebellar Purkinje cells, while levels in the white matter increase in the course of myelination. Our results favor a major role for coronin 3 in cellular processes depending on F-actin dynamics.

## Unconventional Myosins (172-197)

172

### The Globular Tail Domain Regulates the Enzymatic Activity of Myosin V

K. Thirumurugan,[1] P. J. Knight,[1] J. A. Hammer,[2] J. R. Sellers[3]; [1]School of Biomedical Sciences, University of Leeds, Leeds, United Kingdom, [2]Laboratory of Cell Biology, National Heart, Lung and Blood Institute, Bethesda, MD, [3]Laboratory of Molecular Physiology, National Heart, Lung and Blood Institute, Bethesda, MD

Myosin V is a processive motor that translocates various cargo along actin filaments. It has two heads with neck domains containing 6 IQ-motifs that bind calmodulin. The actin-activated MgATPase of tissue purified myosin V is strongly regulated by calcium. In the absence of calcium the ATPase activity is low and the molecule exists in a compact, folded state that sediments at 14S in the ultracentrifuge. Addition of micromolar levels of calcium activates the ATPase activity 10-30 times and is associated with unfolding of the molecule (11S). EM observation of negatively stained myosin V in the absence of calcium shows a compact, isosceles-triangular structure (1). Using single particle image processing techniques we find that the long sides of the triangular structure correspond to the elongated neck domains of myosin V and that the shorter base of the triangle is formed by the motor domains interacting with the globular tail domain (GTD). A segment of the coiled-coil tail is seen running from the junction of the two necks to the GTD. This structure is consistent with our observation that baculovirally-expressed myosin V HMM which retains the two-headed structure, but lacks the GTD is constitutively active regardless of calcium concentration. Moreover, we find that a GST-GTD fusion protein inhibits the actin-activated MgATPase of myosin V HMM to about 25% of its maximal activity with a Ki of about 1 uM. This is consistent with the model proposed above where, in the absence of calcium and cargo, myosin V folds into a compact structure where the globular tail domains directly bind the motor domains to stabilize an inhibited structure. 1. Wang et al. J.Biol.Chem. 279: 2333-2336, 2004.

### Dynamics and Distribution of Myo5c, a Class V Myosin of Epithelial Cells

D. T. Jacobs, R. E. Cheney; Cell and Molecular Physiology, University of North Carolina-Chapel Hill, Chapel Hill, NC

Class V myosins are hypothesized to function as actin-based organelle transporters. The third member of the class V myosin in mammals, myosin 5c, is expressed chiefly in epithelial cells (Rodriguez and Cheney, JCS, 115:991-1004). Our results show Myo5c is abundant in exocrine tissues such as the lacrimal gland, pancreas, and mammary gland. Immunohistochemistry reveals that Myo5c localizes to the apical domain of the polarized epithelial cells in these tissues. We are using MCF-7 and HeLa cells as model systems to identify the organelles and trafficking pathways associated with Myo5c. Immunocytochemistry shows that Myo5c antibodies label discreet puncta as well as tubules that span tens of μm through the cytoplasm in MCF-7 cells. The puncta are often closely associated with the plasma membrane near the leading edge of migrating MCF-7 cells. When transfected into MCF-7 cells, full-length GFP-Myo5c exhibits a punctate and tubular distribution similar to endogenous Myo5c. Wide-field epi-fluorescence imaging of live cells reveals that the tubules associated with GFP-Myo5c undergo long-range, highly dynamic movements at ~ 0.5 μm/sec. Nocodazole treatment (5μM) causes a dramatic loss of these cytopasmic tubules, demonstrating a dependence upon microtubules. Live-cell imaging using TIRF microscopy reveals that a sub-population of GFP-Myo5c puncta are closely associated with the ventral plasma membrane and undergo slower movements of ~0.03 μm/sec. The movements of these puncta are insensitive to nocodazole treatment, suggesting a dependence on f-actin. Our results suggest that Myo5c is associated with one or more organelles that are transported by microtubules and also interacts with f-actin at the cell cortex. (Supported by APS Porter Fellowship to DTJ and NIH/NIDCD grant DC03299 to REC)

### A Putative Role for Mammalian Class V Myosins in Transcription

A. J. Lindsay, M. W. McCaffrey; Biochemistry, University College Cork, Cork, Ireland

The two class V myosins in yeast, Myo2p and Myo4p, have been shown to play functional roles in a number of cellular processes, including. These include the regulation of proper mitochondrial, vacuolar, and ER inheritance during cell division, orientation of the mitotic spindle, mRNA transport and secretory vesicle transport. To date the three mammalian class V myosin isoforms, MyoVa, MyoVb, and MyoVc, have solely been implicated in membrane transport. We became interested in MyoVb when it was reported to interact with the small GTPase Rab11, and its interacting partner Rab11-FIP2. We generated a MyoVb-specific anti-peptide antibody, and were surprised to observe that in addition to labelling cytoplasmic vesicles it also displayed strong nuclear localisation, by immunofluorescence. We also observed a similar pattern for MyoVa using a commercial antibody. The nuclear localisation of both MyoV isoforms was confirmed biochemically. The observation that MyoVb was present in nucleoli where it colocalises with RNA polymerase I, and newly synthesised rRNA, led us to believe that it plays a role in transcription. Indeed, its nuclear localisation pattern was altered by transcription inhibitors. In contrast, MyoVa is excluded from the nucleolus and is unaffected by these inhibitors. As well as labelling vesicles, MyoVa also localised to P-bodies, cytoplasmic structures that are involved in mRNA degradation. We therefore believe that in addition to membrane transport these unconventional myosins may also be involved in regulating transcription and RNA turnover.

175

### Intracellular Dynamics of *Drosophila* Myosin-V

J. Toth, J. R. Sellers; Laboratory of Molecular Physiology, NHLBI, Bethesda, MD

We have studied the cellular role of myosin-V, an actin-based cytoplasmic motor, in *Drosophila*. The vertebrate and yeast myosin-Vs have been shown to associate with the endoplasmic reticulum, vacuoles and protein-RNA complexes through cargo specific adaptor molecules to function as organelle transporters. Vertebrate myosin-Va is a processive motor capable of carrying cargo for μm distances as a single molecule. Conversely, we have recently reported that the fly myosin-V is not processive therefore it has to function in ensembles. Such difference in the motor mechanism may reflect a different role in cytoplasmic transport. We created stable *Drosophila* S2 cell lines expressing full-length myosin-V or its C-terminal cargo binding domain fused to GFP. We performed confocal live cell imaging to investigate the intracellular dynamics of the overexpressed proteins. We used immunocytochemistry to determine the endogenous cellular distribution of myosin V in S2 cells. Our experiments show that in S2 cells, the endogenous myosin-V is mainly associated with the nuclear envelope and partially co-localizes with the endoplasmic reticulum but not the Golgi compartments. We observed partial co-localization with both filamentous actin and microtubules. In live cells, the full-length overexpressed protein exhibits diffuse cytoplasmic distribution dotted with vesicle-like moving structures. The cargo-binding tail fragments, on the other hand, concentrate mainly in bright dots that move unidirectionally in the cytoplasm at a speed of 0.32 ± 0.18 μm/s. These structures continue moving after the addition of actin or microtubule depolymerizing agents. Our results suggest that the fly myosin-V is associated with yet unidentified, potentially ER-derived vesicles that are transported on both the actin and microtubule networks. In this respect, *Drosophila* myosin-V functions similarly to other described vesicle transporter myosins.

176

**3-D Structure of the Inhibited State of Myosin V from Cryoelectron Tomography of 2-D Arrays**

J. Liu,[1] D. W. Taylor,[1] E. B. Krementsova,[2] K. M. Trybus,[2] K. A. Taylor[1]; [1]Institute of Molecular Biophysics, Florida State University, Tallahassee, FL, [2]Department of Molecular Physiology and Biophysics, University of Vermont, Burlington, VT

Myosin V (myoV) is a 2-headed molecular motor responsible for cargo transport along actin filaments in brain. In addition to its active state, myoV has a compact conformation formed in low [$Ca^{2+}$] that has low actin activated ATPase activity. We have formed 2-D arrays on lipid monolayers of recombinant full length myoV from mouse brain and used cryoelectron tomography of ice embedded arrays to obtain the first 3-D image of the inhibited conformation. The arrays have a hexagonal unit cell of dimension 65.3 nm but long range order is poor and the arrays have numerous defects. To obtain a resolution of 2.4 nm where an atomic model could be constructed, we used correspondence analysis to identify similar molecular structures within the arrays for subsequent averaging. The 3-D image has sufficient resolution to resolve the two lobes of the calmodulin light chains and to visualize the initial segment of the coiled-coil domain. The SH3 domain is clearly visible in the reconstruction facilitating unambiguous positioning of the myosin V motor domain crystal structure in the atomic model. The 3-D image reveals a compact conformation with the coiled-coil domain folded back between the two heads. Extra density that we assign to the cargo-binding domain is positioned on the motor domains in the vicinity of the ATP binding pocket. The actin binding interfaces are unobstructed by the cargo binding domain and the lever arm is oriented in a postpower stroke position typical of strong actin binding states. ATPase inhibition appears to be due to inhibition of nucleotide exchange. The structure suggests that motor recycling after cargo delivery occurs, not by diffusion, but through transport on actively treadmilling actin filaments. Supported by NIAMSD.

**Myosin Vc and Cytoplasmic Dynein are Enriched in Membrane Compartments in Lacrimal Acinar Epithelial Cells**

R. Marchelletta,[1] D. Jacobs,[2] R. Cheney,[2] J. A. Garner,[1] S. Hamm-Alvarez[1]; [1]University of Southern California, Los Angeles, CA, [2]University of North Carolina, Chapel Hill, NC

Acinar epithelial cells of the lacrimal gland are responsible for production and regulated release of tear proteins. A subset of membrane vesicles are enriched in myosin Vc (MyoVc). To help elucidate the function of MyoVc in this population, we have examined the vesicles for other constituents that may be co-localized. Primary rabbit lacrimal acini were isolated and cultured for 3 days. Confocal fluorescence microscopy and Nycodenz density gradient analysis were used to evaluate distributions of MyoVc, dynein, $p150^{Glued}$, the polymeric immunoglobulin A receptor (pIgR) and actin filaments in acini without or with carbachol (CCH, 100 μM) stimulation. For some experiments, acini were transduced on day 2 with replication-deficient adenovirus (Ad) encoding the dominant-negative MyoVc tail, fused to GFP (DN MyoVc) or GFP. The effect of DN MyoVc versus GFP on exocytosis was measured. Confocal fluorescence microscopy revealed MyoVc in association with large (1-2 μM) vesicles beneath the apical membrane in resting and CCH-stimulated acini. Dynein and $p150^{Glued}$ showed extensive colocalization with MyoVc, particularly in CCH-stimulated acini, while pIgR showed partial colocalization. These observations were validated by preliminary subcellular fractionations over Nycodenz density gradients. Functional analysis of the effects of DN MyoVc on secretion in acini transduced to ~90% efficiency revealed a modest (15%) but significant ($p \leq 0.05$, n=10) inhibition of CCH-stimulated β-hexosaminidase and bulk protein release; however, DN MyoVc significantly (($p < 0.05$, n=4) inhibited CCH-stimulated release of SC by ~50%. Confocal microscopy and biochemical studies support the enrichment of MyoVc and cytoplasmic dynein on the same membranes in lacrimal acini and suggest that MyoVc may facilitate CCH-stimulated SC release.

178

**Characterization of the *S cerevisiae* mRNA Localization Motor Myo4p**

B. D. Dunn, P. A. Takizawa; Cell Biology, Yale University, New Haven, CT

Cell polarity is established by targeting proteins to specific cellular locations. One mechanism to localize proteins is through the intracellular transport and localization of specific mRNAs. Subsequent translation leads to protein localization and cellular asymmetry. Both actin and microtubule based motors have been shown to transport mRNAs, but it is not known how these motors bind to specific mRNAs or how they efficiently move them. In the budding yeast *Saccharomyces cerevisiae*, the class V myosin Myo4p transports ASH1 mRNA to the bud tip. Two additional proteins, She3p and She2p, are required for Myo4p to associate with ASH1 mRNA. To understand how Myo4p transports ASH1 mRNA, we have developed a method to purify active Myo4p from yeast cell extracts. We find that She3p is tightly associated with Myo4p and co-purifies with the motor in an approximate ratio of 1:1. She3p acts as an adaptor linking Myo4p to She2p and the mRNA. We find that the amino-terminal half of She3p binds the predicted coiled-coil and tail domains of Myo4p, while the C-terminal half of She3p interacts with cargo. The *in vitro* rate of Myo4p movement as measured by actin gliding assays is approximately 1 μM/sec, which is consistent with *in vivo* mRNA transport. We have found that Myo4p is a monomeric motor, in contrast to all other known class V myosins. However, Myo4p still maintains a high affinity

for actin in the presence of ATP and has a high duty ratio in actin gliding assays, consistent with other class V myosins. These properties allow Myo4p to transport ASH1 mRNA transcripts to the bud tip rapidly and efficiently.

179

**Myosins Vc and Vb Sequentially Regulate Trafficking of Caveolar and Clathrin-Dependent Endocytotic Membranes**

Y. Chen,[1] L. B. Benseñor,[1] J. A. Mercer,[2] D. W. Provance,[2] J. R. Goldenring,[3] R. E. Cheney,[4] D. Jacobs,[4] G. S. Bloom[1]; [1]Department of Biology, University of Virginia, Charlottesville, VA, [2]McLaughlin Research Institute, Great Falls, MT, [3]Department of Surgery, Vanderbilt University, Nashville, TN, [4]Department of Cell and Molecular Physiology, University of North Carolina, Chapel Hill, NC

Trafficking of caveolar membranes, pigmented organelles and ER involves the cooperative action of actin filaments and microtubules, and myosin Va is an actin motor for pigmented organelle and ER transport. To determine if caveolar trafficking also requires a myosin V, caveolin-1 transport was studied in CHO cells expressing fluorescent dominant negative tail domains of myosin Va, Vb or Vc. All tail domains accumulated in multilamellar cytoplasmic structures, as judged by thin section EM. Caveolin-1 co-localized exclusively with myosin Vc tail, which also co-localized with transferrin receptor (TfR) and the early/sorting endosome marker, Rab5, and inhibited transferrin uptake. In contrast, myosin Vb tail co-localized with TfR, but with neither caveolin-1 nor Rab5. Markers for several other classes of membrane compartments, including late endosomes, lysosomes, autophagosomes and exosomes, failed to accumulate in the myosin Vc-positive compartment, Time lapse imaging of fluorescent versions of caveolin-1, endocytosed transferrin and Rab5 revealed caveolin-1 in both early/sorting and recycling endosomes. These data imply that caveolin-1, converges with transferrin and TfR in early/sorting and recycling endosomes, that progression from early/sorting to recycling endosomes requires myosin Vc, and that caveolin-1 segregates from transferrin and TfR in recycling endosomes before the latter two proteins return to the cell surface by a myosin Vb-dependent mechanism.

180

**The Effects of KE-PDZ Domain on Myosin 18A Distribution and ATPase Activity**

Y. Yang,[1] K. Sader,[2] Q. E. Xu,[1] J. Trinick,[2] J. R. Sellers[1]; [1]Laboratory of Molecular Physiology, National Heart, Lung and Blood Institute, Bethesda, MD, [2]School of Biomedical Sciences, Leeds University, Leeds, United Kingdom

There are at least two alternatively-spliced isoforms of myosin 18A. The α-isoform contains a tandem KE (lys-glu rich) and PDZ domain at its N-terminus (termed KE-PDZ), whereas the β-isoform lacks these motifs. Immuno-histochemical staining and western-blotting suggests that myosin 18A is predominantly expressed in adult mouse brain. Whole mount embryo sections staining reveals myo18A to be predominantly in epithelia cells of various tissues. The KE-PDZ domain is the main localization determinant of myo18A in epithelia cells. Transiently expressed KEPDZ domain distributes along actin filaments in filopodia and lamellipodia. The a-isoform is found in association with filaments, but the β-isoform has a more diffuse localization. Immunoprecipitation of myo18A from mouse brain extracts revealed that it is associated with LC17. We expressed the two truncated isoforms (HMMα and HMMβ) along with LC17in Sf9 cells. Both proteins were purified using the FLAG affinity epitope. EM results show that myo18A is a “two-headed” motor with very short neck consistent with its single IQ motif. HMMα binds to actin in an ATP-independent manner, probably due to the KE-PDZ domain. HMMβ binds to actin in an ATP-dependent manner. Interestingly, both HMMs show weak rigor binding to actin in the absence of ATP. ATPase assays reveal that both isoforms have actin activated-Mg ATPase activity, however the Vmax of α-isoform (0.5 $s^{-1}$) is higher than that of β-isoform (0.07 $s^{-1}$). The $K_{ATPase}$ of α-isoform is 10.1 μM which is 2.4 times lower than that of β-isoform. All the data suggest that KE-PDZ domain involves not only localization of myo18A in epithelia cell, but the regulation of ATPase activity compared to other myosins.

**Targeted Disruption of *Myo18B* Results in Myocardial Defects and Embryonic Lethality**

R. Ajima,[1] H. Akazawa,[2] M. Kodama,[3] F. Takeshita,[3] A. Otsuka,[1] M. Tani,[1] T. Kohno,[1] I. Komuro,[2] T. Ochiya,[3] J. Yokota[1]; [1]Biology Division, National Cancer Center Institute, Tokyo, Japan, [2]Department of Cardiovascular Science and Medicine, Chiba University Graduate School of Medicine, Chiba, Japan, [3]Section for Studies on Metastasis, National Cancer Center Institute, Tokyo, Japan

*MYO18B* is a novel unconventional *MYOSIN* gene that was identified from a homozygously deleted region on chromosome 22q in a human lung cancer cell line. Frequent inactivation of this gene in human cancer cells by genetic and/or epigenetic alterations, and suppression of anchorage-independent growth by restoration of its expression suggest that the *MYO18B* gene functions as a tumor suppressor in human carcinogenesis. However, functions of MYO18B in normal cells are still unclear. To investigate the functions of Myo18B *in vivo,* we had generated *Myo18B* gene deficient mice by knocking-in the *nls-LacZ* gene. Deficiency of *Myo18B* in mice resulted in lethal cardiac defects between embryonic day 10.5 (E10.5) and E11.5. LacZ staining of *Myo18B* gene targeted mice tissues or embryos revealed that Myo18B was expressed predominantly in muscles, both in embryonic and adult tissues. We performed immunohistochemical analysis using antibodies against Myo18B to examine the localization of Myo18B in myocytes and muscles. Myo18B localized on F-actin in myocytes and on Z-lines in skeletal and cardiac muscles. Myo18B did not co-localize with type II myosin in skeletal muscles. The localization suggests that Myo18B plays a distinct role from conventional myosins. Furthermore, we performed a reporter assay of *Myo18B* gene promoter to investigate the regulation of *Myo18B* gene expression in myocytes. As expected, the Myo18B promoter was activated by differentiation of C2C12 myocytes. The *Myo18B* gene promoter region contains a myocyte-specific enhancer factor-2 (MEF2) binding site. Mutation of MEF2 binding site decreased basal expression and activation of Myo18B promoter. Thus, it was suggested that MEF2 might regulate Myo18B expression in myocytes. We conclude that Myo18B is a protein that is expressed mainly in muscles and its expression is crucial for cardiac development.

**Biochemical and Motile Properties of Myo1b Splice Isoforms**

T. Lin, N. Tang, E. M. Ostap; Physiology, University of Pennsylvania School of Medicine, Philadelphia, PA

Myo1b is a widely expressed myosin-I isoform that concentrates on endosomal and ruffling membranes and is thought to play roles in membrane trafficking and dynamics. Myo1b is alternatively spliced within the regulatory (lever-arm) domain, yielding isoforms with six (myo1b$^{a}$), five (myo1b$^{b}$) or four (myo1b$^{c}$) non-identical IQ motifs. The first three IQs motifs (IQ1-3) are the same for each splice isoform, and splicing occurs

within IQ4-6. Myo1b[a] contains IQ4, IQ5, and IQ6, myo1b[b] contains IQ6 and is spliced within IQ4 and IQ5 resulting in a IQ4/5 hybrid, and myo1b[c] is spliced within IQ4 and IQ6, resulting in the creation of a IQ4/6 hybrid and the loss of IQ5. The calmodulin binding properties of the myo1b IQ motifs have not been investigated, and the mechanical and biological consequences of splicing are not known. Therefore, we expressed the alternatively spliced myo1b isoforms, and we expressed a construct containing a single IQ domain. The constructs were truncated after the final IQ domain and contained a sequence at their COOH-termini that is a substrate for biotin ligase. Site-specific biotinylation allows us to specifically attach the myosin to motility surfaces via a biotin-streptavidin linkage. We measured the ATPase and motile properties of the recombinant myo1b splice isoforms, and correlated these properties with calmodulin binding. We confirmed that calcium-dependent changes in the ATPase activity are due to calcium binding to the calmodulin closest to the motor. We found that calmodulin binds tightly to IQs 1-3 (Kd < 0.2 μM) and very weakly to the alternatively spliced IQ motifs (Kd > 5 μM). Additionally, we found that the motility rate is not linearly related to the number of IQ motifs, suggesting that the calmodulin-saturated regulatory domains of the splice isoforms do not act as rigid lever arms.

183

### Myo1c Binds Tightly and Specifically to $PIP_2$ and $IP_3$

D. E. Hokanson, E. M. Ostap; Physiology, University of Pennsylvania Med School, Philadelphia, PA

Myosin-I is a single-headed, low-molecular-weight member of the myosin superfamily that is thought to associate with acidic phospholipids via its tail domain. Although membrane association is essential for proper myosin-I localization and function, little is known about the physiological relevance of the direct association of myosin-I with phospholipids or about phospholipid head-group binding specificity. To better understand the mechanism of myosin-I-membrane association, we measured effective dissociation constants for the binding of a recombinant myosin-I (myo1c) IQtail construct (which includes three IQ motifs and bound calmodulins) to sucrose-loaded, large unilamellar vesicles (LUVs) composed of phosphatidylcholine (PC) and various concentrations of phosphatidylserine (PS) or phosphoinositol 4,5-bisphosphate ($PIP_2$). We found that the myo1c-IQtail binds tightly to LUVs containing ≥ 60% PS, but very weakly to LUVs containing physiological PS concentrations. Remarkably, the myo1c-IQtail binds tightly to LUVs containing just 2% $PIP_2$, which have a charge equivalent to 6% PS. Additionally, we found that myo1c-IQtail binds to soluble inositol-1,4,5-trisphosphate ($IP_3$) with approximately the same affinity as to $PIP_2$ in LUVs, suggesting that myo1c binds specifically to the head-group of $PIP_2$. An expression construct consisting of the myo1c motor and IQ domains does not bind LUVs containing 2% $PIP_2$, confirming that the $PIP_2$ binding site is in the tail. Finally, we show that a GFP-myosin-I-tail chimera expressed in epithelial cells is transiently localized to regions known to be enriched in $PIP_2$, and that this localization is disrupted by elevated concentrations of intracellular calcium. Our results suggest that myo1c does not bind to physiological concentrations of PS, but rather binds tightly to $PIP_2$.

### NMR Structural Study of the *Acanthamoeba* Myosin IC Tail

K. Hwang,[1] F. Mahmoodian,[2] J. M. Gruschus,[1] J. A. Ferretti,[1] E. D. Korn[2]; [1]Laboratory of Biophysical Chemistry, NHLBI, NIH, Bethesda, MD, [2]Laboratory of Cell Biology, NHLBI, NIH, Bethesda, MD

The tail of *Acanthamoeba* myosin IC (AMIC) comprises an N-terminal 220-residue basic region (BR) followed by a 56-residue Gly/Pro/Ala-rich region (GPA1), a 55-residue SH3 domain and a C-terminal 133-residue GPA2 region. Previous cryo-electron microscopy [Ishikawa et al. (2004) PNAS 101, 12189-12194] indicated that the tail was folded back on itself between BR and GPA1 and between GPA1 and GPA2, implying intramolecular interactions among the tail regions. We have initiated NMR studies to determine the structure of the tail and identify specific interactions within it. We expressed three proteins labeled with $^{15}N$ and $^{15}N/^{13}C$: full-length tail, the BR region and the GPA1-SH3-GPA2 segment. $^{15}N/^{13}C$-labeled BR was also expressed in medium containing 65% $D_2O$ to provide higher quality spectra. NMR conditions were optimized for solubility and stability (25 $^{o}$C, 40 mM KCl, 20 mM phosphate, pH 6.5, and 0.5 mM TCEP as a reducing agent). For protein backbone resonance assignment, we used 2D HSQC, $^{15}N$ NOESY, $^{13}C$ NOESY, HNCACB, CBCACONH, and HNCOCAB pulse experiments. The N-terminal basic region showed some β-sheet secondary structure; sequence alignment showed no similar structure in the data base. Superposition of the NMR spectra of the full-length tail with the spectra of the individually expressed BR and GPA1-SH3-GPA2 segments showed some differences, implying that there is some interaction between the N-terminal and C-terminal regions of the full-length tail. We will identify and characterize the flexible, folded and partially folded regions of the full-length tail using the spectra from all three expressed proteins. Furthermore, we will use a homology modeling approach to predict some possible conformationally dependent interactions between the N- and C-terminal halves. We expect these studies will provide additional information on any possible interactions between different regions of the tail of *Acanthamoeba* myosin IC.

185

### Identification and Characterization of Novel Light Chains Associated with the *Dictyostelium discoideum* Class-I Myosins

S. W. Crawley, Y. Yang, L. M. Dryden, A. Bigg, S. P. Smith, G. P. Cote; Biochemistry, Queen's University, Kingston, ON, Canada

The *Dictyostelium discoideum* class I myosins are single-headed, non-filament forming motor proteins composed of a heavy chain and one or more light chains. We have identified and characterized two novel light chains associated with MyoB and MyoD. The light chain associated with MyoD, termed MlcD, is 16 kDa in size and has a typical, calmodulin-like domain structure with four putative EF-hand motifs. In contrast, MyoB contains a small 8-kDa light chain, termed MlcB, that contains only two EF-hand motifs. MlcB binds $Ca^{2+}$ with a $K_d$ value of 0.2 $\mu$M, indicating that it may act as a physiological sensor of *in vivo* $Ca^{2+}$ levels. Mutational analysis shows that the first EF-hand of MlcB is solely responsible for binding $Ca^{2+}$. The solution structure of MlcB in the $Ca^{2+}$-free state is now being solved. MlcB binds to a peptide corresponding to the MyoB IQ motif in the absence and presence of $Ca^{2+}$ with $K_d$ values of 1.2 and 0.5 $\mu$M, respectively. Interestingly, calmodulin binds to the MyoB IQ motif peptide with a similar affinity; however, the binding is strictly $Ca^{2+}$ dependent. Competition assays indicate that MlcB and calmodulin binding to the MyoB IQ motif peptide are mutually exclusive events. The possibility that MyoB can switch light chains in a $Ca^{2+}$-dependent manner is being investigated. Searches of dictyBase (http://www.dictybase.org) show that *Dictyostelium* contain a second small two-EF-hand protein (DDB0219456) that is 37% identical to MlcB. This protein, tentatively termed MlcX, does not bind to the MyoB IQ motif peptide. A FLAG-tagged MlcX has been expressed in *Dictyostelium* and the identification of interacting proteins is currently underway.

**Unconventional Myosin 1e Promotes Actin Assembly during Compensatory Endocytosis in *Xenopus* Eggs**

H. E. Yu,[1] W. Bement[2]; [1]Program in Cellular and Molecular Biology, University of Wisconsin -- Madison, Madison, WI, [2]Dept of Zoology, University of Wisconsin -- Madison, Madison, WI

In *Xenopus* eggs, exocytosing cortical granules (CGs) are surrounded by actin "coats", which drive compensatory endocytosis (Sokac *et al.*, Nat Cell Biol. 5: 727-32, 2003). In combination with inositol triphosphate ($IP_3$) uncaging to elevate $Ca^{2+}$ and trigger CG exocytosis, we used time-lapse microscopy to study the role of "unconventional" myosin 1e in the actin coat assembly. Myosins, which bind to filamentous actin, have long been identified as important molecular motors that transport cargos and produce contraction power. Besides the highly conserved motor domain that is present in all myosins, myosin 1e has a long tail that is comprised of 3 myosin tail homology (MyTH) domains. Inhibition of myosin 1e abolished actin coat assembly, suggesting that this myosin actually promotes actin assembly. In addition, our results showed that the MyTH1 and MyTH2 domains of the myosin 1e tail are sufficient for proper myosin 1e recruitment to the exocytosing CGs. More importantly, the MyTH2 domain of myosin 1e preferentially associated with more dynamic actin, giving rise to the possibility that this myosin can target specifically to rapidly assembling actin. Thus, myosin 1e may not only promote actin coat assembly, but may also function to compress the actin coat by tethering the newly assembled actin.

187

**Myo3A Binds Specific Phospholipids via IQ Motif-rich Regions in its Neck and Tail**

A. C. Dosé, A. C. Corsa, B. Burnside; MCB, UC Berkeley, Berkeley, CA

Myo3A is expressed in photoreceptors and ear hair cells. In photoreceptors Myo3A localizes specifically to actin filament bundles of calycal processes. To investigate whether Myo3A binds membrane lipids, we used a protein-lipid overlay assay (PIP strips™, Echelon Inc.). Various Myo3A neck and tail fusion protein constructs were tested. The neck (IQ motifs 1-4) and tail (IQ 5-9) bound to phosphatidylinositol-monophosphates [PI(3)P, PI(4)P and PI(5)P] and phosphatidylinositol-diphosphates [$PI(3,4)P_2$, $PI(3,5)P_2$ and $PI(4,5)P_2$], as well as $PI(3,4,5)P_3$ and phosphatidic acid (PA). To quantify relative affinities for lipids, fusion proteins were tested on PIP arrays, which consist of serial dilutions of phosphoinositol phosphates. Affinities for monophosphates were strongest followed by affinities for di- and triphosphates. A similar pattern was observed for a 23 amino acid fusion protein between IQ motifs 4 and 5. IQ motif 4 alone did not bind phospholipids, nor did the tail domain beyond the last IQ motif. Calmodulin binds to IQ motifs and can compete for lipid binding (as seen for myosin IC). To test whether Myo3A IQ motifs could be affected by the presence of CaM, the neck (1-4) and tail (5-9) IQ domain fusion proteins were overlayed on PIP strips in the presence of 25 υM CaM either with 25 υM $Ca^{2+}$ or 100 υM EDTA. The neck did not bind to $PI(3,4,5)P_3$ or PA in the presence of $Ca^{2+}$ and CaM while the tail binding pattern is unaffected. These data indicate Myo3A binds lipids, mediated at least in part by a region between IQ motifs 4 and 5, and calmodulin. These findings suggest Myo3A may play a role in transporting or localizing lipids within the inner segment and calycal processes of photoreceptors.<br

**Myosin VI: An Actin Stabilizer, Not a Cargo Transporter**

T. Noguchi,[1] M. Lenartowska,[2] K. G. Miller[1]; [1]Biology, Washington University in St. Louis, St. Louis, MO, [2]Institute of General and Molecular Biology, Nicolaus Copernicus University, Torun, Poland

To understand the in vivo function of myosin VI, we analyzed the *Drosophila* myosin VI mutant during the individualization stage of spermatogenesis. Actin based machinery consisting of 64 actin cones divides the 64 syncytial spermatids into individual sperm as cones move though whole spermatids. In vitro culture of myosin VI mutant spermatogenic cysts demonstrates that cone movement initiates normally but stops prematurely. The actin cones cannot maintain the normal accumulation of actin during movement. Over expression of myosin VI leads to increase of extra F-actin in the actin cone. S1 labeling demonstrates that actin cone has front half consists of a densely packed meshwork of F-actin and rear half with long actin bundles. In addition, unlike Listeria actin comet tail or lamellipodial actin network, the vast majority of F-actin have their pointed ends facing forward of the cone. In myosin VI mutants, the F-actin density is much less, and the meshwork in the front half of the cone is much smaller. Myosin VI localizes to the front edge of the cone where a number of pointed end of F-actin exposed to cytoplasm, and it is structurally protecting the network. ATP extraction of GFP-myosin VI from permeabilized cysts demonstrated that the myosin VI motor domain is important for localization. FRAP of GFP-myosin VI demonstrated that myosin VI remained bound to the actin cone for several minutes suggesting its role is structurally tethering or cross linking. These data suggest that myosin VI structurally stabilizing actin cone rather than transporting membrane vesicle.

189

**The PDZ Adaptor Protein Synectin Targets Myosin VI to Endocytic Vesicles**

A. Horowitz,[1] S. Naccache,[2] T. Hasson[2]; [1]Angiogenesis Research Center, Dartmouth Medical School, Lebanon, NH, [2]Division of Biological Sciences, University of California at San Diego, La Jolla, CA

We have recently shown that translocation of uncoated endocytic vesicles (UCV) through the cortical actin mesh is facilitated by myosin VI (myo6). This unconventional myosin is capable of supporting inward movement of UCV being the only known retrograde-moving actin-based molecular motor. The PDZ domain-containing adaptor protein synectin collocates with myo6 on UCV and may conceivably mediate myo6 recruitment to this organelle. We tested this hypothesis first by examining synectin targeting to UCV in myo6-null cells. Synectin was still localized to UCV, thus indicating that its targeting preceded and was not dependent on myo6. We next investigated the docking mechanism of synectin and myo6 to UCV by expressing a series of synectin mutants where either the N-terminus domain, the central PDZ domain, or the C-terminus domain was partially or completely truncated. A mutant consisting of the N-terminus and PDZ domains was the minimal fragment sufficient for synectin targeting to UCV. The myosin-VI binding motif was narrowed down to the carboxy terminus of synectin. Strikingly, a loss-of-function point mutation in the PDZ domain of synectin not only blocked UCV targeting, but also abolished myo6 binding. Saturation binding assays revealed that ligand binding to the PDZ domain of synectin increased the Vmax of the synectin-myo6 interaction, indicating that ligand binding has an allosteric effect - it stabilizes a synectin conformation where the myo6 binding site is accessible. The emerging docking mechanism

of myo6 to UCV suggests that the PDZ domain of synectin plays an active role in recruiting myo6 to UCV. The docking consists of two steps: (1) clathrin uncoating exposes the PDZ-binding motifs present in the carboxy-termini of transmembrane receptors, thus facilitating synectin binding; (2) once the PDZ domain is engaged, the myo6 binding motif in the carboxy-terminus becomes functional.

190

**TalinA is Stabilized by Binding to Myosin VII**

S. A. Galdeen, S. Stephens, M. A. Titus; Genetics, Cell Biology, and Development, University of Minnesota, Minneapolis, MN

Myosin VII (M7) and talin each function in both *Dictyostelium* and higher eukaryotes as a component of an adhesion complex that links membrane receptors to the actin cytoskeleton. Recent studies have identified talinA as a direct interactor with *Dictyostelium* M7 (DdM7) (Tuxworth, et. al. 2005) and suggested that this association is required for proper assembly of a membrane-receptor complex. In a separate study, Gebbie et. al. (2004) reported that talinA is absent in DdM7 null cells. The potential link between DdM7 and talinA levels has been examined in more detail to better understand the functional relationship between these two adhesion proteins. Western blotting reveals that talinA protein levels are linked to the expression of DdM7, with DdM7 null cells expressing 17% of the wild-type level of talinA. Real-time QPCR of cDNA from cells with altered DdM7 expression indicates that there is no change in talinA RNA levels, suggesting that DdM7 provides steric protection against talinA degradation. Examination of protein degradation kinetics confirms that talinA protein in cells lacking DdM7 is lost twice as fast as in wild-type cells. Interestingly, talinA localization is unaffected by the loss of DdM7. Overexpression of the DdM7 tail domain alone in DdM7 null cells restores talinA levels; however, the phagocytic defect that DdM7 null cells exhibit is not rescued, confirming that DdM7 has a function in adhesion that is independent of its binding to talinA. These results establish that DdM7 plays a role in function of an adhesion complex and stabilization of talinA *in vivo*.

191

**ATPase Cycle Mechanism of *Drosophila* Myosin VIIA**

S. Watanabe, R. Ikebe, M. Ikebe; Physiology, University of Massachusetts Medical School, Worcester, MA

Mutations of myosin VIIA cause deafness in species from human and mice to zebrafish and *Drosophila*. To understand the motor properties of myosin VIIA, we analyzed the kinetic mechanism of *Drosophila* myosin VIIA ATPase cycle using a truncated construct with entire neck domain (DM7AIQ5). $V_{max}$ and $K_{ATPase}$ of the steady state actin-activated ATPase activity of DM7AIQ5 were 1.2 $s^{-1}$ and 4.2 μM, respectively. The ATP hydrolysis rate (13.7 $s^{-1}$) was slow, but much faster than the $V_{max}$. The phosphate release rate from actoDM7AIQ5 (>50 $s^{-1}$) was also much faster than the $V_{max}$. Thus, ATP hydrolysis and phosphate release are not the rate-limiting steps. The rate of ADP release from actoDM7AIQ5 was 1.8 $s^{-1}$, which was close to the $V_{max}$. Pi-burst size was low (0.35 mol/mol) indicating that the equilibrium in ATP hydrolysis step is significantly shifted toward the pre-hydrolysis intermediate. Overall, the ATPase cycle rate of myosin VIIA is limited by slow ADP release. From the obtained data, it was concluded that myosin VIIA is a high duty ratio motor.

192

**Myosin-X (Myo10) is a Filopodial Motor Protein that Promotes Filopodia**

A. Bhaskar, B. W. Robertson, R. E. Cheney; Cell and Molecular Physiology, University of North Carolina at Chapel Hill, Chapel Hill, NC

Little is known about the molecular machinery regulating filopodia formation. Since Myo10 is a motor protein that localizes to filopodial tips, we sought to determine if Myo10 is a component of this machinery and have used scanning EM to ask if Myo10 promotes the formation of dorsal filopodia. We find that over-expressing Myo10 in cells such as COS-7 (which normally lack filopodia) dramatically increases dorsal filopodia. The MyTH4, but not the FERM domain of Myo10 is necessary for this filopodia promoting activity. Since VASP can also induce filopodia, we next tested if Myo10 can induce filopodia independent of VASP. Surprisingly, over-expression of Myo10 in Ena/VASP null MVD7 cells dramatically increases dorsal filopodia, demonstrating that Myo10 can induce filopodia in the absence of VASP. To test if endogenous Myo10 is necessary for filopodia formation, HeLa cells (which normally have numerous filopodia) were treated with a siRNA against Myo10. This treatment resulted in greater than 90% knockdown and a striking reduction in dorsal filopodia. To confirm that Myo10 is central to filopodia formation, we generated a coiled-coil construct to use as a potential dominant negative. Expression of this construct in HeLa cells also potently suppressed dorsal filopodia. Since Cdc42 is known to be a master regulator of filopodia formation, we next asked if Myo10 acts upstream or downstream of Cdc42. Myo10 siRNA treated HeLa cells transfected with constitutively active Cdc42 (which can induce filopodia in COS-7 cells) had remarkably reduced filopodia indicating that Myo10 is downstream of Cdc42. Taken together, these results demonstrate that Myo10 is a potent stimulator of filopodia, that the MyTH4 domain of Myo10 is necessary for filopodia formation, and that Myo10 functions downstream of Cdc42. Supported by an AHA fellowship to AB and NIH/NIDCD grant DC03299 to REC.

193

**Myosin X is a High Duty Ratio Motor**

K. Homma, M. Ikebe; Physiology, UMass Medical School, Worcester, MA

Myosin X is expressed in a variety of cell types and plays a role in cargo movement and filopodia extension, but its mechanoenzymatic characteristics are not fully understood. Here we analyzed the kinetic mechanism of the ATP hydrolysis cycle of acto-myosin X using a single-headed construct (M10IQ1). Myosin X was unique for the weak "strong actin binding state" (AMD) with $K_d$ of 1.6 μM due to the large dissociation rate constant (2.1 $s^{-1}$). $V_{max}$ and $K_{ATPase}$ of the actin-activated ATPase activity of M10IQ1 were 13.5 $s^{-1}$ and 17.4 μM, respectively. The ATP hydrolysis rate (>100 $s^{-1}$) and the phosphate release rate from acto-myosin X (>100 $s^{-1}$) were much faster than the entire ATPase cycle rate and, thus, not rate limiting. The ADP off rate from acto-myosin X was 23 $s^{-1}$, which was two times larger than the $V_{max}$. Pi-burst size was low (0.46 mol/mol) indicating that the equilibrium is significantly shifted toward the pre-hydrolysis intermediate. The steady-state ATPase rate can be explained by combination of the unfavorable equilibrium constant of the hydrolysis step and the relatively slow ADP off rate. The duty ratio calculated from our kinetic model, 0.6, was consistent with the duty ratio, 0.7, obtained from comparison of $K_{m\ ATPase}$ and $K_{m\ motility}$. Our results suggest that myosin X is a high duty ratio motor.

194

**Myosin Genes in Tetrahymena thermophila**

S. A. Williams, R. H. Gavin; Biology, Brooklyn College - CUNY, Brooklyn, NY

Analysis of the Tetrahymena thermophila macronuclear genome sequence revealed 13 myosin genes. This report presents an initial comparison of motor, neck, and tail domains of the 13 Tetrahymena myosins. The myosins in Tetrahymena did not align with any of the previously named myosin classes. Twelve of the myosins form a new class designated as XX. The other myosin is divergent from the twelve. Eleven of the motor domains in Tetrahymena myosins are slightly larger than the muscle myosin motor. Six of the Tetrahymena myosins contain putative IQ sequences. One of these myosins, Myo1, contains a putative IQ sequence within the FERM motif. The average length of the putative IQ sequence in the six Tetrahymena myosins is 22 aa. Seven of the Tetrahymena myosins do not contain an apparent IQ motif. Eleven of the myosins in Tetrahymena contain one or more coiled-coil sequences. The average number of heptads is 6, and only one of the Tetrahymena myosins, Myo13, appears to contain a sufficient number of heptads to support dimer formation. Seven of the Tetrahymena myosins do not contain known conserved tail domain motifs that could interact with cargo. Six of the myosins contain the myosin tail homology (MyTH4) and/or ezrin, radixin, moesin homology (FERM) motifs. One myosin contains only MyTH4 in the tail domain, and one myosin contains only FERM. Four of the Tetrahymena myosins contain both MyTH4 and FERM. Surprisingly, none of the myosins in Tetrahymena aligned with either class I, class II, or class V myosins. Apparent absence of a class II myosin is an indication that contractile ring assembly and function during cytokinesis in Tetrahymena either utilizes an unconventional myosin or does not require a myosin motor. [Supported by National Science Foundation grant 0130624]

195

**Processivity of Plant (*Chara*) Myosin**

K. Ito, E. Okutsu, Y. Wanikawa, Y. Hachikubo, K. Yamamoto; Biology, Chiba University, Chiba, Japan

Very fast cytoplasmic streaming (~70 μm/s) can be observed in fresh water alga *Chara*. This streaming is generated by the sliding movement of *Chara* myosin along the fixed cortical actin bundles with its tail attached to endoplasmic reticulum net work. Since many kinds of myosin carrying cargo are processive motor, we examined the processivity of *Chara* myosin by both landing assay and kinetic analysis. Landing rate of actin filaments on the glass surface covered with *Chara* myosin was similar to that of skeletal muscle myosin. The actin activated ATPase activity of this myosin was very high (Vmax = 388 Pi/head/s at 25 °C). We calculated duty ratio by measuring the time constant of strongly bound state. Strongly bound state consists two states, ADP bound state and nucleotide free state. The time constants of the ADP bound state and nucleotide free state were 0.4 ms and 0.1 ms, respectively at 25 °C. Since the total cycle time of ATPase activity was 2.6 ms, duty ratio was calculated to be 0.19. These results suggested that *Chara* myosin is not a processive motor. In the cytoplasm of *Chara*, myosin molecules are attached to the network of endoplasmic reticulum membrane and cannot diffuse away from actin bundles easily; the situation relative to actin is similar to that in skeletal muscle. Therefore, *Chara* myosin does not have to be a processive motor to generate cytoplasmic streaming.

196

**Interaction of *Chara* Myosin with Phospholipid Vesicles**

S. Nunokawa,[1] K. Shimada,[2] K. Ito,[1] K. Yamamoto[1]; [1]Biology, Chiba University, Chiba, Japan, [2]Kazusa DNA Institute, Chiba, Japan

Class XI unconventional myosin generates cytoplasmic streaming by moving along the fixed cortical actin bundles with its tail attached to endoplasmic reticulum membrane in characean alga. To explore the nature of the interaction with membrane, we expressed the globular tail domain of *Chara* myosin in insect cells, purified it, and studied its interaction with artificial phospholipid vesicles. It was found that the globular tail domain co-precipitated with vesicles made from acidic phospholipid such as phosphatidyl serine (PS) but not with ones made from neutral phospholipid such as phosphatidyl choline (PC). This interaction was weakened by the increase in the ionic strength suggesting that the interaction is electrostatic by nature. We then studied the affinity between the globular tail of *Chara* myosin and membrane vesicles made from phospholipid mixture to make the situation more natural. When the mixture contained 20 % PS and 80 % PC, the dissociation constant was 130 nM. We also measured the concentration of *Chara* myosin in the cell using quantitative immunoblot. We also calculated the amount of phospholipid in the endoplasmic reticulum of characean cells under certain assumptions. From these values, we estimated that more than 80 % of *Chara* myosin is attached to membrane just through electrostatic interaction.

197

**The Novel Myosin Myo19 is a Putative Motor for Mitochondrial Movement**

O. A. Quintero,[1,2] M. B. Kortan,[2] R. E. Cheney[1]; [1]Cell and Molecular Physiology, UNC-Chapel Hill, Chapel Hill, NC, [2]Biology, Franklin and Marshall College, Lancaster, PA

Mitochondria play key roles in ATP production, apoptosis, and calcium signaling. Although mitochondria are implicated in diabetes, aging, and neurodegenerative disorders, the mechanisms of mitochondrial movement and cellular localization remain unclear. Previous studies have shown that mitochondria move on both actin and microtubules in neuronal cells (RL Morris and PJ Hollenbeck, JCB, 1995). Here we report that a novel human myosin, tentatively named Myo19, localizes to mitochondria. Myo19 transcripts of approximately 4.3kb were identified in multiple tissues. Human Myo19 is a 970 amino acid protein consisting of a myosin motor domain, three IQ motifs, and a short tail region with no obvious homologies. The c-terminal 186 amino acids of Myo19 are necessary and sufficient for the localization of Myo19 to mitochondria, as GFP constructs lacking the tail region of Myo19 fail to localize to mitochondria, and GFP constructs consisting of just the c-terminal tail region localize to mitochondria. Overexpression of GFP-Myo19 tail in A549 cells resulted in a 50% decrease in average velocity of moving mitochondria compared to mitochondria in untransfected cells. In cells overexpressing full length GFP-Myo19, mitochondrial were observed with an asymmetric, “tadpole” shape with the wider end leading the movements. Mitochondria were observed to move for many micrometers at an average velocity of 81.5±4.2 nm/s. Treatment of A549 cells overexpressing full length GFP-Myo19 with 15μM nocodazole failed to abolish mitochondrial movements, whereas treatment with 500 nM latrunculin B resulted in the cessation of mitochondrial movements. Taken together, these results suggest that Myo19 is an unconventional myosin involved in the motility and localization of mitochondria. Supported by a SPIRE postdoctoral training grant NIH/GM00678 to OAQ, and NIH/NIDCD DC03299 to REC.

### Two-dimensional Averaged Images of the Dynactin Complex Revealed by Single Particle Analysis

H. Imai,[1,2] A. Narita,[1,2] T. A. Schroer,[3] Y. Maeda[1,2,4]; [1]Explatory Research for Advanced Technology (ERATO), Japan Science and Technology Agency (JST), Hyogo, Japan, [2]Structural Biochemistry Laboratory, RIKEN Harima Institute at SPring-8, Hyogo, Japan, [3]Department of Biology, Johns Hopkins University, Baltimore, MD, [4]Department of Biological Science, Nagoya University, Nagoya, Japan

The dynactin complex interacts with dynein and numerous other proteins to provide for a wide range of subcellular transport functions. A detailed understanding of dynactin structure and subunit organization is likely to yield new insights regarding dynactin function. In the present study, we used single particle analysis to obtain two-dimensional averaged image of dynactin complex isolated from chick embryo brains visualized by negative stain EM. The averaged image was highly reminiscent of previously published deep etch electron micrographs. The overall length distribution was tightly clustered as ≈40 nm. Each image showed a prominent shoulder complex and the pointed-end complex and mass associated with the barbed-end of the Arp1 mini-filaments were prominent in contrast to the simple Arp1 polymer that was observed by single particle analysis of brain dynactin (Hodgkinson et al., 2005). The differences should not be accounted for by different sources, but by disrupted preparations which were used for their analysis.

### A New Quick Freeze-Deep Etch-Tomographic Analysis of the Flagellar Outer Dynein Arm Complex

P. Lupetti,[1] S. Lanzavecchia,[2] D. Mercati,[1] F. Cantele,[2] R. Dallai,[1] C. Mencarelli[1]; [1]Dept. of Evolutionary Biology, University of Siena, Siena, Italy, [2]Dept. of Structural Chemistry, University of Milano, Milano, Italy

We present here a 3D reconstruction of in situ axonemal outer dynein arms obtained by electron tomography applied to a series of tilted images collected from metal replicas of rapidly frozen, cryofractured, and metal replicated sperm axonemes of the gall-midge fly *Monarthropalpus flavus*. This peculiar axonemal model consists of several microtubular laminae that proved to be sufficiently planar to allow the visualization of many doublet microtutules with their dynein complexes within the same fracture face. This structural feature allowed us to recover a significant number of equivalent objects and to improve the signal to noise ratio of the dynein reconstruction by applying advanced averaging protocols. The 3D model we obtained showed the following interesting structural features: First, each dynein arm has two head domains that are almost parallel and are obliquely oriented with respect to the longitudinal axis of microtubules. The two heads are therefore positioned at different distances from the surface of the A-tubule. Second, each head domain consists of a series of globular subdomains that are positioned on the same plane. Third, a stalk domain originates as a conical region from the proximal head and ends with a small globular domain that contacts the B-tubule. Fourth, the stem region comprises several globular subdomains and presents two distinct points of anchorage to the surface of the A-tubule. Finally, and most importantly, contrary to what has been observed in isolated dynein molecules adsorbed to flat surfaces, the stalk and the stem domains are not in the same plane as the head. This implies that, the force generated during the power stroke, would only act along the longitudinal axis of microtubules if a substantial rearrangement occurred in the stalk-head orientation.

### A Role for the Mitotic Checkpoint Protein ZW10 as a Vesicular Membrane Anchor for Cytoplasmic Dynein

D. Varma, R. B. Vallee; Cell Biology and Pathobiology, Columbia University, New York, NY

Cytoplasmic dynein is involved in a multitude of interphase cellular functions, including organization of the Golgi apparatus, endosome and lysosome transport, and maintenance of the centrosome-centered array of interphase microtubules. ZW10 is a mitotic checkpoint protein that is the well-established anchor for cytoplasmic dynein at mitotic kinetochores [Starr *et. al., JCB, 142 (3), 1998*]. However, it is expressed throughout the cell cycle, suggesting a potential interphase role as well. We have previously reported that ZW10 localizes to the Golgi apparatus in interphase cells and cosediments with Golgi membranes [Dujardin *et. al., Mol. Biol. Cell 12:163a*]. Furthermore we found that perturbation of ZW10 function by dominant negative overexpression and antibody injection caused dispersal of Golgi stacks, suggesting a role for ZW10 in interphase dynein function. Recently, however, ZW10 was reported to associate with a complex potentially involved in ER/Golgi trafficking, consisting of the t-SNARE syntaxin-18 and associated proteins, and the rad50-interacting protein RINT-1 [Hirose *et. al., EMBO J, 23 (6) 2004*]. The current study was undertaken to test directly for a role for ZW10 in interphase dynein function. Golgi, endosome, and lysosome markers were all disrupted by ZW10 RNAi. Microtubule organization was also disrupted in 80% of the cells, an effect associated with a substantial increase in centrosome number. Live-cell imaging in the subset of cells with normal radially arrayed microtubules revealed an ~70% decrease in the frequency of minus-end directed Golgi vesicular movements. Similar results were obtained with endosomal and lysosomal markers. Together, our results support a direct role for ZW10 in interphase dynein-mediated transport. Based on its role at the kinetochore, we propose that ZW10 may represent a novel and general interphase cargo anchor for dynein. Supp. by GM47434 to RBV

### Dynein Light Intermediate Chains: A Comparison of Distribution and Function in Fibroblasts and Developing Neurons

S. C. Tan, J. Tsai, G. Seale, R. B. Vallee; Department of Pathology, Columbia University, New York, NY

Cytoplasmic dynein is a multi-subunit molecular motor complex involved in retrograde vesicular organelle transport, cell migration, and mitosis. Dynein consists of the catalytic heavy chains, intermediate chains, light chains, and two light intermediate chains: LIC1 and LIC2. LIC1 was found to directly bind the centrosomal protein pericentrin (Purohit et al, 1999), indicating a role in mediating at least one form of dynein cargo-binding. The aim of this work is to determine the complete range of light intermediate chain functions as well as the individual and specific roles of LIC1 and LIC2. We have generated three LIC antibodies, which recognize respectively, LIC1, LIC2, and LIC1 and LIC2 together (Tynan et al, 2000). We examined and compared the subcellular localization of LIC1 and LIC2 within both fibroblasts and embryonic rat dissociated neurons and found LIC1 and LIC2 to have both unique and overlapping localization patterns. Distinct LIC1 and LIC2 puncta were seen in double-labeled dissociated neurons with LIC1 enriched at neurite tips while LIC2 was not. In fibroblasts, both LIC1 and LIC2 are localized to centrosomes and mitotic kinetochores. Overexpression of one LIC displaced the other from mitotic kinetochores. RNAi knockdown of LIC1 resulted in defective migration

of neural precursor cells while this process was unaffected by knockdown of LIC2. Together, these findings indicate that the LICs are not only important and necessary for certain dynein-dependent processes, but may have properties and roles specific to individual isoforms, allowing for more refined modulation of dynein function. Supp. by GM47434 to RBV.

**A Role for Huntingtin in Dynein/Dynactin-Mediated Vesicle Trafficking**

J. P. Caviston, S. M. Antony, M. K. Tokito, E. L. F. Holzbaur; Physiology, University of Pennsylvania School of Medicine, Philadelphia, PA

Cytoplasmic dynein is a multi-subunit microtubule motor complex that, together with the dynein activator dynactin, actively drives vesicular cargo towards the minus-ends of microtubules. The mechanism by which dynein targets vesicular cargo is not fully understood. Htt is a vesicle-associated protein thought to play a role in vesicular transport. Polyglutamine repeat expansion in mutant htt causes the neurodegenerative disorder Huntingdon's Disease. However, htt is found in both neuronal and non-neuronal cells and loss of htt results in embryonic lethality in mice, suggesting that htt has an essential function. Mutant htt disrupts axonal trafficking in neurons, indicating that dynein-mediated trafficking may be compromised in the presence of mutant htt and huntingtin-associated protein 1 (HAP-1) interacts with dynactin, suggesting that htt and dynein/dynactin may function in similar pathways in the cell. We hypothesize that htt participates in cargo recruitment for dynein-mediated vesicle transport. In this study, we show that wild-type htt copurifies on vesicles with cytoplasmic dynein and dynactin. In a 2-hybrid screen, we identified Huntingtin (htt) as binding partner for dynein intermediate chain (DIC). By affinity chromatography, we detected an interaction between DIC and both *invitro* translated htt and htt derived from rat brain cytosol. Affinity-tagged htt associated with dynein and dynactin subunits purified from mouse and bovine brain. Immunocytochemistry revealed that htt colocalizes with microtubules in COS7 cells. Htt distribution overlaps with dynein and is concentrated in the Golgi complex. RNAi of htt resulted in Golgi disruption in a manner similar to the disruption of the Golgi that results when the dynein/dynactin interaction is compromised. Together, these findings implicate a role for htt in dynein/dynactin-mediated vesicle trafficking, possibly as an attachment protein that links vesicular cargo to dynein. Supported by NIH GM48661.

**Multiple Effects of LIS1 RNAi on Neural Progenitor Cell Division, Polarization, Aonogenesis, and Motility**

J. Tsai,[1] Y. Chen,[1] A. R. Kriegstein,[2] R. B. Vallee[1]; [1]Department of Pathology and Cell Biology, Columbia University, New York, NY, [2]Program in Developmental and Stem Cell Biology, UCSF, San Francisco, CA

Mutations in the human LIS1 gene cause classical lissencephaly (smooth brain), which has been proposed to result from neuronal migration defects. LIS1 functions in the cytoplasmic dynein pathway, but its cellular role is only partially understood. To explore the detailed mechanisms underlying this disease, we conducted the first *in situ* live-cell imaging analysis of LIS1-deficient neural progenitors throughout the entire radial migration pathway, which involves a series of polarization and repolarization steps. *In utero* electroporation of LIS1 shRNA-expressing cDNAs arrested cells at three morphological stages. The highly asymmetric radial glial cells from which neurons are generated retained their morphology, but interkinetic nuclear oscillations were arrested. Mitotic division in these cells, which occurs at the ventricular surface, was abolished, suggesting the polarized distribution of an unidentified mitotic signal. Most cells accumulated within the subventricular zone with a multipolar morphology. A single axon was produced as in normal cells, but its elongation and the conversion of the multiple processes to a single, thick dominant migratory process were abolished. Finally, the few cells that reached the intermediate zone exhibited normal bipolar morphology. However, somal translocation was arrested, while growth of the migratory process persisted. Together, these data reveal that LIS1 and, presumably, cytoplasmic dynein, direct a complex series of morphogenetic changes during neurogenesis, and have strikingly distinct roles in different process types. Also, despite the importance of LIS1 in this pathway, striking aspects of subcellular polarization persist in its absence. Our results appear to identify a novel mechanism by which nuclear position within radial glial progenitors controls their division. We are exploring this possibility further, and we are testing the role of other dynein regulatory proteins, such as NudE, in the neurogenesis pathway. *Supported by HD40182RBV, NS21223, NS35710 ARK.*

**A G59S Mutation in Dynactin That Causes Motor Neuron Degeneration Induces Protein Aggregation**

J. R. Levy,[1] C. J. Sumner,[2] M. K. Tokito,[1] K. E. Wallace,[1] K. H. Fischbeck,[2] E. L. F. Holzbaur[1]; [1]University of Pennsylvania, Philadelphia, PA, [2]NINDS, Bethesda, MD

Cytoplasmic dynein is the major microtubule minus end-directed motor in the cell. Dynactin is a required activator for dynein-driven processes, including vesicular transport, organelle localization, and mitotic spindle assembly. A G59S missense mutation in the human gene encoding the $p150^{Glued}$ subunit of dynactin results in an autosomal dominant, slowly progressive motor neuron disease. In this study, we examined the biochemical and cellular effects of this mutation. While the mutation affects microtubule binding, it also induces aggregation of $p150^{Glued}$. Sucrose density gradient centrifugation of cell lysates expressing mutant protein shows $p150^{Glued}$ in the 19S fraction, as expected due to the high mass of the dynactin complex. However, the mutant protein reveals a shift to higher density fractions as well, consistent with aggregation leading to heavier complexes. In addition, coimmunoprecipitation of differentially tagged constructs expressed *in vitro* demonstrate aggregation of the G59S polypeptide but not wild type $p150^{Glued}$. Immunofluorescence analysis of cells expressing the G59S mutation indicates the formation of both large, perinuclear, as well as small, cytoplasmically dispersed aggregates. Both dynein and dynactin are recruited to these aggregates; large aggregates also sequester mitochondria. Higher resolution imaging by electron microscopy reveals that the aggregates have a homogenous granular quality and are not membrane-bound. These data are consistent with the disease pathology, as immunohistochemical studies show cytoplasmic dynein- and dynactin-containing inclusions in motor neurons of brainstem tissue from an affected individual. Overexpression of the molecular chaperone Hsp70 inhibits the formation of aggregates in cells expressing the mutant protein, consistent with the hypothesis that the aggregates result from misfolding of the mutant protein and that enhanced aggregation of the mutant proteins leads to motor neuron degeneration in individuals expressing the G59S mutation of $p150^{Glued}$. ## Regulation of Cytoplasmic Dynein ATPase by Lis1

M. T. Mesngon,[1] C. Tarricone,[2] S. Hebbar,[1] A. M. Guillotte,[1] E. Schmitt,[3] L. Lanier,[4] A. Musacchio,[2] S. J. King,[3] D. S. Smith[1]; [1]Biological Sciences, University of South Carolina, Columbia, SC, [2]Department of Experimental Oncology, European Institute of Oncology, Milan, Italy, [3]Division of Mol. Biology and Biochemistry, University of Missouri-Kansas City, Kansas City, MO, [4]Department of Neuroscience, University of Minnesota, Minneapolis, MN

Mutations in Lis1 cause classical lissencephaly, a developmental brain abnormality characterized by defects in neuronal positioning. Over the last decade, a clear link has been forged between Lis1 and the microtubule motor cytoplasmic dynein. Substantial evidence indicates that Lis1 functions in a highly conserved pathway with dynein to regulate neuronal migration and other motile events. Lis1 interacts directly with dynein, but the mechanistic significance of this interaction is not well understood. We now report that recombinant Lis1 increases the microtubule-stimulated enzymatic activity of native brain dynein in vitro. To our knowledge, this is the first indication that Lis1 or any other factor directly modulates the enzymatic activity of cytoplasmic dynein. Binding and colocalization studies indicate that Lis1 associates with only a minor subset of dynein complexes. We propose a model in which the interaction between Lis1 and dynein stimulates a significant increase in the activity of individual motors. This would be particularly useful in neurons, which place high demands on motors for long distance axonal transport.

## CLIP-170 Homolog and NUDE Play Overlapping Roles in NUDF Localization in *Aspergillus nidulans*

V. P. Efimov,[1] J. Zhang,[2] X. Xiang[2]; [1]UMDNJ-Robert Wood Johnson Medical School, Piscataway, NJ, [2]USUHS, Bethesda, MD

Several proteins involved in cytoplasmic dynein functions track the plus ends of microtubules when observed in live cells (reviewed by Carvalho *et al*., 2003). Among them, NUDF of *Aspergillus nidulans* (Lis1/Pac1) is a key component of the dynein pathway (Han *et al*., 2001). How NUDF is targeted to the microtubule plus end was unclear. Both CLIP-170 and NUDE physically interact with NUDF or its homologs and therefore are potential candidates for NUDF-targeting proteins (Efimov and Morris, 2000; Coquelle *et al*., 2002; Sheeman *et al*., 2003; Lansbergen *et al*., 2004). Here we investigate the *A. nidulans* homolog of CLIP-170, CLIPA. CLIPA has one CAP-Gly domain at the N-terminus and two zinc finger motifs at the C-terminus. GFP-CLIPA was observed in moving comets, representing its association with the growing microtubule plus ends. This localization was not dependent upon NUDA (dynein heavy chain), NUDF or the KipA kinesin (homolog of Kip2/tea2p) (Konzack *et al*., 2005). The *clipA* deletion mutant exhibited only a mild growth defect, and unlike the situation in yeasts (Berlin *et al*., 1990; Brunner and Nurse, 2000), cytoplasmic microtubules did not appear to be abnormally short and instead they clearly reached the hyphal tip. Combined with the *nudE* deletion mutant that also showed a mild growth phenotype, the double mutant exhibited a more dramatic growth defect. Deletion of both *clipA* and *nudE* almost completely abolished NUDF comets at the hyphal tip, while this dramatic effect was not observed in either single deletion mutant grown under the same condition. Thus, CLIPA and NUDE play overlapping roles in NUDF's plus-end targeting. Dynein comets were clearly present in the absence of both CLIPA and NUDE, demonstrating that different mechanisms are used for targeting dynein and NUDF in *A. nidulans*.

207

## The Role of NudE and NudEL in Mitotic Progression

S. A. Stehman, Y. Chen, R. B. Vallee; Pathology, Columbia University, New York, NY

NudE and NudEL are two closely related dynein regulatory proteins that interact with both the dynein complex and LIS1, a distinct dynein regulator responsible for the brain developmental disease lissencephaly. In contrast to cortical disorganization caused by LIS1 deficiency, NudE knockout mice exhibit a microcephalic phenotype (Neuron 44:279). The extent to which these outcomes reflect defects in neural cell migration vs. division has been the subject of debate (Tsai, J-W., et al., J. Cell Biol., in press). The current study seeks to determine common and distinct functional properties of NudE, NudEL, and LIS1, with an emphasis on mitosis. In previous work we observed NudE/L at the leading edge of migrating fibroblasts, a known site of dynein and LIS1 localization (J. Cell Biol. 163:1205), and showed that interference with NudE/L function blocked directed cell migration (Mol. Biol. Cell 15:394a). We also found NudE and NudEL to localize to mitotic kinetochores prior to dynein and LIS1 and remain at these sites until early anaphase, well after dynein, dynactin, and LIS1 had moved to the spindle poles (Mol. Biol. Cell 15:394a). In further contrast to LIS1, dynein, and dynactin, NudE/NudEL were absent from the mitotic cell cortex. Recent work from our lab has sought to explore these differences to determine how NudE and NudEL function in mitotic progression. Mitotic cells were injected with an anti-NudE/L antibody found to specifically interfere with the interaction between NudE/L and dynein. 60% of injected cells exhibited a mitotic defect, with an average duration for prometaphase-metaphase of 41.6 min compared. 24 min for controls. Further analysis is underway to test in detail at which stages of mitosis NudE and NudEL function. Supp. by HD40182 to RBV.

## Regulated Microtubule-binding of P150$^{Glued}$ And Search-capture

M. T. Raycroft, P. S. Vaughan, K. T. Vaughan; Biological Sciences, University of Notre Dame, Notre Dame, IN

Microtubule (MT) tip-tracking is a unique behavior thought to reflect the dynamic association of some search-capture candidates with MT plus-ends. Phosphorylation has been implicated as one mechanism of release, however other mechanisms are also under investigation. To explore novel aspects of this phosphorylation model, we have analyzed the lagging recruitment of kinases, the impact of p150$^{Glued}$ mutants in the MT- binding domain, and coordination of other tip-tracking proteins. Our lab has proposed that lagging recruitment of MAPs and MT-bound kinases is the basis of MT plus-end specificity in overexpression experiments using GFP-tagged p150$^{Glued}$ expression constructs. To test the MAP recruitment model, we co-transfected MAP4 with CLIP-170 or p150$^{Glued}$ to reveal possible differences in MT-binding kinetics. MAP4 decorated the MT lattice with reduced labeling at the MT-tip, suggesting that MAPs display some lag in recruitment to the MT wall when compared to tip-tracking proteins of interest (CLIP-170 or p150$^{Glued}$). The G59S mutation in the MT-binding domain of p150$^{Glued}$, which is linked to human late-onset motor neuron disease, was engineered into GFP-p150$^{Glued}$ fusion constructs and tested by live-cell imaging. Wild-type p150$^{Glued}$ normally tip-tracks, while the G59S mutant failed to label MTs. To further test the impact of this mutation, we co-transfected siRNA (for endogenous p150$^{Glued}$) and GFP-G59S-p150$^{Glued}$. Unlike the wild type protein, the mutant construct was not able to rescue normal dynein-driven transport, and it also inhibited mitotic progression. Live-imaging was used to visualize GFP-p150$^{Glued}$with mRFP-EB1 or mRFP-CLIP-170. Our assays indicate that EB1, p150$^{Glued}$ and

CLIP-170 tip-track on the same MTs, and combined data from these co-transfection experiments suggest that there is a hierarchy of loading at the MT-tip. The MT-binding of p150$^{Glued}$ is a dynamic, regulated process providing valuable insight into search-capture components and dynein-mediated transport. (Supported by NIH GM60560).

### Function Evidence and Regulation of Tctex-1 Mediated Apical Transport in Polarized Epithelial Cells and Mammalian Photoreceptors

T. Yeh, J. Chuang, C. Sung; Ophthalmogy, Dyson Vision Research Institute, Weill Medical College of Cornell University, New York, NY

Cytoplasmic dynein plays a crucial role for the microtubule-based membrane vesicle trafficking, but its regulatory mechanism remains largely unknown. Our previous in vitro studies suggested that Tctex-1, a light chain of cytoplasmic dynein, functionally interacted with the C-terminus of rhodopsin. Subsequent studies showed that Tctex-1 mediated dynein motor activity was involved in the apical translocation of rhodopsin in polarized MDCK cells. Here, using a recently developed retinal transfection method, we showed that rhodopsin was mislocalized in mouse photoreceptors in which Tctex-1 was suppressed by siRNA. These results provide in vivo evidence that Tctex-1 mediates the polarized outer segment targeting of rhodopsin in rod photoreceptors. In addition, we identified a potential phosphorylation site within the region where Tctex-1 previously mapped to interact with dynein intermediate chain (IC). In vitro binding assays showed that the phosphomimic Tctex-1 mutant (i.e. E mutant) bound to rhodopsin, but not IC. The non-phosphomimic Tctex-1 mutant (i.e. A mutant), liked the wild type Tctex-1, bound both IC and rhodopsin. We examined how rhodopsin was targeted in MDCK monolayers inducibly expressing either the wild-type, the E mutant, or the A mutant. Consistent to the previous report, rhodopsin was apically targeted in MDCK cells expressing wild-type Tctex-1. However, rhodopsin was mislocalized to the basolateral surfaces in MDCK cells expressing either the E mutant or the A mutant. The mislocalization was unlikely to be due to the tight junction leak because the transepithelial electric resistance, the paracellular permeability, and the distribution of several other apical (e.g., gp135) and basolateral (e.g., Na+/K+-ATPase) markers appeared to be normal in all these cell lines. Thus, we propose that the dissociation between Tctex-1 and IC plays an important role in regulating dynein-mediated apical targeting in polarized epithelial cells.

### Design of Biomolecular Adaptors for retrograde Transport (BART) for the Transport of Novel Cargo by Dynein

R. N. Cohen,[1] M. J. Rashkin,[2] F. C. Szoka[1,2]; [1]Joint Graduate Group in Bioengineering, UC San Francisco/UC Berkeley, San Francisco, CA, [2]Biopharmaceutical Sciences, UC San Francisco, San Francisco, CA

The cytoplasm of a eukaryotic cell is a crowded, viscous milieu consisting of proteins, organelles, and RNA, which limit the diffusion of macromolecules. In order to generate and maintain intracellular organization, cells have evolved a system of molecular motors capable of moving large cellular components (cargo) from place to place along molecular filaments. For long distance transport, cytoplasmic dynein carries its cargo towards the microtubule minus end in the cell interior (retrograde) and kinesin carries its cargo towards the microtubule plus end in the cell periphery (anterograde). Our expanding knowledge of how these motors function and how they bind to their respective cargos makes it increasingly feasible to utilize the intracellular transport system for novel applications. We are attempting to target macromolecules or particles to dynein to increase the intracellular mobility of and the retrograde transport of novel cargos. A primary application for this technology is the delivery of DNA towards the nucleus for gene therapy. We have synthesized a small (22 amino acids) adaptor peptide that binds to the light chain 8 (LC8) of dynein to mediate the attachment of novel cargo to dynein. We designate this peptide a Biomolecular Adaptor for Retrograde Transport, or BART. Binding of LC8 to this peptide but not to a similar peptide with just 2 amino acids mutated has been confirmed by an affinity pull-down assay. A BART peptide that binds instead to a different dynein light chain, tctex1, is currently being designed. These peptides will be used in transport and particle tracking studies to determine if they can target conjugated cargo to dynein for transport to the cell interior.

211

### The Role of Cytoplasmic Dynein in Adenovirus Transport

K. H. Bremner, R. B. Vallee; Pathology, Columbia University, New York, NY

The minus end-directed microtubule motor cytoplasmic dynein transports a range of subcellular cargoes. It has also has been implicated in the translocation of various viruses to the nucleus, including adenovirus, a commonly used gene delivery vector with a relatively simple capsid composition [JCB 144:657-72 1999; Hum. Gene Ther. 11:151-65 2000]. The aim of the present study was to examine the molecular basis of the adenovirus 5-dynein interaction and therefore further our understanding of the mechanism and regulation of dynein cargo binding. Post-endocytic virus in synchronously infected cells was imaged by confocal microscopy at 60 minutes post-infection. We observe colocalization of the dynein heavy chain and light intermediate chains, as well as the dynactin p150$^{Glued}$ and Arp1 subunits, with incoming adenovirus capsids, including those bound to the nuclear envelope. We find that dynein, though not dynactin, co-immunoprecipitates with physiologically processed adenovirus particles recovered from infected cells, suggesting distinct roles for dynein and dynactin in adenovirus transport. We also find that the novel dynein regulatory proteins NudE/NudEL and NudC exhibit striking colocalization with incoming adenovirus, whereas LIS1 and ZW10 do not. Together, our data provide evidence for extensive utilization of the host cell dynein pathway by adenovirus. Supported by NIH grant GM47434 (RV) and an AHA postdoctoral fellowship (KB).

## Microtubule-Associated Proteins (212-237)

212

### Molecular Mechanisms of Microtubule Plus End Tracking Proteins

K. C. Slep,[1,2] R. D. Vale[1,2]; [1]Cellular & Molecular Pharmacology, University of California San Francisco, San Francisco, CA, [2]Howard Hughes Medical Institute, University of California San Francisco, CA

The Xmap215, Clip-170 and EB1 protein families represent distinct classes of microtubule associated protein that track along the tips of growing microtubules and that control microtubule dynamics, and mitotic spindle structure. To gain a better mechanistic understanding of how these proteins work, we have solved the crystal structures of the putative tubulin binding domains of Xmap215, Clip-170 and EB1. These atomic structures reveal distinct and unrelated protein folds, but in each case, amino acid conservation maps and mutagenic analyses reveal a conserved

face that appears to be responsible for tubulin association. To better understand how these domains operate, we have performed in vitro tubulin binding and nucleation assays and in vivo expression of GFP fusion proteins. Our results indicate that all of the proteins act as functional dimers. Single domains do not promote nucleation or associate with microtubules in vivo. However, dimerization confers both of these activities. This is dramatically demonstrated by chemical-induced dimerization. Monomeric EB1 or Clip-170 tubulin binding domains fused to FKBP and FRB are diffuse in the cytoplasm, but rapamycin-induced FKBP-FRB dimerization causes rapid relocalization to microtubule plus ends. Surprisingly, even chemical-induced heterodimerization of the structurally unrelated EB1 and Clip-170 binding domains results in microtubule plus end tracking. We propose that a unifying feature of these structurally diverse microtubule plus end tracking proteins is their ability to bind multiple tubulin subunits and deliver them to the plus end of microtubules, thereby allowing them to act as “chaperones” for microtubule polymerization.

213

### Potential APC and EB1 Functions in Scattering MDCK Cells

E. E. Morrison, C. Griffin, K. J. Langford, T. Lee, J. M. Askham; CRUK Clinical Centre at Leeds, Leeds, United Kingdom

The adenomatous polyposis coli (APC) tumour suppressor protein has been suggested to play a role in cell migration by capturing and stabilising microtubules at extending membranes and/or participating in centrosome reorientation towards the cell leading edge in a GSK3beta-dependent manner. We have correlated polarity development and cell movement with APC distribution in MDCKII epithelial cells scattering in response to PMA. Migratory polarity arose from the formation of a broad leading edge lamellipodium and rear retraction. The centrosome and Golgi apparatus were located towards the rear of migrating cells and stable microtubules were concentrated in retraction tails. Immunostaining indicated that APC clustered at the tips of retraction tails and the lateral margins of leading edge lamellipodia. This was confirmed by live imaging of cells expressing a GFP-APC fusion protein. Furthermore, live imaging of cells stably expressing EB1-GFP, an APC ligand, revealed the existence of novel, relatively immobile EB1-GFP structures at the cell periphery in both control and scattering cells that co-localised with APC in fixed cells. These structures may represent sites of active linkage between APC, EB1 and microtubule ends. Although closely juxtaposed, APC cortical clusters did not co-localise with focal adhesions but they defined cortical sites resistant to Latrunculin A-induced peripheral retraction. APC peripheral clusters were larger in cells expressing EB1-GFP than in control cells and cells expressing EB1-GFP spread more quickly during the initial stages of the scattering response. However, neither effect was seen in cells stably expressing potential dominant-negative EB1 mutants. Finally, GSK3beta inhibition antagonised APC clustering and morphological polarisation in PMA-treated cells. We propose that APC clusters link microtubules, via EB1, to stable, adhesive regions of the cell cortex that resist retraction during PMA-induced epithelial cell scattering.

214

### Structural Basis for the Activation of Microtubule Assembly by the EB1 and p150$^{Glued}$ Complex

I. Hayashi,[1] A. Wilde,[2] T. K. Mal,[1] M. Ikura[1]; [1]Department of Medical Biophysics, University of Toronto, Ontario Cancer Institute, Toronto, ON, Canada, [2]Department of Medical Genetics and Microbiology, University of Toronto, Toronto, ON, Canada

Plus-end tracking proteins, such as EB1 and the dynein/dynactin complex, regulate microtubule dynamics. These proteins are thought to stabilize microtubules by forming a plus-end complex at microtubule growing ends with ill-defined mechanisms. Here we report the crystal structure of two plus-end complex components, the carboxy-terminal dimerization domain of EB1 and the microtubule-binding (CAP-Gly) domain of the dynactin subunit p150$^{Glued}$. Each molecule of the EB1 dimer contains two helices forming a conserved four-helix bundle, while also providing p150$^{Glued}$-binding sites in its flexible tail region. Combining crystallography, NMR and mutational analyses, our studies reveal the critical interacting elements of both EB1 and p150$^{Glued}$, whose mutation alters microtubule polymerization activity. Moreover, removal of the key flexible tail from EB1 activates microtubule assembly by EB1 alone, suggesting that the flexible tail negatively regulates EB1 activity. We, therefore, propose that EB1 possesses an autoinhibited conformation which is relieved by p150$^{Glued}$ as an allosteric activator.

215

### The Microtubule Plus End-Binding Protein EB3 is Essential for Muscle Cell Differentiation

A. Straube,[1] A. Merdes[2]; [1]Wellcome Trust Centre for Cell Biology, University of Edinburgh, United Kingdom, [2]CNRS - Pierre Fabre, Toulouse, France

Upon muscle cell differentiation, myoblasts elongate and fuse at their cell poles with each other to form large multinuclear myotubes. This process involves a striking reorganization of the microtubule cytoskeleton. Microtubules align along the length of the cell while centrosomes disassemble and centrosomal proteins are recruited to the nuclear surface. We identified the microtubule plus end-binding protein EB3 as a key player in these processes. Although EB3 is expressed only at very low levels in undifferentiated myoblasts, its depletion using specific shRNAi constructs results in many curly microtubules. In contrast, depletion of the abundant and closely related protein EB1 has no obvious effects on the microtubule organization. However, depletion of both EB1 and EB3 enhances the curly microtubule phenotype, indicating that EB1 can partially rescue the loss of EB3. EB3 is upregulated early during muscle differentiation, suggesting that it fulfils an important role during cell polarisation and microtubule reorganization. Indeed, depletion of EB3 prevents myoblast fusion. EB3 depleted cells show defects in bipolar cell elongation and microtubule organization. As cell migration was not compromised we speculate that microtubule-dependent signalling at the cell poles might be affected in EB3-depleted cells. Experiments are under way to examine the mechanisms by which EB3 helps to accomplish muscle cell differentiation.

### Mal3p, the *S pombe* Homolog of EB1, Localizes Preferentially to the Microtubule Lattice Seam

L. Sandblad,[1] K. E. Busch,[2] P. Tittmann,[3] H. Gross,[3] D. Brunner,[2] A. Hoenger[1]; [1]SBBC, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany, [2]CBB, EMBL, Heidelberg, Germany, [3]Electron Microscopy Center ETH Zurich, Swiss Federal Institute of Technology, Zurich, Switzerland

*In vivo* dynamics and spatial organization of Microtubules (MTs) are regulated by highly conserved Microtubule-associated proteins (MAPs), e.g. end-binding protein1 (EB1). We are investigating the structure and function of MTs complexes with a subset of MT plus end interacting proteins (+TIPs), using *in vitro* assays and electron microscopy. The *S. pombe* protein Mal3p belongs to the EB1-family, and is a central component in the polarity determination mechanism. Mal3p, like its human homolog EB1, was previously reported to bind MT plus ends and after over expression

also to the MT lattice. With high-resolution surface shadowing electron microscopy we found Mal3 binding on the MT surface in an interesting manner, never demonstrated for any other MAPs before. Mal3p preferentially binds along one single groove in between two protofilaments. The binding sites repeat with 8 nm intervals, corresponding to the length of a αβ-tubulin dimer. Geometrical analyses of the Mal3p-MT interaction show a pattern according to a MT A-lattice, the tertiary conformation of the MT lattice seam. Our findings suggest that Mal3p regulates MT dynamics through a specific interaction with the MT lattice seam. Furthermore, we currently investigate the interaction between MTs, Mal3p and other +TIPs, to gain insight into the structure and function of these complexes. Tip1p, the *S. pombe* homolog of CLIP170 and the kinesin like motor protein Tea2p are both dependent on Mal3p for proper interaction with MTs and their transport to the growing plus end.

**The Role Of Plus-end-tracking Proteins (+tips) In Dynein-mediated Endosome Traffic**

J. H. Lenz, I. Schuchardt, G. Steinberg; Department of Organ. Interactions, Max Planck Institute of Terrestrial Microbiology, Marburg, Germany

In higher eukaryotes endosome motility is mediated by microtubule-dependent motors. We have previously shown that minus-end directed dynein participates in bidirectional traffic of early endosomes (EE) in yeast-like cells of the model fungus *Ustilago maydis*. Here we demonstrate that dynein supports retrograde long-distance transport of EE in the elongated hyphae. Most dynein localizes to the microtubule (MT) plus-ends in the hyphal tip. Life cell imaging revealed that EE migrate into this dynein accumulation before they reverse direction. Thus, the apical concentration might be a reservoir of inactive motors that become loaded with EE at MT plus-ends and become activated for minus-end directed organelle traffic. Consistent with this notion, in null mutant hyphae of *kin1*, a Kinesin-1 that targets dynein to the plus-ends in *U. maydis*, retrograde EE traffic is abolished. Furthermore, depletion of the putative dynein activator LIS1, which colocalizes with dynein at MT plus-ends, significantly increases the amount of dynein in the tip and abolished retrograde EE traffic. Surprisingly, neither EE motility nor dynamic instability of MTs was affected in mutants deleted in a CLIP-170 homologue. These findings contradict the assumed role of this +TIP in anchoring EE and dynein at the MT tip. Instead, our results indicate that dynein is anchored at the plus-ends by a yet unknown mechanisms that might involve the dynactin complex. Further studies are underway that address the role and localization of dynactin in retrograde, dynein-dependent EE transport.

218

**Phosphorylation Regulates CLIP-170 Conformation and Kinetics**

H. Lee,[1] E. S. Nadezhdina,[2] Y. A. Komarova,[1] G. G. Borisy[1]; [1]Cell and Molecular Biology, Northwestern University, Chicago, IL, [2]Institute of Protein Research, Moscow, Russian Federation

Cytoplasmic Linker Protein 170 (CLIP-170) is a microtubule plus end-tracking protein which binds to growing microtubule plus ends. CLIP-170 conformation switches between "open" and "closed states via an intramolecular association between its $NH_2$-terminal head and COOH-terminal tail and regulates its binding to microtubules and dynactin (Lansbergen et al., JCB 2004). Here we show that the intramolecular association is regulated by phosphorylation. Addition of the third serine-rich region to the head domain of CLIP-170 diminished its ability to interact with the CLIP-170 tail in a co-immunoprecipitation assay. This effect was relieved by treatment of cells with the de-phosphorylation-inhibiting drug, okadaic acid, suggesting that phosphorylation of residues located in the third serine-rich region are important for stabilizing the CLIP-170 folded conformation. To determine the potential regulatory sites involved in the head-to-tail interaction, we performed in-vitro site-directed mutagenesis on 16 conservative serines located in the third serine-rich region, and analyzed head-tail interaction by domain co-immunoprecipitation assays. We identified four key serine residues: S311, S313, S319 and S320. Mutation of these residues to Ala which mimics the dephosphorylated state resulted in disruption of the head-to-tail interaction while mutation of the same residues to Glu which mimics the phosphorylated state stabilized this interaction. The ala mutants also induced more efficient binding of full length CLIP-170 to taxol-stabilized microtubules compared to the Glu mutant or wild-type CLIP-170 in a microtubule-pelleting assay suggesting that dephosphorylated CLIP-170 has higher affinity for the microtubule lattice. Consistent with this result, YFP-CLIP-170-Ala mutant dissociated twice slower from the growing plus ends of microtubules in vivo whereas YFP-CLIP-170-Glu dissociated twice faster than wild-type CLIP-170. We conclude that critical serine residues control CLIP-170 conformational transitions and their phosphorylations are essential in order to ensure stable interaction between the head and tail. Supported by NIH GM25062 to GGB.

**The Minimal Functional Unit for CLIP-170 Plus-End Tracking**

E. S. Folker, H. V. Goodson; Biochemistry, University of Notre Dame, Notre Dame, IN

Because the molecular events at the microtubule plus-end govern whether a microtubule will grow or shrink, the proteins that localize specifically to this region are likely to play a role in the regulation of the microtubule cytoskeleton. The answer to *how* these proteins localize to the plus-end will probably provide insight into the *why* these proteins track microtubule plus-ends. We have recently provided evidence that CLIP-170 uses a preassociation and copolymerization mechanism to track microtubule plus-ends. However yeast CLIP-170 orthologs track microtubule plus-ends by a kinesin dependent mechanism, suggesting that other mechanisms might contribute to CLIP-170 plus-end tracking behavior . To address this and other questions about the CLIP-170 +TIP behavior, truncations of CLIP-170 were made to separate the two conserved CAP-Gly domains. The abilities of each construct to track microtubule plus-ends, bind tubulin, bind microtubules, and bind EB1 were then tested. These analyses lead to the following conclusions. First, the ability of CLIP-170 to bind tubulin with high affinity is not sufficient for CLIP-170 to track microtubule plus-ends, and may not be required. However, tracking in the absence of a high affinity interaction with tubulin is rare, spatially constrained, and not obvious. Moreover, constructs that do bind tubulin with high affinity track microtubule plus-ends most robustly. Second, binding to EB1 likely contributes to, but is not sufficient for CLIP-170 +TIP behavior in the absence of a high affinity interaction with tubulin. Finally, the first CAP-Gly is required for CLIP-170 plus-end tracking behavior. These findings suggest that cellular conditions add complexity to the previously described preassociation and copolymerization mechanism for CLIP-170 plus-end tracking behavior.

**The CLIP170 Homologue Bik1p, the cyclin Clb5p, and Kar9p Phosphorylation in Yeast**

J. K. Moore, S. D'Silva, R. K. Miller; Department of Biology, University of Rochester, Rochester, NY

Accurate positioning of the mitotic spindle in *S. cerevisiae* is coordinated with the asymmetry of the two poles and requires the microtubule-to-actin linker, Kar9p. The asymmetric localization of Kar9p to one SPB and microtubule (MT) plus ends requires Cdc28p, the yeast Cdk1. Here, we show that the CLIP170 homologue, Bik1p, binds directly to Kar9p. In the absence of Bik1p, Kar9p localization is not restricted to the daughter-bound SPB, but is instead found on both SPBs. *bik1Δ* mutants also exhibit a defect in SPB inheritance that is proportional to the percentage of cells in which Kar9p localizes to both poles. Kar9p is hypo-phosphorylated in *bik1*Δ mutants and Bik1p binds to both phosphorylated and unphosphorylated isoforms of Kar9p. Furthermore, the two-hybrid interaction between full length *KAR9* and the cyclin *CLB5* requires *BIK1*. The binding site of Clb5p on Kar9p maps to a short region within the basic domain of Kar9p that that is adjacent to the binding site for Bik1p and contains a conserved phosphorylation site, serine 496. Mimicking phosphorylation at this residue with a S496E mutation restores Kar9p-GFP localization to one SPB in both *bik1*Δ and *clb5*Δ cells. Together, these data suggest that Bik1p promotes the phosphorylation of Kar9p by facilitating the Kar9p-Clb5p interaction, which in turn restricts Kar9p to one SPB and associated cytoplasmic microtubules. These findings provide further insight into a mechanism for directing centrosomal inheritance.

### Kar9p Interacts with Smt3p and the Machinery for Sumoylation in Yeast

N. Meednu,[1] H. Hoops,[2] L. Jablonski,[1] E. Sia,[1] R. K. Miller[1]; [1]Department of Biology, University of Rochester, Rochester, NY, [2]Department of Biology, State University of New York, Geneseo, NY

Kar9p plays an important role in positioning the mitotic spindle by serving as a linker between the actin and microtubule cytoskeletons. The microtubule-to-Kar9p linkage occurs through Bim1p, a microtubule binding protein and EB1 homologue. However, little is known about the molecular mechanisms that regulate Kar9p function. SUMO/Smt3p is a conserved small ubiquitin-related modifier that is covalently attached to other proteins as a post-translational modification. SUMO is analogous to ubiquitin in several ways, but functionally different. Unlike ubiquitin, sumoylation does not target proteins for degradation. Although the targets of sumoylation are associated with a diverse set of biological processes, it was not previously known whether sumoylation regulates the microtubule-dependent process of spindle positioning in yeast. Here, we show that Kar9p and Bim1p are likely to be modified by SUMO/Smt3p. Both interact with *SMT3* by two-hybrid analysis. However, neither interact with a mutant form of *SMT3* in which the terminal glycine required for conjugation has been mutated to alanine. Both *KAR9* and *BIM1* also interact with proteins involved in the sumoylation pathway-- *UBC9* an E2 enzyme required for SUMO conjution; *NFI1* an E3 enzyme conferring specificity for SUMO targets; and *WSS1* a weak suppressor of SUMO. The Kar9p-Ubc9p interaction was confirmed *in vitro* by affinity chromatography. A single point mutation in *KAR9*, *kar9*-L304P, disrupts the two-hybrid interaction with *SMT3*, *UBC9*, and *WSS1* but retains its interactions with other proteins important for spindle positioning, *BIM1*, *MYO2*, *BIK1*, and *STU2*. Phenotypic analysis of the *kar9*-L304P mutant demonstrates that its spindle is mis-positioned relative to the bud neck. Combined, these data suggest that sumoylation may be a new mechanism for the regulation of Kar9p and Bim1p function during spindle positioning in yeast.

222

### Phosphorylation of CLASP2γ by GSK-3β Regulates the Interaction with IQGAP1

J. Noritake,[1] T. Watanabe,[1] T. Harada,[1] T. Matsui,[1] S. Wang,[1] M. Fukata,[2] K. Kaibuchi[1]; [1]Department of Cell Pharmacology, Nagoya University Graduate School of Medicine, Nagoya, Japan, [2]Laboratory of Genomics and Proteomics, National Institute for Longevity Science, Obu, Japan

Links between the plus-ends of microtubules and cortical regions are essential for the establishment of cell polarity and directional migration. The plus-end-tracking proteins (+Tips) accumulate at the plus-ends of growing microtubules and play pivotal roles in sensing cortical capture sites. CLIP-associating proteins (CLASPs), one of +Tips, are known to regulate the microtubule network cooperating with the cytoplasmic linker proteins (CLIPs) to maintain cellular asymmetry. Recent studies about CLASPs have suggested that Rac1 and GSK-3β regulate the CLASP-microtubule association. Here we found that CLASP2γ formed a quaternary complex with IQGAP1, GTP-bound form of Rac1/Cdc42, and CLIP-170, and colocalized with IQGAP1 at the leading edge of Vero fibroblasts, where specific subsets of microtubules are targeted. Our further analysis revealed that GSK-3β phosphorylated CLASP2γ and the phosphorylation of CLASP2γ inhibited its interaction with IQGAP1. On the other hand, the interaction of CLASP2γ with IQGAP1 was restored by the treatment of GSK-3β inhibitors such as Lithium Chloride and SB21673 in Vero fibroblasts. These results suggest that GSK-3β negatively regulates the interaction of CLASP2γ with IQGAP1, and CLASP2γ stabilizes microtubules at the cell periphery together with IQGAP1 and CLIP-170.

223

### Spatial Regulation of CLASP Affinity for Microtubules by Rac1 and GSK3ß in Migrating Epithelial Cells

T. Wittmann, C. M. Waterman-Storer; Cell Biology, The Scripps Research Institute, La Jolla, CA

Cell locomotion depends on polarization of the cytoskeleton including actin and microtubules. We previously observed that microtubule dynamic instability is locally regulated in migrating cells downstream of the small GTPase Rac1 (*J. Cell Biol.* **161**:845-851), a regulator of actin polymerization dynamics in migrating cells. Proteins that in cells specifically bind to growing microtubule plus ends (+TIPs) are thought to play important roles in polarization of the cytoskeleton. However, most +TIPs such as EB1 and CLIP-170 do not show a bias of their microtubule-binding behavior toward different subcellular regions. Here, we examine the dynamics of the +TIP CLASP (mammalian homologue of *Drosophila* orbit/mast) in migrating PtK1 epithelial cells (*J. Cell Biol.* **169**:929-939). We find that, although CLASPs track microtubule plus ends in the cell body, they decorate the entire microtubule lattice in the leading edge lamella. FRAP reveals fast turnover of CLASP on lamella microtubule lattices. Rapid recovery of CLASP fluorescence also occurred just behind the growing microtubule plus end in the cell body, which has implications for the CLASP plus end-loading mechanism. Microtubule lattice binding is mediated by the COOH-terminal region of the CLASP microtubule-binding domain, which is also required for high affinity binding to taxol-stabilized microtubules in vitro. Microtubule lattice binding is regulated downstream of Rac1 and glycogen synthase kinase 3β (GSK3β). Phosphorylation of sites in the N-terminal part of the CLASP microtubule-binding domain by GSK3β likely regulates the affinity of CLASPs for microtubule lattices. These results demonstrate the striking difference of the microtubule cytoskeleton in the lamella as compared with the cell body and provide the first direct observation of subcellular regulation of a microtubule-associated protein in migrating cells. These results also suggest a complex, local regulation of CLASP affinity for microtubules.

224

**CLAMP, A Novel Microtubule-Associated Protein with EB-Type Calponin Homology**

G. W. Dougherty,[1] H. J. Adler,[2] A. Rzadzinska,[3] M. Gimona,[1] Y. Tomita,[4] C. Lattig,[5] R. Merritt,[6] B. Kachar[6]; [1]Cell Biology and Oncology, Consorzio Mario Negri Sud, Santa Maria Imbaro, Chieti, Italy, [2]Biology, University of Maryland, College Park, MD, [3]Genetics of Deafness, Wellcome Trust Sanger, Cambridge, United Kingdom, [4]Lombardi Cancer Center, Georgetown University, NW Washington, DC, [5]G-Protein Coupled Receptors, NINDS / NIH, Bethesda, MD, [6]Cell Structure, NIDCD / NIH, Bethesda, MD

Microtubules (MTs) are polymers of α and β tubulin dimers that mediate many cellular functions, including the establishment and maintenance of cell shape. The dynamic properties of MTs may be influenced by tubulin isotype, post-translational modifications of tubulin, and interaction with microtubule-associated proteins (MAPs). End-Binding (EB) family proteins affect MT dynamics by stabilizing MTs, and are the only MAPs reported that bind MTs via a calponin-homology (CH) domain (Bu and Su, 2003; Tirnauer and Bierer, 2000). Here we describe a novel 27 kDa protein identified from an inner ear organ of Corti library. Structural homology modeling demonstrates a CH domain in this protein similar to EB proteins. Northern and Western blotting confirmed expression of this gene in other tissues including brain, lung, and testis. In the organ of Corti, this protein localized throughout distinctively large and well-ordered MT bundles that support the elongated body of mechanically stiff pillar cells of the auditory sensory epithelium. When ectopically expressed in Cos-7 cells, this protein localized along cytoplasmic MTs, promoted MT bundling, and efficiently stabilized MTs against depolymerization in response to high concentration of nocodazole and cold temperature. We propose that this protein, designated CLAMP, is a novel MAP and represents a new member of the CH domain protein family.

225

***Adenomatous Polyposis Coli* is Required for Proper Cytokinesis by Affecting Anaphase Spindle Dynamics**

C. M. Caldwell, R. A. Green, K. B. Kaplan; University of California, Davis, Davis, CA

We have shown that mutations in the tumor suppressor gene *adenomatous polyposis coli* (e.g., $APC^{1-1450}$) dominantly inhibit microtubule dynamics and thus compromise chromosome alignment during metaphase (Green and Kaplan 2003, Green et al 2005). In addition, we have observed that expression of $APC^{1-1450}$ results in an accumulation of multinucleated cells. As the cytokinetic furrow has been shown to be specified by anaphase spindle microtubules, we hypothesized that APC mutants that affect spindle dynamics fail to properly regulate cortical activities required for cytokinesis. Consistent with this hypothesis, we observed cytokinetic defects in cells expressing $APC^{1-1450}$. One population of cells initiates anaphase but fails to complete cytokinesis, exiting mitosis and forming binucleate cells. A second population of cells was observed to delay furrow initiation, often forming asymmetric furrows before completing cell division. To address the cause of the cytokinetic defects, we examined the localization of the cytokinetic determinants, Aurora B, RhoA and actin. In cells expressing $APC^{1-1450}$ AuroraB fails to localize properly to the spindle midzone. Similarly, RhoA and actin are also mis-localized; instead of a polarized distribution, RhoA and actin are evenly distributed to the polar and medial cortex in cells expressing $APC^{1-1450}$. These patterns are consistent with the aberrant furrow formation observed and suggest that APC normally regulates the activity and/or position of cytokinetic determinants. Similar cytokinetic defects are observed when microtubule dynamics are inhibited using drug treatment or by inhibiting the plus-end binding protein, EB1. Together, these data suggest that APC modulates microtubule dynamics throughout mitosis and that multiple mitotic defects may contribute to the chromosome instability observed in colorectal tumor cells.

226

**GEF-H1, a Microtubule-Regulated Exchange Factor, Modulates Rho Function Required for Cytokinesis**

J. Birkenfeld, P. Nalbant, B. Bohl, G. M. Bokoch; Immunology, The Scripps Research Institute, La Jolla, CA

Formation of a functional actomyosin contractile ring (cleavage furrow; CF) during cytokinesis requires coordinated cycles of RhoA between the active GTP-bound state and the inactive GDP-bound form. Microtubules (MTs) may play an important role in induction and positioning of the CF by providing a stimulus for the localized activation of RhoA. In this study, we address the role of GEF-H1, a RhoA-specific nucleotide exchange factor that is regulated by MT binding in the localized RhoA activation during cytokinesis. First, we show that perturbation of endogenous GEF-H1 function by both, overexpression of inhibitory mutants and siRNA-mediated gene knock down led to the formation of multinucleated cells, a clear indication of failed cytokinesis. In addition, subcellular distribution of GEF-H1 correlated with the formation of the acto-mysosin CF. We found GEF-H1 immnuoreactivity to accumulate at regions of the mitotic apparatus known to be essential for cytokinesis such as the spindle midzone and the midbody. Furthermore, since GEF-H1 interacted with RhoA during CF formation and ingression (as demonstrated in GST-RhoAT19N pull down assays) and, GEF-H1 depletion caused a dramatic decrease in RhoA activation during telophase (as measured by RBD pull down assays) GEF-H1 enzymatic activity appears to be a crucial factor for localized RhoA activation during cytokinesis.

227

**Regulation of Microtubule Stability *in vitro* and in Transfected Cells by MAP1B and SCG10**

P. Bondallaz,[1] A. Barbier,[1] S. Soehrman,[1] G. Grenningloh,[2] B. M. Riederer[1,2]; [1]DBCM, University of Lausanne, Lausanne, Switzerland, [2]Psychiatric Neuroscience Center, University Hospital of Lausanne, Prilly, Switzerland

Microtubule stability and dynamics are regulated by a variety of proteins. Here, opposite effects on microtubule stability of two proteins found in the growth cone, MAP1B and SCG10, were examined by co-transfection of COS-7 cells and using recombinant proteins in microtubule assembly assays. Microtubule binding was evaluated by electron microscopy. In cells transfected with a 158kDa MAP1B fragment containing the microtubule-binding site, over 80% of the transfected cells maintained intact microtubules upon exposure to 3 µM colcemid. While the microtubule network disappeared in cells transfected with SCG10, a proportion of SCG10 and MAP1B double-transfected cells maintained intact microtubules, suggesting that MAP1B was able to protect microtubules from SCG10 induced dissassembly. However, cells with high expression levels of SCG10 contained little or no microtubules despite the presence of MAP1B. This indicates that SCG10 is more potent to destabilize microtubules than MAP1B to rescue them. In microtubule polymerization assays, MAP1B was able to promote tubulin assembly at a ratio of 1 MAP1B per 70 tubulin dimers and increased resistance of microtubules to the influence of destabilizing drugs. MAP1B also promoted microtubule polymerization at SCG10 concentrations lower than 8 µM. Above 10 µM SCG10, microtubule assembly was blocked independent of the presence of MAP1B. This supports the idea that SCG10 is a tubulin sequestering protein and that MAP1B needs free tubulin dimers to promote assembly. Furthermore, we

found that SCG10 can also bind along the microtubules, both in vitro and in vivo. These studies show that the balance between assembly and disassembly can be shifted by small differences in SCG10 concentration, indicating an important role of a critical balance between MAP1B and SCG10 for the regulation of microtubule dynamics in growth cones.

228

**MAP1B Interacts with Actin and is a Scaffold Protein**

N. Cueille,[1] S. Popa-Nita,[2] G. Dietler,[2] B. M. Riederer[1,3]; [1]DBCM, University of Lausanne, Lausanne, Switzerland, [2]Department of Physics, EPFL, Lausanne, Switzerland, [3]Psychiatric Neuroscience Center, CERY, Prilly, Switzerland

MAP1B is an essential protein during brain development and during neurite outgrowth. Here we have identified by a MAP1B pulldown assay, by 2D gels analysis and by mass spectrometry (MALDI-TOF) its interacting partners. Results were confirmed by Western blots in brain tissue and cell cultures. Furthermore, binding forces were determined by atomic force microscopy. Not surprisingly, major MAP1B associated proteins were tubulin and actin. Both co-precipitated throughout development at similar ratios. MAP1B-actin interaction does not seem to depend on the MAP1B phosphorylation state because actin was also precipitated from brain tissue after exposure to alkaline phosphatase. Especially in newborn tissue, another precipitatated protein of high stoichiometry was glyceraldehyde-3-phosphate dehydrogenase. At lower stoichiometry, a variety of proteins were identified such as heat shock protein 8, dihydropyrimidinase related protein 2, protein-L- isoaspartate O-methyltransferase, ß-spectrin, clathrin protein MKIAA0034 and g-actin. Such proteins seem associated to MAP1B either directly or indirectly via actin, tubulin or GPDH. Differences in association vary, depending on the development state or on the cell type used in the pulldown assay. Interacting forces between MAP1B itself and actin or tubulin were measured by atomic force microscopy and were between 100-180pN. Given the large number of proteins apparently associated with MAP1B, one can conclude that MAP1B has not only a microtubule-stabilization effect, but must act as an actin anchor and may play a role as a scaffold protein for a variety of proteins, this especially at the tip of growth cones or towards the cortical actin cytoskeleton. This work was supported by FNRS grant 3100-067201.01.

**Comparisons of Microtubule Binding Behavior for Several MAPs**

A. D. Stephens, D. S. Razafsky, S. J. King; School of Biological Sciences, University of Missouri-Kansas City, Kansas City, MO

We are interested in characterizing how different microtubule-associated proteins (MAPs) bind to microtubules. We have analyzed MAP binding domains using a novel single-particle binding assay. In the assay proteins were bound to polystyrene beads, the beads were added to a flow cell that had microtubules attached to the surface, and bead movements were recorded with a microscope as the protein bound to microtubules. Various particle tracking software were utilized to analyze bead movement. Mean-squared displacement (MSD) analysis was also used to quantify and classify different binding events by tracking a bead's displacement over time. Tau-coated beads bound to microtubules at a single spot and the beads exhibited short-range diffusion in a circular area from a fixed tether position. The CAP-Gly domain of p150 and the GMAD domain of Gas11 bound similar to Tau except for an increase in the length of the tether between the bead and microtubule. For the basic microtubule binding domain of p150 some beads behaved similar to that seen by the p150 CAP-Gly domain but in other beads the point at which the protein tether contacted the microtubule moved along the microtubule instead of being fixed. The p150 basic domain was the only microtubule binding domain that exhibited this "skating" behavior. The MSD analysis of these "skating" events showed an exponential relationship indicative of semi-constant displacement over time even without a motor protein present. The IMAD domain of Gas11 appeared to have an inhibitory effect on the GMAD/microtubule interaction. The IMAD domain caused the GMAD to have a larger and varying mean-squared displacement. Other MAPs will be analyzed to determine if they fall into one of the classes we observed or if they belong to one or more new classes of microtubule binding behavior.

**Role of MAP200, a Member of Plant XMAP215/Dis1 Family, in Tubulin Polymerization**

T. Hamada,[1] H. Igarashi,[2] T. J. Itoh,[3] T. Shimmen,[1] S. Sonobe[1]; [1]Department of Life Science, University of Hyogo, Hyogo, Japan, [2]Plant Science Center, Riken, Yokohama, Japan, [3]Division of Biological Sciences, Nagoya University, Nagoya, Japan

In plant cell, microtubules (MTs) organize various structures, such as cortical MT, preprophase band, spindle and phragmoplast. Microtubule-associated proteins (MAPs) play important roles in constructing and regulating these MT structures. Therefore the analysis of MAPs is needed in order to understand the function and regulation of MTs in plant cells. We succeeded in purifying a 200 kDa MAP (MAP200) from tobacco BY-2 cells using miniprotoplasts (evacuolated protoplasts), and have analyzed their function in tubulin polymerization. Analysis of the partial amino acid sequence showed that MAP200 was identical to the XMAP215/MOR1 family. Turbidity measurements of tubulin solution suggested that MAP200 promoted tubulin polymerization, and analysis by dark-field microscopy revealed that MAP200 increased both the number and length of MTs, suggesting that MAP200 has an ability to promote MT elongation and nucleation. To elucidate the mechanism of promotion of tubulin polymerization by MAP200, we performed turbidity measurement in the presence of GDP. It is known that the extent of tubulin polymerization is reduced depending on the concentration of GDP. In fact small amount of GDP in the assay sample significantly reduced the extent of tubulin polymerization. In the presence of MAP200, however, small amount of GDP have no apparent effect on the extent of tubulin polymerization. Both electron microscopy and experiments using a chemical crosslinker demonstrated that MAP200 forms a complex with several GTP-tubulin dimers. Surprisingly, the formation of complex between MAP200 and GDP-tubulin dimers was also found. We conclude that MAP200 could promote tubulin polymerization even in the presence of GDP. The analysis of MAP200-GDP-tubulin complex may provide a clue to understand the function of MAP200 in tubulin polymerization.

**Light Chain 3 (LC3) of Microtubule Associated Protein (MAP) 1A and 1B in Smooth Muscle Cell and Cardiomyocyte Differentiation**

N. S. Deshpande, G. M. Cann, M. Rabinovitch; Pediatrics, Stanford University School of Medicine, Stanford, CA

LC3, a marker of autophagy also binds fibronectin mRNA, increases the efficiency of its translation and as a consequence promotes smooth muscle cell (SMC) migration, necessary in the formation of a neointima in the developing ductus arteriosus and in diseased vessels. In the murine embryo,

expression of LC3mRNA is observed in limbs, lungs and brain, and is prominent at sites of neural crest cell differentiation, e.g., cardiac outflow, dorsal root ganglia and commissural neurons. We therefore hypothesized that LC3 might regulate differentiation of smooth muscle, cardiac and neuronal cells. Using embryonal carcinoma (P19) stem cells, we showed increased LC3 following differentiation to SMC but not cardiomyocytes. We also observed an increase in LC3 when neural crest (MONC-1) cells differentiated into SMC. However, overexpression of LC3 in P19 cells was not sufficient to induce SMC differentiation. To determine whether LC3 was necessary for differentiation, we stably transfected P19 cells with LC3 RNAi achieving a 70% knockdown, but differentiation to SMC, neuronal cells and cardiac myocytes was unimpeded. Despite reduced LC3 expression, differentiated cells exhibited characteristic markers, e.g., alpha SM actin, calponin, SM 22, SM-myosin heavy chain (MHC) in SMC;, desmin in cardiomyocytes; and, neurofilament and N-CAM in neuronal cells. Embryonic stem (ES) cells with deletion of both LC3 alleles also differentiated into SMC but not into cardiomyocytes in that no beating cells and no immunoreactivity for cardiac Troponin T, or slow MHC were seen. The absolute requirement for basal levels of LC3 in cardiomyocyte differentiation in embryoid bodies may be related to its requirement in translating a key regulatory protein.

**HDAC6 and Microtubules are Required for Autophagic Degradation of Aggregated Huntingtin**

A. Iwata,[1,2] B. E. Riley,[2] R. R. Kopito[2]; [1]Neurology, Graduate School of Medicine University of Tokyo, Tokyo, Japan, [2]Bio-X, Stanford University, Stanford, CA

CNS neurons are endowed with the ability to recover from cytotoxic insults associated with the accumulation of proteinaceous polyglutamine aggregates via a process that appears to involve capture and degradation of aggregates by autophagy. The ubiquitin-proteasome system protects cells against proteotoxicity by degrading soluble monomeric misfolded aggregation-prone proteins, but is ineffective against, and impaired by non-native protein oligomers. Here we show that autophagy is induced in response to impaired ubiquitin proteasome system activity. We show that ATG proteins, molecular determinants of autophagic vacuole formation, and lysosomes are recruited to pericentriolar cytoplasmic inclusion bodies by a process requiring an intact microtubule cytoskeleton and the cytoplasmic deacetylase HDAC6. These data suggest that HDAC6- dependent retrograde transport on microtubules is used by cells to increase the efficiency and selectivity of autophagic degradation.

**Functional Characterization of DdLIS1 and DdDCX, two Microtubule-associated Proteins involved in Lissencephaly**

I. Schulz, J. Faix, T. Ho, M. Rehberg, R. Gräf; A.B.I. Cell Biology, University of Munich, München, Germany

Lissencephaly results from impaired cell migration of neuronal precursors during development of the neocortex. Mutations in the genes encoding LIS1 and doublecortin (DCX) are responsible for approximately 80% of all cases of lissencephaly. Since *Dictyostelium* is an outstanding model for studies on cell migration and development, we analyzed the homologues of LIS1 and doublecortin. *Dictyostelium* LIS1 (DdLIS1) is a microtubule (MT) and centrosome-associated protein. Co-precipitation experiments revealed that DdLIS1 interacts with dynein, DdCP224 and the small GTPase Rac1A. Replacement of the DdLIS1 gene by the hypomorphic D327H allele had no strong effects on development but disrupted various dynein-associated functions and altered actin dynamics. Our results show that DdLIS1 is required for maintenance of the MT cytoskeleton, Golgi apparatus and nucleus/centrosome association, and they suggest that LIS1-dependent alterations of actin dynamics could also contribute to defects in neuronal migration in lissencephaly patients. DCX is characterized by two conserved tandem repeats of the DC-domain that are involved in microtubule (MT) binding. Although DCX has only been described in vertebrates where its expression was restricted to migrating, developing neurons, we have found a homologue in Dictyostelium. Its sequence similarity is mainly restricted to the DC-domains. GFP-DdDCX was localized along MTs and at the cell cortex. Endogenous DdDCX was distributed similarly but it was only detectable after 8 h of development. DdDCX null mutants exhibited no phenotype. However, DdDCX null mutants additionally carrying the hypomorphic DdLIS1 allele are defective in formation of streams and aggregates during development, although they show normal chemotaxis along external cAMP signals. Stream formation turned out to be independent of MTs. Taken together, this suggests that DdDCX and DdLIS1 cooperate in cAMP signaling and that both proteins may also be involved in cytoskeleton-independent functions in brain development.

**PDZ Domain of HtrA1 is Required for Intracellular Localization of HtrA1**

J. R. Chien,[1] R. Shridhar,[2] J. Staub,[1] V. Shridhar[1]; [1]Experimental Pathology, Mayo Clinic College of Medicine, Rochester, MN, [2]Radiation Oncology, Wayne State University School of Medicine, Detroit, MI

A candidate tumor suppressor HtrA1 is a PDZ containing serine protease and is a member of trypsin-like protease family of proteins initially described in bacteria to be essential for survival at elevated temperature; hence named High temperature requirement A (HtrA). Human HtrA1 was originally described as a secreted protein although cytoplasmic staining of HtrA1 was also reported. To clarify the subcellular localization of HtrA1, we performed subcellular fractionation and immunofluorescence staining. Interestingly, HtrA1 is detected both in membrane and cytosolic fractions. The membrane fractions contains 50 kD full-length HtrA1 whereas cytosolic fractions contain a unique 35 kD isoform as well as the 50 kD full-length HtrA1. Immunofluorescence staining with affinity-purified antibodies against HtrA1 confirms the cytoplasmic staining of HtrA1 co-localizing with microtubules. Localization of deletion mutant HtrA1 constructs indicates that PDZ domain is required for cytosolic localization. Whereas GFP-tagged full-length HtrA1 localizes to both endoplasmic reticulum and microtubules, GFP-tagged PDZ-deleted HtrA1 localizes exclusively to endoplasmic reticulum. In addition, co-culture of HtrA1 expressing cells with HtrA1-null cells led to cytosolic localization of HtrA1 in the null cell lines. Transient expression of HtrA1 in the null cell lines produces clusters of HtrA1-positive cells indicating the capacity of HtrA1 to transduce into neighboring cells. These evidences suggest that HtrA1 may contain the protein transduction domain. Consistent with this observation, HtrA1 contains a region rich in lysine and arginine in PDZ domain. These results point to the role of PDZ domain in protein transduction and the intracellular localization of HtrA1.

**Ase1p Stabilizes the Number and Distribution of Antiparallel Microtubules at the Spindle Midzone**

I. Loiodice, J. Czupryna, P. T. Tran; Cell and Developmental Biology, University of Pennsylvania, Philadelphia, PA

Fission yeast ase1p belongs to the conserved ASE1/PRC1/MAP65 family of microtubule bundling proteins, which function to organize antiparallel midzone microtubules during mitosis, thus lending structural integrity to the bipolar spindle. Mitosis of fission yeast occurs in three phases: I) spindle formation, where the spindle is initially organized and reached length of ~3 um; II) metaphase and anaphase A, where the spindle remains at ~ 3 um long; and III) anaphase B, where the spindle quickly elongates to the final length of ~ 14 um. Live cell imaging showed that ase1p-GFP is recruited to the spindle during phase I, and then localized to the midzone during phase II and III. FRAP showed that ase1p-GFP at the spindle midzone is tightly bound to the microtubules, with the recovery half-time of t1/2 ~ 400 s. Quantitative fluorescence analysis of the mitotic spindles of wild-type cells showed that the spindle microtubules are symmetrically organized by the two spindle pole bodies (SPBs), with each opposite SPB nucleating similar number of microtubules during mitosis. In contrast, in ase1Δ cells the spindle microtubules appeared not symmetrical. There are often no clear midzones of microtubule overlapping regions in the ase1Δ cells. In addition, one SPB often nucleate more microtubules than its sister SPB. Without properly organized spindles and spindle midzones, ase1Δ cells exhibited a delay in phase II, and often showed premature spindle breakage during phase III. We propose that ase1p, by stabilizing antiparallel microtubules at the spindle midzone in a symmetrical manner, is in a pathway which regulate the number of SPB-nucleated microtubules.

### Binding Sites of Tau Repeat Motifs on Microtubules

A. Mitra,[1] D. Sept[2]; [1]Chemical Engineering, Washington University, St. Louis, MO, [2]Biomedical Engineering and Center for Computational Biology, Washington University, St. Louis, MO

Microtubule associated proteins, like tau, influence dynamic instability by stabilizing microtubules. Various isoforms of tau include a three to four 18-residue microtubule binding repeat separated by 13-14 residue inter-repeat. Experimental evidence for the structure of microtubule-bound tau has been unequivocal. With preassembled, taxol-stabilized microtubules decorated with tau, cryo-EM shows evidence for longitudinal binding of tau along individual protofilaments (Al-Bassam et. al, 2002), while atomic force microscopy at low tau to tubulin molar ratio indicates that tau oligomers form ring structures that encircle microtubules (Makrides et. al, 2003). In contrast, cryo-EM studies of microtubules copolymerized with tau in absence of taxol, suggest that tau and taxol binding sites overlap (Kar et. al, 2003). Employing stopped-flow kinetics and equilibrium competition binding experiments, two separate sites for tau binding has been proposed, namely, reversible binding of tau as seen with taxol-stabilized, preassembled microtubules, and secondly, nonexchangeable binding of tau under conditions of copolymerization of tau and tubulin (Makrides et. al, 2004). Recently, using metal shadowing and cryo-EM, tau has been identified to bind solely to the outside of microtubules both laterally and longitudinally (Santarella, 2004). None of these studies address the atomistic details of the interactions between the tau repeats and microtubules. In this study, using molecular dynamic simulations and molecular docking, we identified that the SKIGSTENLKHQ fragment of repeat motif R1 binds to beta-tubulin at the intra-dimer interface, as does the corresponding 12-residue fragment of repeat R4, consistent with ClustalW sequence alignment that R1 has higher homology to motif R1 than to other repeats. The corresponding fragments of repeat motifs R2 and R3 bind to alpha-tubulin near helix H12 and C-terminus of beta-tubulin. Our model supports longitudinal and lateral binding of tau to microtubules.

### Molecular Mechanisms of the Interaction between Tubulin and the Proteins of the Stathmin Family

I. Jourdain, M. J. Clement, S. Lachkar, B. Gigant, M. Knossow, A. Sobel, P. A. Curmi; IMBS, Palmerston North, New Zealand

Stathmin is a small cytosolic phosphoprotein which regulates microtubule dynamics by sequestering the microtubule subunit protein tubulin, thus preventing its incorporation into microtubules. The so-formed T2S complex is made of two ab tubulin heterodimers per stathmin molecule. Stathmin is the generic element of a protein family which includes RB3 that shares a highly conserved stathmin-like domain (SLD). Like stathmin, all SLDs are able to limit tubulin polymerization via the formation of T2S complexes, although the various complexes display different kinetics. The present work is aimed at understanding the mechanisms that lead to the SLD-specific interaction with tubulin. We dissected the role of three regions of the SLD by the means of recombinant fragments and chimeras of stathmin and RB3SLD. Physical biochemistry techniques allowed us to highlight that tubulin interacts co-operatively with stathmin. We also determined that the N-terminus and second tubulin-binding site regions make each SLD unique regarding tubulin binding. In parallel, X-ray crystallography and NMR data showed that the N-terminal region of SLDs forms a b-hairpin that caps the a-tubulin subunit in a region that mediates longitudinal tubulin-tubulin contacts. Together, this work has lead to the design of peptides from SLDs capable of mimicking the effect of the full-length SLDs on microtubule polymerization in vitro. Such peptides may contribute to the development of molecules that could slow down the cell cycle and be useful for the treatment of cancer.

### Actin Assembly, Contraction, and Adhesion during Spontaneous Polarization of Crawling Cells: Which of the Three Comes First?

S. Bohnet, S. Schaub, J. Meister, A. B. Verkhovsky; Lab of Cell Biophysics, Ecole Polytechnique Fédérale de Lausanne, Lausanne, Switzerland

Cell polarization and directional locomotion are believed to involve asymmetry in actin assembly, contractility, and substrate adhesion. These asymmetries could develop in response to extracellular directional stimuli or as a result of spontaneous break of symmetry. We investigated random polarization in a model system of fish epidermal keratocytes. The cells were rendered isotropic and then induced to polarize by respectively depleting and restoring bivalent cations in culture media. We analyzed the distribution and dynamics of actin and myosin II using fluorescence speckling, conventional fluorescence microscopy and computer tracking, and studied the dynamics of substrate adhesions with interference reflection microscopy. The cells initially exhibited uniform actin assembly and retrograde flow of actin network in the lamellipodia all around the cell perimeter. Upon polarization, retrograde flow accelerated at the prospective rear of the cell, but actin assembly persisted at the rear at levels comparable with the assembly at the front long after the cell started to migrate directionally. In contrast to the smooth lamellipodia at the cell front, the lamellipodia at the rear developed filopodia-like ridges, which persisted as retraction fibers when the rear lamellipodia eventually retracted. We did not detect major differences in the density of myosin II at the prospective front and rear of the cell, but observed local areas of detachment from the substrate at the prospective rear. The results suggest that initial polarization results from asymmetry in actin retrograde flow, which is likely caused by detachment from the substrate in limited areas of the cell (focal detachments). **Filament Packing Dynamics Generate Protrusive Force in Amoeboid Cell Motility**

L. Miao,[1] O. Vanderlinde,[1] J. Liu,[2] R. Grant,[3] A. Wouterse,[4] A. Philipse,[4] M. Stewart,[3] T. M. Roberts[1]; [1]Department of Biological Science, Florida State University, Tallahassee, FL, [2]Institute of Molecular Biophysics, Florida State University, Tallahassee, FL, [3]MRC Laboratory of Molecular Biology, Cambridge, United Kingdom, [4]Van't Hoff Laboratory for Physical and Colloid Chemistry, Debye Institute, University of Utrecht, Utrecht, The Netherlands

Localized cytoskeletal assembly powers the leading edge protrusion in amoeboid cells but the mechanism by which this process pushes the membrane remains controversial. Amoeboid sperm of the nematode *Ascaris suum* extend a lamellipod that produces locomotion like that seen in conventional crawling cells, but the sperm movement is based on MSP filaments instead of actin. The MSP motility apparatus has been reconstituted in vitro; vesicles derived from plasma membrane trigger the assembly of MSP fibers to push the vesicle forward as they elongate. Every growing fiber exhibited a crescent-shaped region just behind the vesicle where the optical density was greater than elsewhere in the fiber. This dark crescent moved forward in concert with the vesicle as the fiber elongated and was located at the site where the force for vesicle movement is generated. We used electron tomography to show that the position of the dark crescent corresponded to the region where the filaments were more tightly packed. The packing of MSP filaments, which are relatively straight and have a persistence length of 9 µm, resembles that seen with rigid rods. The packing density of rods is inversely proportional to their aspect ratio, so longer rods pack less densely than shorter rods, suggesting that as filaments elongate their packing density decreases thereby generating a gel expansion that produces protrusive force. Consistent with this hypothesis, an engineered MSP mutant that generates shorter filaments results in higher filament packing density and slower movement. We propose that filament packing dynamics contribute generally to protrusive force generation in amoeboid cell motility. Supported by NIH grant GM29994.

**Active Bleb Formation Is Abated in *Lytichinus variagatus* Red Spherule Coelomocytes Upon Disruption of Acto-Myosin Contractility**

A. K. Sturycz, L. Winslow; Biology, Northwestern College, St. Paul, MN

Red spherule coelomocytes are one of five known immune cells in the sea urchin *Lytichinus variagatus*. These cells have a complex physiology and morphology, and have been previously characterized as motile $O_2$ transport cells (L.D. Winslow et al., MBC 14:128, 2003). Real time and time-laspse video microscopy of red spherule cells reveal a unique and dymanic array of cellular shapes and movements. Cells were observed to continuously send out large membrane extensions or blebs followed by extensive cytoplasmic streaming of cellular organelles and red pigmented granules which contain the the bacteriocide, echinochrome and the oxygen-binding protein hemoglobin. These cellular projections are not limited to movement along a substrate but occur in three dimensions. Western blot studies indicate that there is an abundance of cellular actin, myosin and tubulin within the cells. We have further examined the complex shape and motility by using a series of cytoskeletal disruption drugs. Treatment with 30µM cytochalasin B revealed a rapid and reversible change in both shape and motility. Cells appeared rounded having either a single spherical cell body with elongated membrane extensions or multiple spheres attached by short membrane extensions. Blebbing, intracellular organelle and granule motility appeared to cease. This attenuation of motility and blebbing was restored by washing out cytochalasin B. Treatment with phalloidin revealed a similar attenuation of motility. Treatment with 100µM blebbistatin showed complete and irreversible retraction of blebs and attenuation of all intracellular motility. Disruption of the microtubules using either nocodazole or taxol, showed no effect on cellular shape and motility. These results indicate that the acto-mysoin contractile mechanism is responsible for the dynamics of cell shape and membrane blebbing in invertebrate immune cells.

**Resveratrol Signals to the Actin Cytoskeleton to Promote Global Filopodia Extension and Inhibit Cell Migration**

N. G. Azios,[1,2] M. Harris,[1] L. Krishnamoorthy,[1] L. A. Cubano,[3] S. F. Dharmawardhane[1,2]; [1]Molecular Cell and Developmental Biology, University of Texas at Austin, Austin, TX, [2]Anatomy and Cell Biology, Universidad Central del Caribe, Bayamon, PR, [3]Anatomy and Cell Biology, Universidad Central del Caribe, Bayamon, PR

Resveratrol, a phytoestrogen in red wine, binds estrogen receptors α and β to exert both estrogenic and antiestrogenic effects. Our previous results show that while estrogen (E2) extends lamellipodia and promotes cell migration, resveratrol acts opposite by inducing filopodia and inhibiting cell migration. We hypothesize that the inhibitory action of resveratrol on cell migration may depend on its induction of sustained and global filopodia. The objective of this study is to delineate the mode of resveratrol signaling to the actin cytoskeleton. Therefore, we evaluated the role of Rho GTPases Rac and Cdc42 on resveratrol-induced filopodia extension. MDA-MB-231 cells stably expressing dominant negative Rac1(T17N) or Cdc42(T17N) were created and the effect of resveratrol on the actin cytoskeleton was analyzed. The ability of resveratrol to activate Rac1 or Cdc42 was monitored by pulling-down the active Rac1 or Cdc42 using a GST-PBD fusion protein. Stable expression of Rac1(T17N) did not affect resveratrol-induced filopodia extension, though resveratrol (5 µM) did induce Rac activity at 5-30 minutes. E2 did not induce lamellipodia in cells expressing Rac1(T17N) indicating that E2 signals via Rac to promote cell migration. Resveratrol (5 µM) was partially effective in filopodia extension in cells stably expressing Cdc42(T17N), but did not affect Cdc42 activity at 5-30 minutes. These data indicate novel Rac1- and Cdc42-dependent and independent signaling pathways for resveratrol-mediated modulation of the actin cytoskeleton leading to persistent filopodia extension and decreased cell migration. Since cell migration is a prerequisite for metastasis, resveratrol may act as a novel chemopreventive for metastatic breast cancer.

242

**A Role for ß4 Integrin in Directional Migration**

C. E. Pullar,[1] M. P. Marinkovich,[2] R. R. Isseroff[1]; [1]Dermatology, University of California, Davis School of Medicine, Davis, CA, [2]Program in Epithelial Biology, Stanford University School of Medicine, Stanford, CA

Wounding immediately generates an electric field (EF) that could be the earliest signal keratinocytes sense to initiate directional migration and re-

epithelialization. Indeed, keratinocytes migrate directionally towards the cathode (wound center) in an applied EF, a process termed galvanotaxis. While we have established a role for the epidermal growth factor receptor (EGFR) in galvanotaxis, the role of integrins is unknown. As a6ß4 integrin plays a role in keratinocyte chemotaxis and its ligand, laminin 5, is present at wound edges, does it play a role in keratinocyte galvanotaxis?. Immortalized ß4 negative keratinocytes were retrovirally transduced with a vector control (ß4-) or the ß4 gene (ß4+). Cells were starved of growth factors overnight and experiments were performed in the presence or absence of EGF (2ng/ml). Loss of ß4 has no effect on cell motility, while EGF increases it by 40%. However, ß4- cells are blinded to the EF and migrate randomly, while addition of EGF or re-expression of ß4 partially restores directional migration. This suggests a possible synergistic co-operation between EGF and ß4 integrin-mediated signals to initiate galvanotaxis. Loss of a 6ß4 ligation by laminin 5, either by transducing an adhesion-defective ß4 gene or addition of an anti- a 6ß4 antibody (ASC-8), increases motility in the presence of EGF while blinding the cells to the EF. Once more, the addition of EGF partially restores directional migration. Galvanotaxis requires formation of a new leading edge facing the cathode. Leading edge protrusion and adhesion is regulated by rac in many systems. Indeed, transduction of a constitutively active rac mutant into the adhesion-defective ß4+ cells fully restores galvanotaxis in the presence of EGF. It appears that keratinocyte EF-mediated directional migration, galvanotaxis, requires an EGF-mediated signal together with the ß4 integrin-mediated activation of rac.

243

**Characterization of Arf6 and FIP3 Interactions and their Role in Regulating Actin Dynamics at The Leading Edge of Migrating Cells**

E. Schonteich,[1] G. Simon,[1] H. T. Matern,[2] M. Pilli,[3] J. R. Junutula,[3] R. Prekeris[1]; [1]Cellular and Developmental Biology, UCHSC, Aurora, CO, [2]Exelixis, South San Francisco, CA, [3]Genentech, South San Francisco, CA

Emerging evidence has identified Arf6 as a key regulator of cytoskeletal remodeling and targeting membrane traffic during the transition of epithelial cells from polarized to a highly motile phenotype. While the role of Arf6 in regulating cytoskeleton is well established, little is known about the mechanism of Arf6 regulation during cell motility. Recently we have identified FIP3 as an Arf6 binding protein that may be involved in regulating Arf6 function (Fielding et al, 2005). What makes this discovery especially exciting is that FIP3 is also a Rab11-binding protein. Interestingly, Rab11 is known for its function in regulating endocytic membrane recycling to plasma membrane. Thus, it is tempting to speculate that FIP3 may play an integrative role between Arf6 and Rab11 by coupling Arf6-dependent cytoskeleton remodeling to Rab11-dependent targeted membrane transport to the leading edge of migrating cell. In this study we further characterize FIP3 and Arf6 interaction. We map FIP3-binding domain within Arf6 and use surface plasmon resonance to measure the affinities of FIP3 and Arf6 as well as FIP3 and Rab11 binding. Furthermore, we show that calcium binding to EF-hands regulates FIP3 conformation in vitro and its interaction with Arf6 in vivo. Finally, we show that FIP3 mediates the motility of MDA-MB-231 breast cancer cells by regulating Arf6 activation and actin stability at the leading edge.

244

**EphB/ephrin-B Interactions are Involved in Attachment and Spreading of Adult Human Dental Pulp Stem Cells**

A. Stokowski,[1,2,3] S. Gronthos, [3] S. Shi,[4] S. A. Koblar[2,1]; [1]School of Molecular and Biomedical Science, University of Adelaide, Adelaide, Australia, [2]ARC Special Research Centre for the Molecular Genetics of Development, Adelaide, Australia, [3]Division of Haematology, Institute of Medical and Veterinary Science, Adelaide, Australia, [4]Craniofacial & Skeletal Diseases Branch, National Institute of Dental & Craniofacial Research, National Institute of Health, Bethesda, MD

The inner chamber of the tooth, the dental pulp, is comprised of soft connective tissue derived from migrating neural crest cells during development. Dental pulp stem cells (DPSC) were isolated from the pulp of human adult third molar teeth. DPSC are capable of giving rise to pulp fibroblasts, odontoblasts, perivascular cells, adipocytes and preliminary evidence also suggests neural-like cells. The Eph family of receptor tyrosine kinases and their ligands, the ephrin molecules, play an essential role in the migration of neural crest cells during development. The present study examined the expression pattern and function of EphB/ephrin-B molecules on DPSC. Multiple receptors and ligands were identified on DPSC by real time PCR and immunohistochemistry. The function of EphB/ephrin-B molecules during DPSC attachment and spreading was assessed in the presence of Eph/ephrin-Fc fusion proteins using an established *in vitro* cell-spreading assay. In response to either EphB2-Fc or ephrin-B1-Fc, DPSC formed rounder and smaller cell bodies demonstrated by F-actin distribution, and restricted their ability to spread as indicated by time-lapse imaging. Additionally, immature focal adhesions were identified at the edge of the cell membrane, reminiscent of spreading initiation centers (SIC), which have only been observed at early stages of cell spreading. Inhibitor assay analysis indicated Eph forward signaling through the mitogen activated protein kinase (MAPK) pathway restricted DPSC spreading, while reverse signaling through the ephrin ligand was mediated via the phosphorylation of Src family tyrosine kinases, activating downstream signaling cascade. Collectively, these studies indicated that EphB/ephrin-B molecules provide an inhibitory environment for DPSC attachment, consequently resulting in the lack of spreading and detachment. These results may have implications for dental pulp development and regeneration.

**Ena/VASP Proteins Modulate the Shape of the Lamellipodial Leading Edge in Fish Keratocytes**

C. I. Lacayo, J. A. Theriot; Biochemistry, Stanford University, Stanford, CA

Ena/VASP proteins have been shown to play critical roles in actin dynamics and cell migration in several cell types including fibroblasts and *Dictyostelium discoideum*, where they influence cell speed and persistence. We are studying Ena/VASP proteins in the shape and migration of *Hypsophrys nicaraguensis* (Nicaraguan cichlid) epithelial keratocytes, which are among the fastest locomoting eukaryotic cells. Using polyclonal antibodies and GFP-tagged constructs, we have localized Ena/VASP proteins to focal adhesions in keratocytes found in epithelial sheets and to the leading edge of lamellipodia in polarized migratory keratocytes. Interestingly, VASP only appears to strongly localize to the “smooth” and not “rough” leading edge of lamellipodia. We have also found that keratocytes with strong localization of VASP at the “smooth” edge of lamellipodia have a distinct F-actin distribution compared to those keratocytes with “rough” lamellipodial edges. Additionally, treatment of cells with low levels of cytochalasin D delocalized VASP from lamellipodial edges and changed the F-actin distribution in the lamellipodia to more closely resemble the “rough” edge phenotype. We are currently examining how lamellipodial edge shape is affected by the delocalization of Ena/VASP proteins by competition with capping protein. We also examined the effect of mislocalizing Ena/VASP proteins in the motile behavior of keratocytes by using an Ena/VASP-sequestering construct targeted to mitochondria. We found that the mean speed, speed persistence, and trajectories of fish

keratocytes expressing the Ena/VASP-sequestering construct are not different compared to keratocytes expressing control constructs. Our results show that Ena/VASP proteins do not play an important role in determining the motile behavior of migrating keratocytes. However, Ena/VASP proteins are associated with the actin remodeling machinery that establishes the shape of the lamellipodial leading edge in crawling cells.

**Correlated Molecular Motions of Actin Cytoskeleton and Focal Adhesion Molecules within Adhesion Complexes**

K. Hu, L. Ji, G. Danuser, C. Waterman-Storer; Dept. of Cell Biology, Scripps Research Institute, La Jolla, CA

During cell migration, forces generated within the actin cytoskeleton by myosin contraction and actin polymerization at the cell front induce actin retrograde flow within the leading lamella. To investigate how the kinematics of the actin cytoskeleton are transduced to the ECM through Focal Adhesion complexes (FA), we imaged and correlated the kinematics of actin cytoskeleton with GFP-conjugated focal adhesion molecules in living cell using quantitative multispectral Total Internal Reflection Fluorescent Speckle Microscopy (TIR-FSM). The GFP- FA molecules fall in three categories based on the levels of organization within the FA, 1) actin binding proteins (alpha-actinin, talin, vinculin), 2) ECM binding proteins (αV/β3 integrins), and 3) "FA core" proteins, which do not directly interact with either actin cytoskeleton or ECM ( paxillin, zyxin and Focal adhesion kinase). To quantitatively describe the coupling between FA protein and the actin cytoskeleton, we first generate flow fields of actin and GFP-FA speckles by cross-correlating molecular motion in time, then calculate direction and speed correlation of the flow fields. Our results clearly show that FA components do not act concertedly as one unit, each displaying distinct kinematic behaviors. In particular, the actin binding FA components alpha-actinin, vinculin clearly have speckle motions that are highly correlated to actin motion indicating kinematic coupling between these molecules within FA. Other FA molecules examined display significantly lower level of coupling. Upon over-expression of constitutively active RacQ61L, we detect different degrees of increase in the coupling between actin and actin-binding FA molecules as well as FA core molecules, with the most pronounced effect on vinculin and talin motion within FA. FA actin binding proteins thus provide important regulatable linkages between actin and ECM.

**Kinetic Analysis of the Coupling between Temporal Production of Secondary Messengers and Pseudopod Projection in Cells Activated with Chemoattractant**

D. V. Zhelev, L. Vankova; Mechanical Engineering and Materials Science, Duke University, Durham, NC

Chemoattractants activate G protein coupled receptors (GPCRs) and induce cytoskeleton remodeling and chemotaxis. We have sown that the rate of pseudopod extension is dependent on ligand concentration (Chodniewicz and Zhelev, 2003, Blood 101:1181). We have also shown that the rate of pseudopod extension is dependent on the activity of kinases involved in the early stages of activation (Chodniewicz, Alteraifi and Zhelev, 2004, J. Bol. Chem. 279: 24460). This suggests that GPCRs are continuously managing the cytoskeleton remodeling. Here we explore the coupling between the production of secondary messengers and pseudopod projection. The temporal production of the secondary messenger PtdIns(3,4,5)$P_3$ is monitored by measuring the membrane translocation of PH-Akt-GFP or by measuring the phosphorylation of Akt/PKB in HL-60 cells. A kinetic model for PtdIns(3,4,5)$P_3$ production and Akt/PKB phosphorylation is developed in order to establish a temporal scale for comparison of the observed events. The model predicts that the apparent rate of production of secondary messengers during initial activation should be proportional to the apparent rate of increase of receptor occupancy or to ligand concentration. This is tested by measuring the rate of initial Akt/PKB phosphorylation in cells activated with either fMLP or SDF-1. Neutrophils express two receptors for fMLP: FPR1 is a high affinity receptor and FPR2 is a low affinity receptor, while SDF-1 is recognized by only one receptor CXCR4. The experimental data confirm that initial Akt/PKB phosphorylation is dependent on receptor occupancy and were capable of distinguishing between the dual receptor and single receptor activations. The dependence of the rate of initial pseudopod extension on ligand concentration was the same as the same dependence fpr Akt/PKB phosphorylation, however pseudopod extension was delayed by 20 to 30 s.

**Periodic Remodeling of the Actin Cortex Occurs in Two Mechanically Distinct Modes During Amoeboid Movement**

T. Soldati,[1] K. Yoshida[2]; [1]Biochemistry Department, University of Geneva, Geneva, Switzerland, [2]Department of Biological Sciences, Imperial College London, London, United Kingdom

It is widely believed that cell motility is caused by actin polymerisation directly pushing against the membrane at the leading edge producing filopodia and lamellipodia. Alternatively, cortical F-actin can counteract the cytoplasmic pressure generated by the contractile activity of myosin II at the posterior end. The latter has been revealed by studies of blebs, spherical hyaline protrusions that occur in stress or pathological situations when membrane detaches from its supporting cortex. The contribution of blebs to physiological cell motility has not been well appreciated. Using highg-resolution imaging, we found that Dictyostelium cells moving in a physiological but hypo-osmotic milieu are continuously blebbing. We quantitated cell motility and found that pseudopod extension, cell body retraction, and centroid movement were all decreased by an increase of osmolarity of the milieu in wild-type cells but not in myosin-II null cells. These observations suggested two mechanically different protrusive processes, characterised by blebs and filopodia, respectively. The bleb-mode becomes dominant when cells move at high speed under hypo-osmotic conditions, whereas the filopodium-mode becomes dominant when cells move at moderate speed under hyper-osmotic conditions, or when myosin II is defective. Spectral analysis, however, showed that cell movement has peaks at a fundamental frequency of 0.2 Hz and its harmonics, and that the power spectra of movement of blebbing cells are indistinguishable from those of non-blebbing filopodia-rich cells. In addition, cells in blebbing-mode chemotaxed as efficiently as cells in filopodium-mode, suggesting that the direction of blebbing is under the control of cAMP signalling in a way similar to filopodia extension. We therefore conclude that both bleb- and filopodia-modes occur through remodeling of the actin cortex driven by the same machinery but make use of different forces, fluid pressure and actin polymerisation, respectively.

**A WAVE2/Abi1 Complex Mediates CSF-1-induced F-actin Rich Membrane Protrusions and Migration in Macrophages**

W. G. Abou Kheir, J. Gevrey, H. Yamaguchi, B. M. Isaac, D. Cox; Anatomy and Structural Biology, Albert Einstein College of Medicine, Bronx, NY

Colony-stimulating factor 1 (CSF-1) is an important physiological chemoattractant for macrophages. The mechanisms by which CSF-1 elicits the formation of filamentous actin (F-actin) rich membrane protrusions and induces macrophage migration are not fully understood. In particular, very little is known regarding the contribution of the different members of the Wiskott-Aldrich Syndrome protein (WASP) family of actin regulators in response to CSF-1. Although a role for WASP itself in macrophage chemotaxis has been previously identified, no data was available regarding the function of WASP family verprolin-homologous (WAVE) proteins in this cell type. We found that WAVE2 was the predominant isoform to be expressed in primary macrophages and in cells derived from the murine monocyte/macrophage RAW264.7 cell line (RAW/LR5). CSF-1 treatment of macrophages resulted in WAVE2 accumulation in F-actin rich protrusions induced by CSF-1. Inhibition of WAVE2 function by expressing a dominant-negative mutant in RAW/LR5 cells or introducing anti-WAVE2 antibodies in primary macrophages and RAW/LR5 cells as well as reduction of endogenous WAVE2 expression by RNA-mediated interference (RNAi) in RAW/LR5 cells resulted in a significant reduction of CSF-1-elicited F-actin protrusions. WAVE2 was found in a protein complex together with Abelson kinase interactor 1 (Abi1) in resting or stimulated cells. Both WAVE2 and Abi1 were recruited to and necessary for the formation of F-actin protrusions in response to CSF-1. Reducing the levels of WAVE2, directly or by targeting Abi1, resulted in an impaired cell migration to CSF-1. Altogether these data identify a WAVE2/Abi1 complex crucial for the normal actin cytoskeleton reorganization and migration of macrophages in response to CSF-1.

**Dynamic Relationships Among PI 3-kinase Signaling, Cell Spreading, and Asymmetric Membrane Protrusion Following the Attachment of Fibroblasts to Surfaces**

M. Weiger, J. Haugh; Chemical and Biomolecular Engineering, North Carolina State University, Raleigh, NC

Cell adhesion and migration are essential steps in numerous biological processes such as wound healing. Cell spreading and migration involve both surface attachment and cytoskeletal reorganization, leading to membrane extension and ultimately cell polarization, processes which are stimulated and coordinated through intracellular signal transduction pathways mediated by adhesion and chemoattractant receptors. In fibroblasts and many other cell contexts, activation of the phosphoinositide (PI) 3-kinase pathway is strictly required for motility. PI 3-kinases generate specific 3' PI lipid products, which act as membrane second messengers, and the spatial pattern of 3' PI density in the membrane is thought to control the directionality of membrane protrusion and cell migration. As a model system, we have quantitatively followed the time course of PI 3-kinase activation, membrane spreading and post-spreading motility of mouse fibroblasts following their initial attachment to fibronectin and polylysine coated surfaces. Two imaging modes, total internal reflection fluorescence and epifluorescence microscopies, were used in conjunction with fluorescent 3' PI and nonspecific probes to evaluate the relationships among these processes for various plating conditions. We report the following findings: 1) spontaneous PI 3-kinase activation generally foretells the dramatic acceleration of cell spreading rate at localized regions of the contact area; 2) cells plated on fibronectin versus poly-lysine show similar qualitative behavior in this respect but spread at different rates; and 3) after the initial spreading achieves a steady state, cells often exhibit transient oscillations in PI 3-kinase activity that coincide with localized membrane protrusions, which may play an important role in establishing polarity for migration.

**WASP-Interacting Protein (WIPa) is Required for Filopodia Formation and Prompt Chemotactic Response to a New Gradient**

S. A. Myers, J. W. Han, L. Leeper, S. Gruver, C. Y. Chung; Pharmacology, Vanderbilt Univ. Med. Ctr., Nashville, TN

WASP family proteins activate F-actin assembly via stimulation of the Arp2/3 complex and have been shown to be necessary in diverse cellular processes including chemotaxis. In this study, we examined the role of WASP-interacting protein (WIP) in the process of WASP-mediated actin assembly during chemotaxis of *Dictyostelium*. Mutations of the WH1 domain of *Dictyostelium* WASP led to a reduction in binding to a newly identified *Dictyostelium* homolog of mammalian WIP, WIPa, reduced F-actin localization at the leading edge of chemotaxing cells, and led to a reduction in chemotactic efficiency. WIPa translocates to cortical membrane upon uniform cAMP stimulation in a PI3 kinase-dependent manner and to sites of newly forming filopodia as well as the leading edge of chemotaxing cells and WIPa appears to colocalize with WASP at the leading edge of chemotaxing cells, presumably resulting in the stimulation of F-actin assembly as well as filopodia formation. WIPa increases F-actin nucleation and elongation both *in vivo* and *in vitro* in a WASP-dependent manner. WIPa overexpressing cells exhibited higher levels of leading edge F-actin content, defects in chemotactic efficiency, and more filopodia. Reduced expression of WIPa by expressing a hairpin-WIPa (hp-WIPa) construct resulted in hyperpolarized cells and these cells exhibit a small, but significant increase in mean velocity and chemotactic index, indicating that these cells are moving more straightforward to the cAMP source than wild type cells. However, hp-WIPa cells exhibit a delayed response to the new chemoattractant source due to delayed formation of filopodia toward the new gradient. These results suggest that WIPa and WASP allow cells to reorient toward a new gradient promptly by initiating localized bursts of actin polymerization and/or elongation.

252

**Tuba: A Cdc42 GEF that drives NWASP-dependent Actin Assembly**

E. M. Kovacs, F. B. Gertler; Biology, Massachusetts Institute of Technology, Cambridge, MA

Rapid rearrangement of the actin cytoskeleton underlies normal cellular motility. Tuba is a multidomain scaffolding protein that functions to bring together cellular trafficking and signaling pathways with actin regulatory proteins. Tuba has an internal BAR domain, is a GTPase exchange factor (GEF) for Cdc42, and binds directly to NWASP through a C-terminal SH3 domain. Overexpression of Tuba exacerbates dorsal ruffling observed in B16 melanoma cells. Ruffles form and dissipate rapidly and continuously with an apparent random distribution over the entire surface of the cell. Tuba puncta are observed to localize to the base of these short-lived dorsal ruffles coincident with NWASP, Cdc42, Arp2/3 and actin. Treatment of cells with wiskostatin, a specific inhibitor of NWASP, results in dissolution of Tuba puncta and a cessation of ruffling. Additionally, ruffling requires functional BAR, GEF and C-terminal SH3 domains of Tuba, and a dynamic actin cytoskeleton. Ruffling shows no obvious association with endocytosis using TR-Dextran as a fluid phase marker and has no apparent colocalisation with caveolin. Motile cells undergo morphological changes that result in the formation of distinct plasma membrane protrusions such as dorsal ruffles and invadopodia. Tuba is a key component of the molecular machinery driving the formation of these processes.

**Tonic Protein Kinase A Activity Maintains Inactive Beta 2 Integrins in Unstimulated Neutrophils by Reducing Myosin Light Chain Phosphorylation: Role of Myosin Light Chain Kinase and Rho Kinase**

C. D. Chilcoat, Y. Sharief, S. L. Jones; Clinical Sciences, North Carolina State University, Raleigh, NC

Activation of beta 2 integrins is necessary for neutrophil adhesion and full activation of neutrophil effector functions. We demonstrated previously that inhibition of PKA activity in quiescent neutrophils is sufficient to increase beta 2 integrin cell surface expression, affinity, and adhesion. Thus, a tonic level of PKA activity present in unstimulated neutrophils prevents inappropriate activation of beta 2 integrins. Myosin light chain (MLC) phosphorylation is an important regulator of leukocyte integrin function and adhesion. Moreover, PKA regulates MLC phosphorylation via inhibiting myosin light chain kinase (MLCK), and MLC dephosphorylation via effects on the Rho kinase/myosin light chain phosphatase pathway. We hypothesize that the tonic inhibitory effect of PKA upon beta 2 integrin activation neutrophils operates via its inhibition MLC phosphorylation. We demonstrate here that that inhibition of PKA activity with KT5720 activated beta 2 integrins and adhesion coincident with an increase in myosin light chain Ser 19 phosphorylation. KT5720-induced activation of beta 2 integrins, adhesion, and MLC Ser 19 phosphorylation was abolished by pretreatment with MLCK inhibitor ML-7, a specific MLCK inhibitory peptide, and the Rho kinase inhibitor Y-27632. These findings demonstrate that tonic PKA activity prevents activation of beta 2 integrins and adhesion by dampening MLC phosphorylation via a mechanism that operates by inhibiting both MLCK and Rho kinase signaling pathways.

**Mechanics of Neutrophil Phagocytosis**

M. Herant,[1] V. Heinrich,[2] M. Dembo[1]; [1]Biomedical Engineering, Boston University, Boston, MA, [2]Biomedical Engineering, University of California, Davis, CA

A complete picture of phagocytosis requires an understanding of the mechanical events that lead to cellular deformation, protrusion of a phagocytic cup, and eventual formation of a phagosome. We study the mechanics of FcgammaR-driven phagocytosis of antibody-coated polystyrene beads (diameters from 3 um to 11 um) by initially spherical neutrophils, and we present side by side microscopic observations of real neutrophils and results from finite element computer simulations of virtual neutrophils with realistic cytoskeletal, cytosolic and membrane dynamics. These comparisons are used to assess the viability of various mechanistic models for neutrophil phagocytosis with special attention to the time evolution of the cell morphology, of the motion of the bead, and of the cortical tension. We find that the optimal models involve two key mechanical interactions: a repulsion between cytoskeleton and free membrane that drives protrusion, and an attraction between cytoskeleton and membrane newly adherent to the bead that flattens the cell into a thin lamella with retrograde centripetal cytoskeletal flow. Other models based on phenomena such as cytoskeletal expansion or swelling appear to be ruled out as main drivers of phagocytosis because of the characteristics of bead motion during engulfment. The transitions in cell shape observed to take place during phagocytosis can be successfully interpreted via the interplay of interior cytoplasmic viscosity and surface cortical tension. We finally show that the protrusive force necessary for the engulfment of large beads points toward a large scale (0.5 um) strain energy stored in the cytoskeleton, and that the flattening force can plausibly be generated by the known concentrations of unconventional myosins at the leading edge.

255

**F-Actin Levels in Furrow Canals, but not Basal Junction Integrity, is Critical for Drosophila Cellularization**

A. Sokac,[1] E. Wieschaus[1,2]; [1]Department of Molecular Biology, Princeton University, Princeton, NJ, [2]Howard Hughes Medical Institute, Princeton, NJ

Drosophila cellularization is a modified form of cytokinesis, during which the plasma membrane invaginates around each of 6000 cortical nuclei to generate an epithelial sheet of adherent cells that exhibit apical/basal polarity. The process thus requires specialized proteins to coordinate simultaneous polarity establishment, cell-cell junction assembly and F-actin remodeling with a large-scale membrane invagination event. Nullo is a basic (pI 11.4), myristoylated protein that is essential for the initiation and progression of cellularization. Nullo localizes to the basal cell-cell junction that assembles during early cellularization; and in *nullo* loss-of-function embryos (*nullo*X) both basal junctions and the adjacent F-actin/Myosin-2 furrow canals (FC) are disrupted. Since it was previously suggested that basal junctions are required for FC formation and/or stability, we examined embryos deficient for the basal junction component β-catenin. These embryos do not assemble basal junctions. Nonetheless, cellularization proceeds with normal FCs that are functional as indicated by their Myosin-2-based constriction in late cellularization. Quantitative analysis of confocal images further revealed that FCs in β-catenin-deficient embryos contain wild-type levels of F-actin throughout cellularization. We, thus conclude that basal junction disruption cannot account for the FC phenotype in *nullo*X embryos and instead Nullo may have a direct influence on F-actin remodeling at forming FCs. Indeed, F-actin levels in *nullo*X versus wild-type FCs is significantly decreased throughout cellularization. The FC disruption in *nullo*X mutants likely results from this decrease in F-actin levels as the phenotype is mimicked by treating wild-type embryos with low doses of cytochalasin-D. Furthermore, over-expression of Nullo increases F-actin levels in FCs. Thus Nullo modulates F-actin levels in forming FCs; and the F-actin level in FCs, but not basal junction integrity, is critical for cellularization to initiate and proceed.

**A Deeper Look into *Dictyostelium* PAKa's Posterior Cortical Localization**

S. Zhang, R. A. Firtel; Section of Cell and Developmental Biology and Center for Molecular Genetics, University of California, San Diego, La Jolla, CA

In *Dictyostelium*, PAKa is an important effector in the signaling pathways required for proper chemotaxis. PAKa and myosin II co-localize to the posterior cortex of chemotaxing cells, which suggests that PAKa might indirectly regulate myosin II assembly and contractility. This was confirmed by analysis of PAKa's null phenotype. The N-terminus of PAKa was previously shown to be essential for PAKa's posterior localization. To explore the mechanism that regulates PAKa's localization, we created a series of truncated PAKa constructs fused to GFP and examined their subcellular localization in chemotaxing cells. We showed that the first 244 residues of the PAKa N-terminus are necessary and sufficient for PAKa's posterior cortical localization. Deletion of residues 1-40 caused a diffuse, cytosolic distribution of truncated PAKa(s) with no enrichment at the cell cortex. In contrast, the removal of amino acids 207-244 resulted in a loss of the posterior localization with the reporter localizing

uniformly along the cortex in unstimulated cells and enriched in the leading edge of chemotaxing cells. This finding suggested that the domains containing residues 1-40 and 207-244 might directly or indirectly associate with F-actin and myosin II filaments, respectively, leading to PAKa's localization in the posterior cortex. To further identify potential adaptor proteins linking PAKa to actomyosin, we performed a yeast two-hybrid screen and identified several proteins that interacted with the N-terminus of PAKa, including: *Dictyostelium* CBP3, an actin-associated calcium binding protein; sactin, a previously unidentified protein with actin-like and filamin-like domains; and ZAK1, an upstream regulator of *Dictyostelium* GSK3. Currently, we are analyzing these potential interacting proteins and their possible roles in controlling polarized PAKa distribution. We would like to thank Alan Kimmel for ZAK1 constructs and strains and Hyung-Soon Yim & San-Ouk Kang for CBP3 constructs and strains.

### Polarized Dynamics of Single Molecule G-protein Coupled Receptors in *Dictyostelium* Chemotaxis

S. de Keijzer,[1] A. Serge,[1] P. H. M. Lommerse,[1] F. van Hemert,[1] G. Lamers,[2] H. Spaink,[2] T. Schmidt,[1] B. Snaar-Jagalska[2]; [1]LION, Leiden University, Leiden, The Netherlands, [2]IBL, Leiden University, Leiden, The Netherlands

The directed cell movement, chemotaxis, of cells in response to shallow gradients of chemoattractants involves gradient sensing, polarity and motility. Recent evidence suggests that dynamic organization of proteins and lipids plays an important role. Based on confocal imaging, the signalling components of the chemotaxis pathway (like PI3K, PTEN, AC, CRAC, Akt/PKB, PhdA) in *Dictyostelium discoideum* have a polarized distribution upon cAMP stimulation. However, the cAMP receptor, cAR1, and the coupled G-protein β subunits are uniformly distributed along the cell surface. Since localization is not the only dynamic property of a receptor, the behaviour of single cAR1 on the apical membrane was followed in real time with Single Molecule Microscopy, where normal wide-field microscopy with laser excitation is combined with ultra-sensitive CCD camera detection. This gives us the possibility of detecting signals with a positional accuracy of 40 nm. We measured the diffusion of cAR1-YFP under different physiological conditions. In resting cells there were two diffusion fractions, a fast fraction with D = 0.19 $\mu m^2/s$ (38%) and an immobile fraction (62%). In polarized cells exposed to cAMP gradient we found a difference in the diffusion-behaviour between the anterior and the posterior. At the anterior a larger number of mobile receptors were observed. This motility shift was not because the fluidity of the membrane changed nor because of conformational changes of the receptor due to phosphorylation. We show that the motility shift of the receptors at the leading edge resembles the uncoupling/activation of Gα2-protein. We suggest a model in which the polarized dynamics of cAR1 amplifies the signal at the leading edge and accelerates intracellular signalling. This model adds a new mechanism explaining establishment of polarization upon gradient sensing during *Dictystelium* chemotaxis.

### A Centrin-based Cellular Spring that Generates nNs of Force

D. C. France,[1] V. Baru,[2] M. Shribak,[3] S. Inoue,[3] S. McCutcheon,[4] H. E. Buhse,[4] P. T. Matsudaira[1,2,5]; [1]Biological Engineering, Massachusetts Institute of Technology, Cambridge, MA, [2]Whitehead Institute for Biomedical Research, Cambridge, MA, [3]Marine Biological Laboratory, Woods Hole, MA, [4]Biological Sciences, University of Illinois at Chicago, Chicago, IL, [5]Biology, Massachusetts Institute of Technology, Cambridge, MA

The spasmoneme of the unicellular protozooan *Vorticella convallaria* is among the fastest and most powerful cellular engines known. A contractile organelle that uses calcium instead of ATP for energy, the spasmoneme is a bundle of fibers of undetermined composition. Centrin is the major component by dry-weight and the active calcium-binding element. Also found in filamentous structures associated with various actions ranging from spindle pole and centrosome movements to contraction of whole cell bodies, centrin may be the basis of a fourth cytoskeleton. To understand how centrin-based systems are involved in cell motility, we have been characterizing the structure, mechanics, and biochemistry of the spasmoneme and report several novel findings. First, the spasmoneme is a powerful cellular engine. We imaged spontaneous contractions while imposing a centrifugal force load on the cell body. At accelerations over 10000g, the cell body becomes tear-drop shaped, its contents become stratified, and yet the stalk still contracts. We estimate an upper bound on the amount of force generated during contraction in excess of 200 nN. Second, the current rubber-band model of the spasmoneme relies on a previously observed loss of spasmoneme birefringence in the contracted state, as oriented, birefringent fibers become disoriented with added calcium. In contrast, images from the orientation-independent polarized light microscope (LCPolScope) show the spasmoneme consists of fibers that retain some degree of order in the contracted state. Finally, we are able to correlate the structure and mechanics of the spasmoneme directly with centrin. After extracting the stalks under conditions which retain reversible calcium-dependent contractility, we find that one anti-*Vorticella* centrin antibody (anti-centrin 5) abolishes contractility while another (anti-centrin 4) does not. These observations suggest that the spasmoneme is a centrin-based mechanism that is unlike any actin or microtubule-based cellular engine, yet more powerful.

259

### Microtubule Targeting to Filopodia

J. M. Schober, Y. Komarova, O. Chaga, G. G. Borisy; Cell and Molecular Biology, Northwestern University, Chicago, IL

Microtubules are essential for formation of cell polarity and directed cell movement. Through alternating phases of shortening and growth, microtubule ends actively probe target sites in protrusive lamellipodia. Microtubules interact with filopodia in neuronal growth cones (A. Schaefer et al. 2002. *J. Cell Biol.* 158:139-152) and target adhesion sites in fibroblasts causing adhesion site dissociation (I. Kaverina et al. 1999. *J. Cell Biol.* 146:1033-1043). In our studies we identified interaction between microtubules and filopodia in B16F1 melanoma cells and NIH 3T3 fibroblasts. Following adhesion to fibronectin, cells exhibited protrusive lamellipodia with numerous filopodia. B16F1 cells that showed entry of microtubules into lamellipodia were scored for positive targeting events, defined as intersection of a microtubule end with the base of a filopodium. Analysis of digital images revealed targeting events at much greater frequencies than expected by chance. Live cell imaging demonstrated interaction between microtubules and filopodia in cells transfected with yellow fluorescent protein linked to tubulin and fascin, a specific marker of filopodia. Time-lapse sequences show multiple targeting events to filopodia at the protrusive edge of cells and microtubules buckling after targeting. Total internal reflection fluorescence microscopy images showed microtubules in close proximity to and below filopodia. Focal adhesion kinase and phosphotyrosine were not detected at microtubule target sites, suggesting interaction between microtubule ends and filopodia is independent of focal adhesions. To evaluate microtubule growth, cells were transfected with GFP-CLIP170, a plus-end binding protein that

highlights actively polymerizing microtubules. The GFP-CLIP170 reporter showed that microtubules actively polymerize along filopodia. These studies provide evidence for cross-talk between microtubules and filopodia, and suggest a potential mechanism by which microtubules may play an active role in cell protrusion. Supported by Training Grant no. NIH 2T32AG260-06 (JS) and NIH GM25062 (GGB).

**Focal Adhesions Area is Affected by Microtubule Acetylation**

A. Tran,[1] S. Che,[1] T. Yao,[2] J. Bulinski[1]; [1]Biological Sciences, Columbia University, New York, NY, [2]Pharmacology and Cancer Biology, Duke University, Durham, NC

Microtubules are subject to several reversible post-translational modifications, including acetylation. While the function of microtubule acetylation is unknown, manipulating the activity of HDAC6, a microtubule-selective deacetylase, has been shown to affect polarized cell migration. Overexpression of HDAC6 increases cell motility [1], while the specific inhibition of HDAC6 decreases cell motility [2]. We corroborated and expanded these results, observing that transformed cells are more potently affected than non-transformed ones. The role of microtubules in cell movement is still under investigation; however one possible way that microtubules might influence motility is through regulating focal adhesions [3]. Therefore, we hypothesized that changes in microtubule acetylation via modulation of HDAC6 activity would result in changes in focal adhesions. We monitored focal adhesions by quantifying paxillin localized to adhesions and found that short-time treatments of Trichostatin A (TSA), a general HDAC inhibitor, resulted in a time-dependent increase in focal adhesion area. Furthermore, washout of TSA resulted in a reversal, focal adhesion area returned to control levels. In cells over-expressing HDAC6, focal adhesion area was significantly decreased, compared to control cells, while in cells where HDAC6 had been knocked down by siRNA, focal adhesion area was significantly increased. Thus, manipulation of microtubule acetylation through changes in HDAC6 activity quantitatively alters the cell's focal adhesions, although whether the mechanism involves altered elaboration or turnover of adhesions is thus far unknown. This change in focal adhesion, perhaps or in cooperation with other mechanisms, is a likely contributor to the observed change in cell motility upon modulation of HDAC6. [1]

261

**Regulation of the MSP Polymerization that Generates Leading Edge Protrusion in *Ascaris* Sperm**

K. Yi,[1] S. M. Buttery,[1] M. Stewart,[2] T. M. Roberts[1]; [1]Department of Biological Science, Florida State University, Tallahassee, FL, [2]MRC laboratory of Molecular Biology, Cambridge, United Kingdom

Leading edge protrusion in the amoeboid sperm of *Ascaris suum* is driven by localized assembly of the MSP cytoskeleton. This process is orchestrated by an integral membrane phosphoprotein, MPOP, but also requires additional cytosolic components. MSP-based protrusion has been reconstituted *in vitro*; vesicles derived from the sperm plasma membrane are pushed by elongation of a columnar meshwork of MSP filaments, called a fiber. The motility apparatus contains a MW ~34 kDa protein (p34) that has a conserved kinase domain. This protein co-localized with MPOP at the vesicle-fiber interface, the site of MSP polymerization and protrusive force generation in the *in vitro* motility system. Moreover, binding assays showed that p34 interacts specifically with phosphorylated MPOP and also with a 47 kDa cytosolic protein that we designated MSP fiber protein 3 (MFP3). Immunolabelling demonstrated that MFP3 is localized throughout the fiber, and functional assays demonstrated that MFP3 is necessary for maintaining fiber structure. Sequence analysis suggests that MFP3 is a serine/threonine phosphoprotein. These results indicate that MPOP, p34 kinase and MFP3 may form a complex to nucleate and regulate MSP polymerization at the membrane surface. Supported by NIH Grant GM 29994.

**Characterization of the Roles for the Na,K-ATPase Alpha and NHE Isoforms in Mouse Sperm Motility**

S. Chakraborty, A. Sengupta, P. F. James; Zoology, Miami University, Oxford, OH

The ion signaling pathways that activate and maintain sperm motility are multifactorial and remain incompletely resolved. Recent studies using inhibitors and ionophores have demonstrated a role for the rat Na,K-ATPase alpha4 isoform, in conjunction with one or more NHE isoforms, in maintaining sperm intracellular pH and motility. Three NHE isoforms (NHE1, NHE5, and spNHE) and two Na,K-ATPase alpha isoforms (alpha1 and alpha4) are expressed in rodent sperm. Targeted deletion of spNHE results in immotile sperm and infertility in mice however deletion of NHE1 doesn't affect fertility. No information concerning the role of NHE5 in sperm motility is available. The existence of a functional mouse Na,K-ATPase alpha4 isoform necessary for maintaining sperm motility, as in the rat, has not been demonstrated and the role that the Na,K-ATPase alpha1 isoform plays in sperm motility is unknown. Furthermore, the functional relationships between the Na,K-ATPase and NHE isoforms found in sperm are unresolved. The availability of Na,K-ATPase alpha1 heterozygous and homozygous NHE1 and spNHE knockout mice provides a unique set of reagents to dissect out the individual roles played by the Na,K-ATPase alpha and NHE isoforms in sperm. Here, we have cloned the cDNA and characterized the mouse Na,K-ATPase alpha4 isoform protein. As in rat, this mouse protein is expressed in the sperm flagellum and is necessary for normal motility. We have also determined that loss of all NHE1 or 50% of Na,K-ATPase alpha1 does not alter motility suggesting that these isoforms play roles unrelated to motility or that other isoforms compensate for their loss. Interestingly, we have demonstrated an upregulation of the Na,K-ATPase alpha4 protein, but not alpha1 or NHE5, in NHE1 knockout testes suggesting a functional relationship for NHE1 and the Na,K-ATPase alpha4 isoform in sperm physiology.

263

**Localization and Developmental Expression of the Human Na,K-ATPase Alpha4 Isoform in Sperm**

A. Sengupta,[1] S. Chakraborty,[1] T. Hlivko,[2] P. F. James[1]; [1]Zoology, Miami University, Oxford, OH, [2]Pathology, Suma Health System/ACH, Akron, OH

The Na,K-ATPase is an integral transmembrane protein, minimally composed of an alpha and a beta subunit. In humans three alpha isoforms (α1, α2, and α3) have been well documented. In rodents a fourth isoform (α4) has been identified and shown to be critical to maintaining sperm motility likely via its effects on a $Na^+/H^+$ exchanger (NHE) found in sperm. Recently we have characterized the human Na,K-ATPase α4 isoform and localized its expression to sperm in human testes. Here we have demonstrated the expression of the alpha4 protein in human sperm lysates but not in human kidney, skeletal muscle and brain lysates by Western blot analysis and specifically localize the Na,K-ATPase alpha4 protein to the

principle piece of the human sperm flagellum using immunofluorescence. In addition, we demonstrate that the Na,K-ATPase α4 expression appears only after sexual maturity in humans: the alpha4 protein is present in the sperm flagellum in testes from a 16 year old individual but not in testes from 3 month, 6 year, 9 year, or 10 year olds. This data demonstrates that the expression of the human alpha4 protein is developmentally regulated and its expression occurs with the appearance of mature sperm. Specific inhibition of the rat Na,K-ATPase alpha4 isoform with the cardiac glycoside ouabain results in loss of sperm motility. Motility can be restored to alpha4-inhibited sperm with ionophores that move $H^+$ suggesting that this isoform is essential to the activity of a NHE which regulates intracellular sperm pH. Here we demonstrate restoration of motility to alpha4-inhibited sperm using ammonium chloride or the cAMP analogue 8-Br-cAMP. This data further supports the link between Na,K-ATPase alpha4 inhibition-induced loss of sperm motility and alteration in intracellular pH and suggests that this occurs via a cAMP-mediated pathway.

**Spatial Localization of M-Calpain to the Plasma Membrane by $PIP_2$ binding is Required for EGF Receptor-Mediated Activation**

H. Shao,[1] J. Chou,[1] D. Stolz,[2] C. J. Baty,[2] A. Wells[1]; [1]Pathology, University of Pittsburgh, Pittsburgh, PA, [2]Cell Biology, University of Pittsburgh, Pittsburgh, PA

Cell motility is critical for wound repair and tumor invasion. Calpain activity is required for rear de-adhesion during both haptokinesis and chemokinesis of fibroblasts and epithelial cells. Growth factors activate m-calpain (CAPN2) via the ERK MAP (mitogen-activated protein) kinases, but only when these kinases are localized to the plasma membrane. We thus hypothesized that m-calpain is activated by epidermal growth factor (EGF) only when it is juxtaposed to the plasma membrane secondary to specific docking site(s). Osmotic disruption of NR6 fibroblasts demonstrated a significant portion of m-calpain being complexed with the substratum-adherent membrane; the amount of m-calpain at the membrane increased in an EGF-dependent manner. In vitro, purified m-calpain bound to nylon-immobilized phosphoinositides but not other phospholipids. This was mirrored in vivo as removal of phosphoinositide bisphosphate ($PIP_2$) by bacterial phospholipase C released the bound m-calpain. This binding capacity was found to reside in isolation to Domain III of calpain, which has a putative C2-like domain. Activation of m-calpain by phosphorylation at serine 50 was found to increase m-calpain binding to the membrane. In vivo, downregulation of phosphoinositide production by 1-butanol, resulting in diminished PIP2 in the plasma membrane, and eliminated EGF-induced calpain activation but not MEK activity. Immunostaining and immunoblotting of the membrane footprints showed that PI-PLC and 1-butanol limited the membrane association of m-calpain. Importantly, we found m-calpain was accumulated at the rear of both intact cell and plasma membrane footprint in wound healing area; EGF enhanced this m-calpain accumulation to the rear. These data support a model of m-calpain binding to $PIP_2$ to enable ERK activation, and provides a mechanism by which cell de-adhesion is directed to cell body and tail as PLCγ hydrolyses PIP2 in the protruding lamellipodia.

**Proliferation and Chemotaxis of *Dictyostelium* Amoebae are Inhibited by Naringenin, a Flavonoid Compound Enriched in Grapefruits**

M. Russ, R. Martinez, P. Steimle; Biology, University of North Carolina at Greensboro, Greensboro, NC

Naringenin, a flavanone compound, has been shown to affect critical cellular processes such as glucose uptake, cell division, and possibly cell migration; all of these processes are involved in the cancer cell phenotype. As a result, there has been considerable interest in defining the mechanisms by which naringenin exerts its effects on cells. In this study, we have used the social amoeba, *Dictyostelium discoideum*, as a model system for examining the cellular processes and signaling pathways affected by naringenin. We found that *Dictyostelium* cell division is inhibited in a dose-dependent manner by naringenin ($IC_{50}$~100 μM). Naringenin-based inhibition of *Dictyostelium* proliferation does not appear to be due to cell death since cell viability is not affected by growth-inhibiting levels of naringenin. Naringenin (50 μM) also inhibits aggregation of *Dictyostelium* cells during the early stages of multi-cellular development, suggesting that this compound may interfere with chemotactic signaling. Parallel under-agarose assays showed that naringenin inhibits *Dictyostelium* chemotaxis towards folic acid. Numerous studies in *Dictyostelium* have established that the localized synthesis of phosphatidylinositol 3,4,5-trisphosphate ($PIP_3$) by PI3 kinase is a crucial early step in the chemotaxis signaling pathway. Since naringenin is an effective inhibitor of PI3 kinase activity, we explored that hypothesis that naringenin inhibits *Dictyostelium* chemotaxis by blocking PI3 kinase activity. To this end, we assayed live *Dictyostelium* cells for chemoattractant-stimulated translocation of a $PIP_3$-specific PH domain in the presence and absence of naringenin. Surprisingly, we found naringenin did not alter the rapid and localized increase in $PIP_3$ synthesis in response to chemoattractant stimulation of *Dictyostelium* cells, suggesting that naringenin may affect cellular migration via a previously unrecognized mechanism.

## Centrosomes I (266-281)

266

**G1 Cell Cycle Progression After Centrosome Removal**

Y. Uetake,[1] C. N. English,[1] A. Khodjakov,[2] G. Sluder[1]; [1]UMass Medical School, Worcester, MA, [2]Wadsworth Ctr, Albany, NY

Several studies indicate that the centrosome is required for G1 cell cycle progression in untransformed mammalian somatic cells. However, the fact that Hela cells, finishing mitosis without a centrosome, progress through S into the next mitosis demonstrates that centrosomes are not absolutely required for G1 progression in transformed cells (La Terra et al. J Cell Biol. 168:713, 2005). Presumably suppression of p53 and/or other aspects of transformation abrogate the mechanisms that detect centrosome loss or damage. To further investigate the involvement of the centrosome in G1 cell cycle progression we microsurgically remove the centrosome from hTERT-RPE1 cells stably transfected with human centrin-1/GFP. These cells have normal p53 function, because DNA damage leads to a rise in p53 levels and cell cycle arrest. When we remove the centrosome as early as 1 hour into G1, all karyoplasts (acentrosomal cells) progress through interphase into mitosis and divide. Surprisingly, the daughter karyoplasts incorporate BrdU and continued to divide (25/26). We then cut cells in G2 to remove one centrosome. 20 cells enter mitosis within 6 hours after the cut, assemble a spindle lacking one centrosome, and divide in a normal bipolar fashion to give a daughter with a centrosome and one without a centrosome. Of the acentriolar daughters, 10 progress to another mitosis, 4 arrest in G1 and 6 arrest in G2. Additionally, the acentrosomal karyoplasts form 0-8 bright focal centrin spots after centrosome removal in G1 or G2, suggesting *de novo* centriole assembly. These results provide the first indication that normal p53 positive human cells may progress through G1 after centrosomal removal and form centrioles *de novo*.

**Cryo Em Tomography and Averaging of Assymetric Structures: Application to γTuRC and the Microtubule Minus End**

J. M. Lyle, P. Koenig, D. A. Agard; Biochemistry & Biophysics, UCSF, San Francisco, CA

Microtubules are nucleated from the centrosome by the gamma-tubulin ring complex (γTuRC), a 2.2 MDa protein complex with a lock washer shape complementing the end of the microtubule (MT). While this complex is found free in the cytosol, its nucleation activity is largely restricted to the centrosome. In order to gain insights into the mechanisms of nucleation by the γTuRC and the origins of the functional differences between solution and bound to the centrosome, I am working to determine the structure of the microtubule nucleation site as it actually exists in the centrosome and to compare it to the structure of the isolated γTuRC. Using cryo electron microscopic tomography it is possible to directly visualize the nucleation machinery at the MT minus ends at about 5nm resolution. In an effort to better define the nucleation site, I am helping to develop software designed to find, align and average the minus end density, with a goal of reaching 2.5nm resolution. Our current reconstructions clearly show the γ-TuRC cap and also reveal the fibrous nature of the pericentriolar material (PCM). Using isolated γTuRCs and similar reconstruction approaches, I am building a higher resolution structure of this template of microtubule nucleation. My current structure, at approximately 2.5nm resolution, demonstrates the lock washer shape of the γTuRC, likely made up from the lateral association of γ-tubulin small complexes (γTuSC) and the existence of an additional cap structure that may act to stabilize the ring of γTuSCs. Comparisons of the three-dimensional structures of γ-TuRC will be discussed along with their implications for the mechanism of nucleation.

268

**Kinesin-like Protein Binding to a Conserved Domain in Gamma-tubulin Regulates Spindle Assembly and Mitotic Exit**

J. L. Paluh,[1] A. S. Rodriguez,[1] K. Mohan,[1] C. L. Mayer,[1] A. N. Killilea[2]; [1]Biology, Boston College, Chestnut Hill, MA, [2]Lawrence Berkeley National Labs, Berkeley, CA

In eukaryotes, correct bipolar spindle assembly and fidelity in chromosome segregation requires the coordinated action of kinesin-like proteins and is monitored by Mad2p, a component of the spindle assembly checkpoint. At kinetochores, the kinesin-like protein CenpE plays important roles both in chromosome segregation and in the spindle assembly checkpoint. What role kinesin-like proteins play at microtubule ends of spindle poles, possibly through interactions with microtubule organizing center proteins, has not been determined. In addition, localization of Mad2p to poles preceding anaphase, is conserved but is not understood. Members of the ubiquitous Ncd/Kar3 family of kinesin-like proteins are implicated in regulation of microtubule number, organization, minus-end dynamics and γ-tubulin function. Our findings indicate that in fission yeast the kinesin-like protein Pkl1p binds to γ-tubulin to regulate both bipolar spindle assembly and post-metaphase localization of Mad2p to poles. Former models propose Ncd/Kar3 family kinesin-like proteins exert forces primarily along interdigitating microtubules, with this action deterring that of similarly positioned BimC motors in pushing spindle poles apart. We identified residues on γ-tubulin for Pkl1p binding. These represent a subset of invariant residues present in the same domain of β-tubulin but absent in α-tubulins. Mutation of this γ-tubulin domain to disrupt Pkl1p binding is sufficient to rescue bipolarity in a *cut7-22* (BimC) mutant and mimics *pkl1Δ*. Distal chromatin-microtubule interactions also contribute to oppose Pkl1p. We present a revised three-point model for bipolar spindle assembly based on genetic, molecular biochemical and cell biological analysis and discuss implications of our work on kinesin-like protein binding to γ-tubulin versus β-tubulin families. We propose that Pkl1p at poles, similar to CenpE at kinetochores, may play dual roles in regulating microtubule minus-ends and providing a link to Mad2p.

269

**Dynein and Dynactin are Involved in Anchoring of Microtubules at the Centrosome in Interphase Cells**

O. Kovalenko,[1,2] E. Nadezhdina,[2] V. I. Rodionov[1]; [1]Cell Biology, University of Connecticut Health Center, Farmington, CT, [2]Belozersky Institute of Physico-Chemical Biology, Moscow State University, Moscow, Russian Federation

Cytoplasmic dynein and its cofactor dynactin are known to be involved in the establishment and maintenance of the centrosomal radial microtubule (MT) array in interphase cells, but their roles in the attainment of the radial MT organization is not clear. It has been suggested that dynein/dynactin complex contributes to this process by transporting MT nucleation sites to the centrosome in the form of gamma-tubulin/pericentrin complexes and possibly by directly inducing MT nucleation at the centrosome. It has also been found that dynactin can participate in the anchoring of MT minus ends at the centrosome. To examine the role of dynein/dynactin in the MT radial array maintenance in interphase cells, we studied the behavior of a MT radial array in Vero cells labeled with Cy3-tubulin and injected with dynein/dynactin inhibitors, a function-blocking dynein antibody, or recombinant p50 subunit of dynactin that disrupts the dynactin complex. We found that both inhibitors induced rapid (~60 min) loss of radial MT organization in most of the injected cells without affecting the levels or localization pattern of major centrosomal proteins gamma-tubulin, pericentrin, and ninein, suggesting that dynein/dynactin are not involved in transport of these components to the centrosome after the radial array establishment. Moreover, MT nucleation rates at the centrosome measured by counting of the number of EB1-GFP comets emerging from the centrosmal region also remained unchanged in the presence of the inhibitors, indicating that MT nucleation on the centrosome does not require the intact dynein/dynactin complex. We conclude that while both dynein and dynactin are essential for the maintenance of the radial MT organization, their primary role is independent of MT nucleation and consists of anchoring of the minus ends of the MTs nucleated at the centrosome.

270

**Analysis of the Interaction Between *Drosophila* Pericentrin Like Protein (D-PLP) and the Dynein Complex**

N. Peel, T. M. P. Barros, E. Lucas, J. W. Raff; Wellcome CR UK Gurdon Institute, Cambridge, United Kingdom

The *Drosophila* pericentrin like protein (D-PLP) is localised to centrioles and pericentriolar material (PCM). In fixed *d-plp* mutant larval brains PCM components are not efficiently localised to the centrosome (Martinez-Campos et al, 2004). We have undertaken a live analysis of the basis for this defect, in embryos. We generated germline clone embryos that lack D-PLP and also express GFP-fusions of PCM components. We show that, in the absence of D-PLP, PCM components are still recruited to the centrosome, but cannot be retained there. Instead, they are dispersed away from the centrosome in a microtubule dependent process. Thus, D-PLP appears to maintain the structural integrity of the centrosome by counteracting microtubule dependent dispersal of the PCM. How does D-PLP fulfil this role? It has been shown previously that vertebrate pericentrin interacts

with the cytoplasmic dynein complex. We are testing whether this interaction is conserved in fly, and if so, if it has a functional significance in the maintenance of PCM integrity. To this end, we have developed a new GFP-dynein-complex marker that we will use, in addition to p50-GFP, to test whether D-PLP plays a role in dynein localisation.

271

### Interaction of Cep135 with Centrosomal Proteins

K. Kim, S. Lee, J. Chang, K. Rhee; Department of Biological Sciences, Seoul National University, Seoul, Republic of Korea

In interphase cells, the centrosome acts as a microtubule organizing center for cell shaping, polarity and motility. In mitotic cells, it plays as the spindle pole for segregation of chromosomes. The centrosome consists of a pair of centrioles and the pericentriolar material. With a long term goal to understand protein networks of the centrosome, we have investigated specific associations among centrosomal proteins, including Cep135. The results suggested that Cep135 might function as a scaffold for maintenance of the centrosome structure.

272

### Characterization of a Centrin-Binding Protein in the Human Centrosome

J. Azimzadeh,[1] P. Hergert,[2] U. Euteneur,[3] L. Daviet,[4] A. Khodjakov,[2] M. Bornens[1]; [1]Umr144/cnrs, Institut Curie, Paris, France, [2]New York State Department of Health, Wadsworth Center, Albany, NY, [3]Institute for Cell Biology, LMU-ABI, Munich, Germany, [4]Hybrigenics SA, Paris, France

Centrin proteins are small calcium-binding proteins conserved in a wide range of eukaryotes. They have been detected in many different cellular structures, suggesting that they could have several distinct functions. Many of these seem to derive from an ancient association of centrin proteins with the flagellar apparatus. In yeast and human, centrins have been involved in centrosome duplication, but the precise mechanisms in which they are implicated remains elusive. To better understand the functions of centrin proteins in the human centrosome, we have used a two-hybrid approach to identify centrin-interacting proteins. This has led to the identification of p65 protein. Like centrin, the p65 protein is an ancient protein conserved in various eukaryotic lineages. p65 protein homologues are only found in the genomes of species that assemble canonical centrioles, reflecting a possible function in centriole structure assembly. p65 protein interacts with both ubiquitously expressed human centrin proteins, Cen2p and Cen3p, as confirmed by immuno-precipitation experiments and GST-pull downs assays. A specific antibody reveals an asymmetric staining of the two centrioles and shows that the protein is recruited to the forming pro-centrioles during late S or G2 phase. Immunogold-EM shows that, like centrin, p65 is localized in the distal part of the centriole lumen. RNAi inactivation of p65 did not reduce the staining of the mother centriole, suggesting a stable incorporation in the centriole structure. p65 staining of the daughter centriole was however suppressed, and cell viability strongly reduced in HeLa cells, whereas in RPE1 cells, an arrest in G1 was observed. Electron microscopy shows that most depleted cells present short pro-centrioles, suggesting a possible role of p65 in the assembly or maturation of the distal part of centrioles.

273

### Identification and Characterisation of the Novel Centrosome Component BC1

S. Elliott, J. Sante, T. Stearns; Biological Sciences, Stanford University, Stanford, CA

The centrosome is the major microtubule organising centre of the cell. Centrosomes are central to cytoplasmic organisation, chromosome segregation and cell division. The centrosome consists of two centrioles surrounded by pericentriolar material. The sperm basal body is very similar to the centrosome of somatic cells, however the sperm basal body does not contain many of the pericentriolar components of the centrosome. In an attempt to identify and analyse core centrosome components we fractionated sperm and focused on the fraction containing centrin. Centrin is a highly conserved protein known to localize to centrioles. Using mass spectrometry, we found that other known centrosome components and a number of uncharacterized proteins co-fractionated with centrin. One of these proteins, BC1, was chosen for further analysis. BC1 is a coiled-coil protein conserved in higher eukaryotes. BC1 localises to the sperm basal body and the centrosome in tissue culture cells. Purification of TAP-tagged BC1 from tissue culture cells has identified interacting partners and RNAi is being conducted to explore the function of BC1 in mammalian cells.

274

### CenpJ is a Novel Protein Required for Centriole Assembly

R. Basto,[1] J. Lau,[1] N. Peel,[1] C. G. Woods,[2] J. W. Raff[1]; [1]Wellcome Trust Cancer Research Gurdon Institute, University of Cambridge, United Kingdom, [2]Department of Medical Genetics, CIMR, University of Cambridge, United Kingdom

Centrosomes are the major microtubule-organizing centers (MTOC) of animal cells and as such play a role in various microtubule-related functions, including cell shape, motility and division. A centrosome consists of a pair of centrioles surrounded by pericentriolar material (PCM). Centrioles not only have an important role in organizing the PCM, they also can act as basal bodies, specialised structures that localise at the base of all cilia and flagella. The growing list of centrosome-associated proteins suggests that centrosomes could be involved in previously unsuspected cellular functions and centrosome dysfunctions could therefore contribute to the development of human diseases. CenpJ is a novel centrosome protein and mutations in the *cenpJ* locus in humans is thought to contribute to microcephaly, a neurodevelopmental disorder where brain size is reduced. We are currently using the genetic organism, *Drosophila melanogaster*, to investigate the cellular function(s) of CenpJ. We have found that CenpJ is localised to the centrioles throughout the cell cycle. Antibody injection experiments revealed that CenpJ is essential for both centriole replication and PCM recruitment.

275

### Dissecting the Centrosome Positioning Pathway

J. L. Feldman, W. F. Marshall; Biochemistry, University of California, San Francisco, San Francisco, CA

Although originally named for its central location within the cell, the centrosome often resides in more peripheral locations. Relocation of the centrosome within the cell, for example, during wound healing or migration, requires the shuttling of the centrosome to specific locations. Furthermore, centrioles, the core of the centrosome, also need to be targeted to specific cellular sites. For example, centrioles are localized to the apical end of the cell in order to make a cilium or flagellum. These movements are especially important during development, where the precise placement of a cilium in various cell types is critical. In the unicellular green alga *Chlamydomonas reinhardtii*, centrioles must be shuttled from

their central position during mitosis to their apical location during interphase. In order to understand how a centrosome is specifically positioned within a cell, we have employed a novel screen in *Chlamydomonas.* This screen takes advantage of the fact that properly positioned centrioles are required in order for cells to phototax; cells with aberrantly placed centrioles, and therefore aberrantly placed flagella, do not have the defined geometry between the eyespot (the light sensing organelle of the cell) and the flagella that is required for phototaxis. We have screened 10,000 lines for phototactic defects and have uncovered a number of interesting mutants that have defects in centriolar assembly and number. In addition, we have also uncovered a class of mutants, termed askew (asq), in which the centrioles are mislocalized within the cell. In asq mutants, centrioles lose their characteristic apical localization within the cell and are instead shifted to more lateral locations. Characterization of these mutants has helped us gain insight into the molecular mechanism by which centrosomes are properly localized and has revealed the extent of the instructive role of the centrosome in determining cellular geometry.

276

**Proteomic Analysis of Isolated *Chlamydomonas* Centrioles and Further Characterization of Candidate Proteins**

L. C. Keller,[1] E. P. Romijn,[2] I. Zamora,[1] J. R. Yates,[2] W. F. Marshall[1]; [1]Biochemistry, UCSF, San Francisco, CA, [2]The Scripps Research Institute, La Jolla, CA

The centriole is one of the most enigmatic organelles in the cell. Centrioles are cylindrical, microtubule-based barrels found at the core of the centrosome. Centrioles also act as basal bodies during interphase to nucleate the assembly of cilia and flagella. Much of the mystery surrounding centrioles stems from the fact that until recently, the protein composition of centrioles was largely unknown. We exploited *Chlamydomonas* to conduct the first direct proteomic analysis of isolated centrioles. Through a bioinformatics cross-validation method we were able to group candidate centriole proteins into two groups: Basal body proteins with Upregulated Genes (BUGs), which are likely to be involved in ciliogenesis, and Proteome Of Centriole proteins (POCs). Our proteomic analysis provides the groundwork for further analysis of proteins involved in assembly and maturation of the centriole. To test if candidate proteins are bona fide centriole components, GFP-fusion proteins are made and localized in Hela cells. To elucidate a centriole assembly pathway, shRNA constructed against each candidate protein are transfected into Hela cells to examine centriole defects. Preliminary results suggest that candidate proteins are necessary for centrosome stability.

277

**Tandem Affinity Purification in *Dictyostelium*: Search for Interactors of EB1 and DdCP224 at the Centrosome and the Microtubule Plus-ends**

K. V. Koch,[1] Y. Reinders,[2] A. Sickmann,[2] R. Graef[1]; [1]Cell Biology, A. Butenandt Institute LMU, Muenchen, Germany, [2]Protein Mass Spectrometry and Functional Proteomics Group, Rudolf-Virchow-Center for Experimental Biomedicine, Würzburg, Germany

EB1 and DdCP224 are centrosomal components that also localize to microtubule (MT) tips and interact with each other. DdCP224 is involved in centrosome duplication and cytokinesis whereas EB1 assists in spindle formation. At the MT tip these two proteins are part of a complex that links MTs to the cell cortex. DdCP224 and EB1 were shown to interact with dynein. In addition, DdCP224 coprecipitates with dynactin and DdLIS1. To obtain more detailed information on the interactions of these proteins tandem affinity purification of cytosolic protein complexes containing DdCP224 and DdEB1 was conducted. EB1 was used in its full length. DdCP224 is split into two parts to be able to distinguish between centrosomal and cortical interactors, since the C-terminus is sufficient for centrosomal binding whereas a cortical localization can be detected with an N-terminal construct. Mass spectrometrical analysis of the purified complexes was used to identify novel interactors of these proteins. Additionally, this approach verified the known interaction of EB1 and DdCP224 as well as an interaction of DdCP224 with tubulin. An interaction between TACC and the C-terminal part of DdCP224 was detected and similar to findings in *Drosophila*, the TACC domain is sufficient for the centrosomal localisation of the protein and the interaction with DdCP224.

278

**Identification and Characterization of Novel Centrosome Components**

D. Ducat,[1,2] S. Kawaguchi,[2] Y. Zheng[1,2]; [1]Johns Hopkins University, Baltimore, MD, [2]Carnegie Institution of Washington/HHMI, Baltimore, MD

Recent research is revealing an increasing role for the centrosome in regulating various cellular activities, including formation of cilia, control of cell cycle and organization of the mitotic spindle. Despite this, the molecular nature of the centriole and the surrounding pericentriolar material (PCM) remains poorly understood. In order to gain a better understanding of the components required for the assembly and function of the centrosome, we have isolated and characterized a fraction of Drosophila embryo extract that is enriched in centrosome complementing activity. This fraction is capable of restoring microtubule nucleation capacity to centrosomes that have been stripped of many centrosome-associated proteins by high-salt treatments. Mass-spectroscopy analysis has revealed 360 proteins in this fraction, including a number of known centrosome proteins. We have undertaken a phenotype-based RNAi screen using Drosophila S2 cells in order to identify proteins in this fraction that are involved in the regulation of the centrosome. Preliminary analysis has revealed a number of candidate proteins that may have previously unrecognized roles in regulating centrosome-related functions.

279

**The Use of Vertebrate Reverse Genetics in the Study of the Centrosomal TACC Proteins**

A. Barr,[1] F. Langevin,[2] F. Gergely[3]; [1]Department of Biochemistry, University of Cambridge, Cambridge, United Kingdom, [2]MRC Laboratory Of Molecular Biology, Cambridge, United Kingdom, [3]Department of Oncology, University of Cambridge, The Hutchison/MRC Research Centre, Cambridge, United Kingdom

The Transforming Acidic Coiled-coil Containing (TACC) family of proteins are centrosomal proteins characterised by a highly conserved TACC domain at their C-terminus, which is essential for their centrosomal localisation. There is only one TACC protein in flies while three TACC proteins have been identified in mammals and birds (TACC1, 2 and 3). Previous data from the laboratory revealed an interaction between the TACC proteins and the colonic and hepatic Tumour Overexpressed Gene (ch-Tog), a member of the XMAP215/dis1 microtubule-stabilising family. More recently, we described that TACC3 and ch-Tog co-operate in the formation of the bipolar spindle in mammalian cells. Our understanding however is still incomplete as for the functions of, and the relationship between, the vertebrate TACC proteins. To explore this

question, we are using the chicken B-cell line, DT40, that allows targeted gene disruption via homologous recombination. Our strategy is to knock out the TACC domain of each of the three chTACC proteins and hence create cell lines that carry one or more disrupted *tacc* genes; the ultimate aim being to obtain cells without any functional TACC protein. We found that knocking out TACC2 in chicken cells does not affect either the viability or the morphology of the cells, an observation consistent with published studies on the TACC2 knockout mouse. We are in the process of generating cell lines where TACC2 is mutated in combination with TACC1 or TACC3.

280

**HCA66 is a Novel Protein Associated with the Centrosome from S to M-phase**

X. Fant,[1] A. Merdes[2]; [1]Wellcome Trust Centre for Cell Biology, University of Edinburgh, Edinburgh, United Kingdom, [2]UMR2587, CNRS, Toulouse, France

Several proteins exhibit a dynamic association with the centrosome in a cell cycle dependent manner. For example, gamma-tubulin has been shown to accumulate temporarily at the centrosome before mitosis, resulting in an increase of microtubule nucleation during spindle formation. To investigate changes in the composition of the pericentriolar material during the cell cycle, centrosomes were isolated at different stages, such as G1 and S phase. Pericentriolar material was prepared by salt-stripping of centrosomes, and analyzed by gel electrophoresis followed by MALDI-TOF mass spectrometry. We identified HCA66, a novel protein that localizes to the centrosome as well as to the nucleolus. Antibodies were raised against recombinant HCA66. Consistent with biochemical data, immunofluorescence microscopy revealed that HCA66 is recruited to the centrosome in S phase and remains associated until the end of anaphase. The sequences responsible for centrosomal and nucleolar localization were mapped using GFP-fusion constructs. The first 86 amino-acids of HCA66 (GFP-HCA66-1-86) are sufficient to confer a centrosomal localization. Overexpression of GFP-HCA66-1-86 leads to an aggregation of the exogenous protein in the cytoplasm and to a loss of gamma-tubulin signal at the centrosome in most cells, impairing microtubule regrowth after cold induced depolymerization. Preliminary siRNA experiments show that decrease of HCA66 expression leads to cell death, suggesting an essential role of the protein.

281

**A Centrosome-Associated RNA Encoding RNA-Directed Nucleotide Polymerase**

M. C. Alliegro,[1] M. A. Alliegro,[1] R. E. Palazzo[2]; [1]Cell Biology, LSU Health Sciences Center, New Orleans, LA, [2]Biology, Rensselear Polytechnic Institute, Troy, NY

The centrosome in animal cells is composed of a pair of centrioles surrounded by a relatively ill-defined pericentriolar matrix. Centrosomes serve as the major microtubule organizing center (MTOC) in cells, carry the mother centriole which is the basal body progenitor, and organize the assembly of the mitotic spindle during cell division. In spite of their obvious significance and over 100 years of research, our understanding of centrosome composition, organization, and mechanisms of action is poor when compared with other organelles. Centrosomes duplicate only once per cell cyle to ensure development of a normal bipolar spindle. The initial event in centrosome duplication is centriole replication, which is generative, semiconservative, and independent of the nucleus. These and other observations have led to the proposal that centrosomes contain their own complement of nucleic acids, possibly representative of an organellar genome as has been described for mitochondria and chloroplasts. The consensus in the field is that centrosomes do not contain DNA, but may contain RNA. We have extracted a unique set of RNAs from isolated surf clam centrosomes (cRNAs) and show that the first transcript to be analyzed in depth contains a conserved RNA-directed nucleotide polymerase domain and is concentrated in, if not fully restricted to centrosomes. These results support the hypothesis that centrosomes contain an intrinsic complement of RNAs, and provide new opportunities to address this five decades-old question.

## Intracellular Movement (282-303)

282

**A Computational Model of Actin-dependent Melanosome Transport in Fish Retinal Pigment Epithelial (RPE) Cells**

D. Tacelosky,[1] S. Forman,[2] S. Cooper,[2] P. Heil,[2] C. King-Smith[1]; [1]Department of Biology, Saint Joseph's University, Philadelphia, PA, [2]Department of Math and Computer Science, Saint Joseph's University, Philadelphia, PA

Retinal pigment epithelial (RPE) cells from fish contain melanosomes, melanin-rich pigment granules, which undergo light-dependent migrations from the cell body through long apical projections in response to light. *In vitro*, exogenous cAMP triggers unidirectional melanosome aggregation, while cAMP washout with dopamine produces saltatory, bidirectional melanosome dispersion. Both aggregation and dispersion are dependent on the actin cytoskeleton, and isolated melanosomes support motility of actin filaments in *in vitro* motility assays, suggesting a role for myosin motors in melanosome movements. To better understand the mechanism of dispersion, we applied kinetic parameters of melanosome dispersion to a discrete-event computer simulation. Excursion time, length, and velocity data were collected from time-lapse microscopy videos and entered into the input analyzer of the Arena© discrete event simulation package. The lognormal distribution, which consistently generated a good fit to the data, was used in the simulation, which was written in C. The simulation treats all melanosomes as individual entities that begin fully aggregated at time 0, and progressively disperse in a series of randomized events. At the completion of an event, the simulation is updated with respect to melanosome position before advancing to the most imminent event. Simulation output closely mirrored the behavior of individual melanosomes during dispersion. For a three-dimensional rendering of melanosome dispersion, simulation algorithms were translated into programming codes for the computer visualization program, Alice©. The lognormal distribution used in the model describes the process of “multiplicative degradation”, where the amount of degradation accumulates, reaches a critical point, and results in failure. In the context of melanosome dispersion, “failure” might represent complete disengagement of myosin motors from the melanosome, or release of motors from the actin track, resulting in the observed saltatory motility.

283

**Identification of AKAPs Involved in Regulation of Pigment Transport in Melanophores**

I. V. Semenova, P. Ivanov, V. Rodionov; Cell Biology, University of Connecticut Health Center, Farmington, CT

Aggregation and dispersion of pigment granules in melanophores is regulated by cAMP through the Protein Kinase A (PKA) signaling pathway.

We have recently shown that regulatory subunit of PKA is associated with pigment granules, where it forms complexes with molecular motors involved in pigment transport. We have also shown that association of PKA regulatory subunit with pigment granules occurs via binding to two A-Kinase Anchoring Proteins (AKAPs) with molecular masses ~80 kDa and 160 kDa. Here we have selectively extracted the two AKAPs from pigment granules and developed an experimental strategy for theis isolation and identification. Using this strategy we were able to isolate the 80kDa AKAP and identify it by mass spectrometry. We are now identifying the high molecular weight AKAP. The structure and molecular interactions of these proteins will provide insights into the molecular mechanisms of protein scaffolding on pigment granules that is critical for regulation of intracellular organelle transport.

284

**Pigment Organelle Tranport in Zebrafish - Using Forward Genetics to Identify Regulators of Molecular Motor Proteins**

L. Sheets,[1] E. M. Mellgren,[2] J. A. Kuhlman,[3] J. S. Eisen,[3] S. L. Johnson,[2] B. J. Schnapp[1]; [1]Cell and Developmental Biology, Oregon Health & Science University, Portland, OR, [2]Genetics, Washington University School of Medicine, St Louis, MO, [3]Institute of Neuroscience, University of Oregon, Eugene, OR

Fish melanophores are a valuable model system for investigating the molecular mechanisms of organelle transport because they aggregate or disperse their pigment granules (melanosomes) rapidly and coordinately in response to changes in intracellular levels of cAMP. Dispersion of melanosomes to the cell periphery occurs when intracellular cAMP levels are elevated and protein kinase A (PKA) is activated. Conversely, aggregation of melanosomes to the cell center occurs when cAMP levels are lowered and a phosphatase is activated. The downstream targets of PKA and the phosphatase are still unknown. We are interested in identifying these targets because they are likely regulators of molecular motor protein function. Previous studies in melanophores have employed species for which a forward genetic approach is impractical. The objective of our study is to use a forward genetic screen in zebrafish (*Danio rerio*) to identify proteins that regulate melanosome transport downstream of known signalling molecules. We have developed a screening assay that specifically identifies zebrafish mutants with melanosome transport defects. One of the mutants we have identified, *nermal*, is unable to fully disperse its melanosomes. We have analyzed melanosome movement in isolated *nermal* melanophores and our results indicate that the defective gene acts downstream of PKA and is involved in regulating microtubule based tranport. A second identified mutant, b867, is unable to evenly disperse its melanosomes. Analysis of isolated b867 melanophores indicates that the gene is involved in the instigation of actin-based transport. Our future aim is to identify the genes responsible for defective melanosome movement and uncover the function of these genes in organelle transport regulation.

**Alpha-herpesvirus Tegument Protein UL37 is Required for Intracellular Capsid Transport in Axons**

J. I. Lee, G. A. Smith; Microbiology/Immunology, Northwestern University, Chicago, IL

Alpha-herpesvirus infections of the vertebrate nervous system result in recurrent peripheral diseases or, less commonly, fatal encephalitis. The microtubule-based transport of capsids in axons is a critical determinant of disease, but occurs by an unknown mechanism. Previous work in our laboratory has demonstrated that actively transported capsids are associated with two viral tegument proteins, VP1/2 and UL37. We have made a recombinant virus lacking UL37 and expressing a red-fluorescence protein tagged capsid. Motions of capsids were monitored in both Vero cells and primary dorsal root ganglion neurons. Compared to the parent virus, capsids of the UL37-null virus displayed a defect in capsid transport. Future studies will focus on the mechanism of UL37-based intracellular capsid transport.

286

**Herpesviruses Use a Vesicular Transport Mechanism to Reach the Distal Axon**

S. E. Antinone, G. A. Smith; Microbiology-Immunology, Northwestern University, Chicago, IL

Alpha-herpesvirus infection of the vertebrate nervous system requires distinct steps of anterograde and retrograde transport in axons. The mechanism of axonal transport has, in part, been obscured by contradictory findings regarding whether capsids egress in axons as naked or enveloped particles. Determining the site of mature viral particle formation within neurons is not only critical to the mechanism of microtubule transport but is a fundamental problem to understanding directed spread of the virus from neurons to innervated tissues. To date, observations of viral assembly in axons have been made in fixed cells. In this report, we present the first study of herpesvirus maturation in living neurons. Separate viral components were simultaneously monitored in axons by fluorescence microscopy, and correlation of the motion of these structures was used to determine if capsids were enveloped during axonal egress. Several approaches were used to simultaneously image capsids and viral envelope structures, and all findings were consistent with maturation occurring in the neural soma and subsequent axonal transport using the secretory pathway.

287

**The Very Large Alpha-herpesvirus Tegument Protein, VP1/2, Co-sediments with Microtubules in an *in vitro* Assay**

G. W. G. Luxton, S. Haverlock, G. A. Smith, S. Rice; Northwestern University Feinberg School of Medicine, Chicago, IL

Alpha-herpesviruses are large, complex DNA viruses that spread throughout the mammalian nervous system by hijacking the endogenous axonal transport machinery of their hosts, allowing the viruses to travel undetected by the immune system. Although it is an important aspect of the infectious cycle, how these viruses interact with and regulate host transport proteins is unclear. Our recent work implicates the viral tegument proteins, located in between the capsid and envelope, in viral transport. We have found that tegument proteins remain associated with capsids as they move within axons sensory neurons during viral entry and egress (*Proc. Natl. Acad. Sci.* USA. 102(16): 5832-5837). We also have shown that the very large tegument protein, VP1/2, is required for microtubule-based capsid transport during viral egress in non-neuronal cells (*Submitted)*. To determine if VP1/2 directly interacts with microtubule motor proteins and therefore serves as a viral effector of capsid transport, co-sedimentation experiments were performed with microtubules (MTs) and extracts from 293 cells transiently expressing a GFP-VP1/2 fusion protein. VP1/2 only sedimented with MTs when dynein was also able to interact with the polymers. This result suggests that VP1/2 may directly tether the dynein to the capsid surface allowing for intracellular alpha-herpesvirus transport.

288

**Two Herpesvirus Kinases Modulate Plus-End Microtubule Transport in the Vertebrate Nervous System**

K. E. Coller,[1] G. T. Shubeita,[2] S. P. Gross,[2] G. A. Smith[1]; [1]Microbiology/ Immunology, Northwestern University, Chicago, IL, [2]Developmental and Cell Biology, University of California, Irvine, CA

Alpha herpesviruses use microtubule motors to transport bidirectionally in axons of the vertebrate nervous system. Targeted axonal transport is essential for the successful establishment of infection in peripheral ganglia (retrograde transport), and subsequent spread to exposed body surfaces following reactivation from latency (anterograde transport). Appropriate targeting of viral particles during infection requires upregulation of the anterograde component during egress, while the retrograde component remains constant during entry and egress. Two serine/threonine kinases, UL13 and Us3, are virally encoded and possess the potential to coordinate axonal transport. The effects of US3 and UL13 on axonal transport were investigated by infecting explanted dorsal root ganglia with fluorescent-tagged virus encoding mutations in these proteins. By live cell fluorescence microscopy, viral particles encoding kinase mutations transported retrograde similar to wild-type viral particles following infection. However, a mutant virus lacking Us3 and UL13 displayed an increase in minus-end motion during anterograde trafficking to axon terminals. Additionally, this mutant exhibited an increase in pauses and transient directional movements. These observations are consistent with the viral kinases regulating efficient anterograde transport by modification of the viral or host transport machinery.

**Translokin and Intracellular Trafficking of FGF2**

S. Meunier, C. Bossard, H. Prats, E. Lacazette; IFR 31, INSERM U589, Toulouse, France

FGF2 is one of the prototypes of the fibroblast growth factor family. It is involved in cell proliferation, developmental processes, wound healing, angiogenesis and tumour progression. Five FGF2 isoforms of 18, 22, 22.5, 24, 34K with different amino-termini are synthesised through an alternative translation initiation process. The secreted 18K form lacking an NLS can interact with membrane receptors and be internalized in the cytoplasm. It can also be translocated into the nucleus during the cell cycle. In order to identify proteins that can interact intracellularly with 18K FGF2 a yeast two-hybrid screening using it as bait allowed the identification of a protein called Translokin. Translokin has been recently shown to be involved in the nuclear tranlocation of the 18K form of FGF2. To further characterize the protein complexes involved in the intracellular trafficking of the 18K FGF2 a new yeast two hybrid screening has been made using Translokin as bait. One of the identified proteins is the sorting nexin 6 (SNX6). Initially SNX6 has been shown to interact with the TGFb receptor. These studies localized SNX6 in the cytoplasm where it is thought to target protein to the Trans-Golgi-Network. This makes SNX6 a potential candidate for sorting out FGF2 from the endocytosis vesicles allowing its trafficking to the nucleus. Another protein identified is the RanBPM protein. RanBPM was originally cloned for its ability to bind the small GTPase Ran. A cytoplasmic and nuclear distribution for the protein has been described. Even if the function of RanBPM is still unclear, it could be involved in the nuclear translocation of the 18K FGF2 form through its potential interaction with the Ran/Importin b pathway that mediates cargo import into the nucleus. Thus Translokin can be considered as an adaptor protein for the internalization of the 18K FGF2.

**Nuclear and Division Plane Positioning Studied with Optical Tweezers**

I. Tolic-Norrelykke,[1] L. Sacconi,[2] R. Isabel,[1] F. Pavone[2]; [1]Max Planck Institute of Molecular Cell Biology and Genetics, Dresden, Germany, [2]European Laboratory for Non-linear Spectroscopy, Sesto Fiorentiono (Florence), Italy

Cells of the fission yeast Schizosaccharomyces pombe have a centrally placed nucleus and divide by fission at the cell center. Microtubules are required for the central position of the nucleus, which in turn may determine the position of the division plane. Alternatively, the division plane may be positioned by the spindle, or by a morphogen gradient or a reaction diffusion mechanism. We investigated the role of microtubules in nuclear positioning, and the role of the nucleus in division plane positioning, by displacing the nucleus with optical tweezers. A displaced nucleus returned to the cell center by microtubule pushing against the cell tips. Nuclear displacement during interphase or early prophase resulted in asymmetric cell division, whereas displacement during prometaphase resulted in symmetric division as in unmanipulated cells. Thus our data suggest that the division plane is specified by the position of the nucleus in early prophase. This mechanism in fission yeast differs from that in animal cells, where the division plane is positioned by the anaphase spindle. Since the yeast nucleus is centered by microtubules during interphase but not in mitosis, the establishment of the division plane at the beginning of mitosis may be an optimal mechanism for accurate symmetric division of fission yeast cells.

291

**Nucleus Movement of Shear Polarized Fibroblasts is Mediated by Cdc42 and Microtubules**

J. S. Lee,[1] M. I. Chang,[1] Y. Tseng,[2] D. Wirtz[1]; [1]Chemical and Biomolecular Engineering, Johns Hopkins University, Baltimore, MD, [2]Chemical Engineering, University of Florida, Gainsville, FL

Nucleus migration is an essential function during nucleus positioning for tissue growth and development in eukaryotic cells. Despite such importance, the molecular regulators of nucleus movement in interphase fibroblasts have not been identified. Here, we demonstrate that the nucleus of Swiss 3T3 fibroblasts subjected to shear flow displays rigid-body movement and rotation, which depends mainly on the integrity of microtubules, not that of F-actin. Bulk depolymerization of F-actin structure caused minor changes in nucleus movement and shape, where as similar depolymerization of microtubules resulted in a more ductile and motile nucleus. Through inactivation of major members of Rho GTPases, well-known mediators of cytoskeleton reorganization, we find that Cdc42, not RhoA nor Rac1, controls the degree of rotation and extent of translational movements of the nucleus. These results establish Cdc42 as a molecular regulator of shear induced microtubule-dependent nucleus movement in Swiss 3T3 fibroblasts. *Mol Biol Cell. 2005 Feb;16(2):871-80

292

**Plasmids Traffic Along Microtubules During Transfections**

E. E. Vaughan, D. A. Dean; Pulmonary and Critical Care, Feinberg School of Medicine, Northwestern Univeristy, Chicago, IL

Little is known about how plasmids move through the cytoplasm to the nucleus during transfections. It has been suggested that the cytoskeleton

impedes free diffusion of DNA, implying that plasmids would be unable to reach the nucleus. Since transfections do work there must be mechanisms by which DNA circumvents cytoplasmic obstacles. One possibility is that plasmids move to the nucleus in a directed fashion using cytoskeletal motors. To address this, adherent, confluent cells were electroporated with a plasmid expressing luciferase. This provides a model for DNA movement not only applicable to electroporation but also to any type of gene therapy where the DNA becomes free in the cytoplasm (e.g. after endosomal escape). We found that perturbation of the actin cytoskeleton by either stabilization or breakdown did not affect the ability of plasmid to be expressed, suggesting that the actin network is not involved in the movement of DNA through the cytoplasm. In contrast, stabilization of the microtubule network increased reporter gene expression approximately five-fold in cultured cells. This suggests that microtubules are involved in transporting plasmids to the nucleus. Microinjections of a GFP-expressing plasmid in the presence of drugs demonstrated that disruption of the microtubule network resulted in drastically decreased expression. An *in vitro* spin-down assay confirmed these results and showed that DNA interacted with microtubules only in the presence of cell extract. Co-injection of anti-dyenin antibodies with a GFP expressing plasmid significantly decreased levels of GFP expression compared to control, suggesting that dynein is involved in this interaction. Taken together these results suggest that free plasmid moves along the microtubule network, via dynein, to reach the nucleus.

293

**Trafficking and Sorting of Vesicles Containing the Bile Salt Transporter Ntcp**

S. Sarkar,[1] E. Bananis,[1] M. S. Anwer,[2] A. W. Wolkoff,[1] J. W. Murray[1]; [1]Anatomy and Structural Biology and Liver Research Center, Albert Einstein College of Medicine, Bronx, NY, [2]Biomedical Sciences, Tufts University School of Veterinary Medicine, North Grafton, MA

Sodium dependent bile salt uptake by $Na^+$/taurocholate cotransporting polypeptide (ntcp) is increased within minutes following stimulation by cAMP, suggesting a readily available intracellular pool. Although it was proposed that intracellular ntcp cycles to and from the plasma membrane on microtubules (MTs), mechanistic details of this trafficking are not known. In the present study, ntcp-containing vesicles were identified in rat liver lysate and purified in an endocytic vesicle-containing fraction that also contained fluorescent vesicles due to pre-injection of liver with Texas red asialorosomucoid (ASOR) for 5 (early) or 15 (late) min before harvesting the liver. Vesicles were flowed into fluorescent microscopy chambers pre-coated with rhodamine-labeled MTs. Antibodies against ntcp, transferrin receptor, Rab11, Rab4, dynein, kinesin I and kinesin II, were used to determine localization on vesicles. Ntcp-containing vesicles bound to MTs and moved bidirectionally following 50μM ATP addition. Motility of these vesicles towards plus and minus-ends of MTs was mediated by kinesin I and dynein based on inhibition of motility by chemical inhibitors and specific antibodies. Ntcp-containing vesicles localized predominantly with recycling endocytic markers, although ~20% were coincident with early ASOR-containing vesicles. There was little colocalization of ntcp with late ASOR vesicles, suggesting that a segregation event occurred. In support of this possibility, ntcp-containing vesicles that colocalized with ASOR underwent fission, with one daughter vesicles enriched in ntcp (>75%) and de-enriched in ASOR (<18%). Fission was not seen in ntcp-containing vesicles that did not contain ASOR. These vesicles localized with Rab11, a marker of recycling endosomes. We conclude that the bile acid acid transporter, ntcp, has three subcellular localizations: plasma membrane, recycling endosomes and early endosomes. Regulation of the trafficking and consequent function of this integral membrane protein may have important consequences regarding the pathobiology of liver disease.

294

**Modulation of Organelle Transport by Intermediate Filaments**

V. I. Gelfand, M. Lakonishok, P. S. Fahrner, A. S. Serpinskaya, Y. Chou, R. D. Goldman; Cell and Molecular Biology, Northwestern University, Chicago, IL

The contribution of intermediate filaments (IF) to organelle transport was studied using cultured *Xenopus* melanophores. Melanophores move pigment organelles (melanosomes) along microtubules and actin filaments toward their periphery in response to high intracellular cAMP and toward the cell center in response to low cAMP. However, in addition to these two types of cytoskeletal filaments, melanophores possess a well developed network of vimentin IF extending from the perinuclear region to the cell surface. In order to investigate the role of IF in the movement and positioning of melanosomes, we transfected melanophores with a construct encoding a GFP-tagged fragment of vimentin including the N-terminus and the first 37 amino acids of the coiled-coil domain 1A. This construct is a dominant-negative disruptor of vimentin IF. The expressed protein was concentrated in perinuclear aggregates and no IF (either endogenous or GFP-tagged) could be detected in the remaining cytoplasm. The expression of GFP-tagged full-length vimentin cDNA, used as a control, assembled into endogenous IF networks that appeared identical to those found in untransfected cells. Comparisons of organelle movement in cells expressing the mutant protein with cells expressing the full-length GFP-tagged vimentin or untransfected cells demonstrated that the destruction of the vimentin IF network substantially increased the rate of movement of melanosomes along microtubules both toward the cell center and toward the cell periphery, but did not affect the final aggregated or dispersed state of pigment. Melanosomes purified from the cell extract by sedimentation through a Percoll cushion contain a substantial amount of vimentin suggesting that pigment organelles can bind to IF. These results suggest that IF play important roles in modulating organelle motility and their anchorage to target sites in the cytoplasm. Supported by grants to VG and RG from the NIGMS.

**Spatial and Temporal Dynamics of Vesicle Transport in *Drosophila* Segmental Nerve Axons Revealed by Particle Tracking**

G. Yang,[1] S. B. Shah,[2] G. F. Reis,[2] G. Danuser,[1] L. S. B. Goldstein[2]; [1]Dept. of Cell Biology, The Scripps Research Institute, La Jolla, CA, [2]Dept. of Cellular and Molecular Medicine, University of California San Diego, La Jolla, CA

Proper functioning of microtubule-based bidirectional vesicle transport within nerve axons is crucial for proper neuronal function. Movement of specific cargos can be directly observed through imaging different fluorescently labeled transport proteins. Combination of fluorescence imaging with genetic manipulation of specific components of the transport machinery makes it possible to probe the function and regulation mechanism of the transport process. However, for quantitative understanding and modeling of axonal transport at both single vesicle and ensemble levels, reliable and efficient computational tools must be developed to track vesicle motion and to generate complete spatial and temporal dynamics readouts. Vesicles constantly undergo dense antiparallel motion and crossing, merging, and splitting within the axon, posing a major challenge for computational tracking. We have developed a new particle tracking scheme using a modified optimal bipartite-graph assignment algorithm that is derived from quantitative fluorescent speckle microscopy. A novel graph flow algorithm has been developed to resolve track crossing, merging,

and splitting. Our software can reliably recover complete tracks of large numbers of vesicles and is suitable for high-throughput processing. Based on complete vesicle trajectories, new quantitative descriptors have also been developed to fully characterize the spatial and temporal dynamics of the transport process. We validated this scheme on *in vivo* movies of vesicle motion in *Drosophila melanogaster* larval axons. Movement of kinesin-associated cargoes was observed and measured by imaging expressed YFP fused to the C-terminal of human amyloid precursor protein (APP-YFP) in a subpopulation of *Drosophila* segmental nerves. We report heterogeneity in spatial and temporal dynamics in wild-type larvae. We also report changes in vesicle transport dynamics in larvae with mutation in the retrograde motor component dynein heavy chain.

296

**Regulating Bidirectional Transport: Structure-function Analysis of the Coordinator Klar**

D. Kim,[1] Y. Guo,[1] S. Cotton,[1] M. Zapata,[2] J. G. Gindhart,[2] M. A. Welte[1]; [1]Rosenstiel Center MS029, Brandeis University, Waltham, MA, [2]Biology, University of Richmond, Richmond, VA

Bidirectional transport along microtubules is crucial for many cellular processes, but how opposing motors work together to yield regulated net transport remains unresolved. In *Drosophila*, the Klar protein is important both for transport reversal of certain cargoes and for coordinating motors on individual organelles. Klar's molecular mode of action is unknown. We found that there are at least four distinct Klar isoforms: α, β, γ, δ. Using molecularly characterized alleles, we can disrupt various combinations of isoforms, to probe their developmental expression, intracellular localization, and function. α is necessary for migration of photoreceptor nuclei; β mediates transport of embryonic lipid droplets; δ and γ localize to the nuclear envelope in certain tissues. Comparison with other isoforms suggests that Klar β contains three functionally distinct regions: an N-terminus shared with α, a common core shared with α and δ, and the β-specific C-terminal LD domain. LD is necessary and sufficient to recruit Klar to lipid droplets and thus constitutes a cargo-specific targeting domain. In a yeast-two-hybrid assay, LD interacts with LSD2, a droplet-specific transport regulator. LSD2 is not a droplet receptor for LD, or vice versa, because LSD2 and Klar are recruited to lipid droplets independently of each other. For two additional proteins that interact with LD in yeast, we are currently testing for physical interactions with LD in vivo and in vitro and are analyzing phenotypes of single and double mutants. We propose that the β-specific LD domain not only mediates correct intracellular localization of Klar but also confers cargo-specific regulatory properties to Klar. As a C-terminal LD fragment is sufficient to target to droplets in cultured cells, droplet localization and binding of regulators may be mediated by distinct regions of LD.

297

**Hic-5, a Focal Adhesion LIM Protein, Organizes a Nuclear-cytoplasmic Shuttling Complex Through LIM-LIM Recognition Involved in Cell-cycle Control**

K. Mori, K. Nose, M. Shibanuma; Dept. of Microbiology, Showa University, Tokyo, Japan

Hic-5 is a protein most homologous to paxillin, consisting of four N-terminal LD and four C-terminal LIM domains, and along with serving as a scaffold for signaling at focal adhesions, it shuttles between the focal adhesions and the nucleus. We report here the unique property of the most C-terminal LIM domain of Hic-5 to dimerize and the identification of the new partners of Hic-5 that heterodimerize and communicate between the two compartments with Hic-5. The biological significance of the complex formation is also addressed. RESULTS: Biochemical and immunoprecipitation study showed that Hic-5 formed homodimers as well as heterodimers with two LIM-only scaffold proteins, CRP and PINCH, in marked contrast to paxillin. Hic-5 also interacted with ILK, suggesting the assembly of multiprotein signaling complexes including ILK based on docking of the two scaffold proteins, Hic-5 and PINCH. Further study showed that the interaction of Hic-5 and PINCH was mediated by their particular single LIM domains, and both proteins were primarily co-localizaed at focal adhesions. However, under leptomycin B (LMB) treatment, PINCH, similar to Hic-5, accumulated in the nucleus when co-expressed with Hic-5. This phenomenon was also dependent on the co-expression of ILK whose location remained in the cytoplasm. These results, together with the study using various mutants defective in the interaction and shuttling, suggested that the interaction with Hic-5 directed PINCH to shuttle between cytoplasm and the nucleus, depending on ILK in the cytoplasm. Similarly, CRP showed LMB-dependent nuclear accumulation in the presence of Hic-5 or else localized in actin stress fibers in the cytoplasm. When introducing interaction-defective mutants of Hic-5 and PINCH into cells, the inhibition of cell-cycle entry and BrdU incorporation was observed. The detailed mechanisms are now under investigation.

298

**Fbox8, a Fbox Protein with the Sec7 Domain, Makes Arf6 Refractory to Function via Ubiquitination**

H. Yano,[1] I. Kobayashi,[1,2] K. Miura,[1] K. Iwai,[3] Z. Ronai,[4] H. Sabe[1,2]; [1]Department of Molecular Biology, Osaka Bioscience Institute, Suita, Japan, [2]Graduate School of Biostudies, Kyoto University, Kyoto, Japan, [3]Department of Molecular Cell Biology, Graduate School of Medicine, Osaka City University, Osaka, Japan, [4]Signal Transduction Program, The Burnham Institute, La Jolla, CA

The small GTP-binding protein Arf6 plays pivotal roles in membrane and cytoskeletal remodeling at the cell periphery, and has been implicated in higher orders of the cellular functions. Here we show that Arf6 can be polyubiquitinated, and identified Fbox8, an Fbox protein bearing the sec7 domain, to be responsible for this ubiquitination. Arf6 ubiquitination occurred predominantly at particulate subcellular fraction. No clear evidence was obtained for immediate degradation of the ubiquitinated Arf6, while Fbox8 was also ubiquitinated and rapidly degraded via proteasome in the same sets of cells. We also show that Fbox8 is predominantly recruited to plasma membrane rufflings where Arf6 is expected to function upon EGF stimulation, and suggest that ubiquitinated Arf6 molecules may escape from being recognized by its regulators and effectors such as ARNO and AMAP1. Forced expression of Fbox8 blocked cancer cell invasion and receptor endocytosis. We propose that Fbox8 provides a novel mechanism of Arf6 regulation.

299

**Akt Mediates Growth Factors Induced Cell Motility through Increasing Serine Phosphorylation of Phospholipase C-γ1**

Y. Wang, Z. Wang; Cell Biology, University of Alberta, Edmonton, AB, Canada

Both Phospholipase C-γ1 (PLC-γ1) and Akt (Protein kinase B, PKB) are signaling proteins that play significant roles in the intracellular signaling mechanism utilized by receptor tyrosine kinases (RTKs) including epidermal growth factor (EGF) receptor (EGFR). EGFR can activate PLC-γ1 directly and can activate Akt indirectly through PI3K. Many data have shown that PLC-γ1 pathway and PI3K-Akt pathway interact each other.

However, it is not known whether PLC-γ1 binds to Akt and what is the function of this interaction. In this communication, we identified a novel interaction between PLC-γ1 and Akt. We demonstrated that the interaction is mediated by the binding of PLC-γ1 SH3 domain to Akt proline motifs. We also provide a novel model to depict how the interaction between PLC-γ1 SH3 domain and Akt proline motifs is dependent on EGF stimulation. In this model, phosphorylation of PLC-γ1 Y783 by EGF causes the conformational change of PLC-γ1 to allow the interaction of its SH3 domain with Akt proline motifs. Furthermore, we showed that the interaction between PLC-γ1 and Akt caused phosphorylation of PLC-γ1 S1248 and enhanced EGF-stimulated cell motility.

**Anomalous Diffusion in Living Cells**

M. Elsner,[1] M. Weiss,[2] T. Nilsson[1]; [1]Medical Biochemistry, Göteborg University, Göteborg, Sweden, [2]BIOMS, Group Cellular Biophysics, German Cancer Research Center, Heidelberg, Germany

Since the advent of advanced light microscopy techniques it has become possible to investigate diffusion properties of molecules in living systems and to exploit these properties to gain insight in the organisation of cells. For a long time the basic physico-chemical properties of the cytosol received little attention. Only since the late 90s it is widely recognized that the high concentration of macromolecular solutes in the cytosol lead to properties qualitatively different from an average buffer solution. This phenomenon has been termed 'molecular crowding'. It influences basic cellular processes like protein folding, enzyme kinetics and DNA condensation. Here, we investigated the diffusion properties of fluorescently labelled inert dextran polymers in the cytosol of living cells with fluorescence correlation spectroscopy. Using dextrans of different molecular weights we found that all show a size dependent anomalous subdiffusion in the cytosol of living cells. In anomalous subdiffusion the mean square (MSD) displacement of the diffusing particle does not grow linear with time as in normal diffusion, but MSD~ $t^{\alpha}$ with $\alpha<1$. We could rule out that higher order structures like the cytoskeleton or the Endoplasmic Reticulum cause the observed subdiffusion. In contrast, we could demonstrate that a high concentration of macromolecular solutes leads to the emergence of anomalous diffusion using computer simulations and *in vitro* measurements. The extent of the anomality depends of the concentration and sized distribution of the solutes, which should make it possible to use this property to define the extent of crowding in a given solution, e.g. the cytosol.[1] Anomalous diffusion is not only observed in the cytosol but is also observed on Golgi resident transmembrane proteins. All Golgi resident proteins investigated so far show anomalous subdiffusion, suggesting a complicated organisation of Golgi membranes. 1 Weiss M, Elsner M *et al.* Biophys J, (2004)

**Mitochondrial Transport and Location Within Axons Are Not Associated with Differences in Membrane Potential**

J. L. Verburg,[1] R. L. Morris,[2] P. J. Hollenbeck[1]; [1]Biological Sciences, Purdue University, West Lafayette, IN, [2]Biology, Wheaton College, Norton, MA

The transport and docking of mitochondria in neurons place them at sites in the cell presumed to have a high demand for ATP and/or calcium buffering. Once mitochondria are directed toward an appropriate region, the cell could further increase local ATP production by locally increasing mitochondrial membrane potential ($\Delta\Psi$). Using the dye JC-1 as a reporter, we found that mitochondria moving anterogradely had higher apparent $\Delta\Psi$ than those moving retrogradely, in agreement with published data (Miller and Sheetz, 2004). However, since JC-1 has been shown to form irreversible aggregates providing an overestimate of $\Delta\Psi$, we made in vivo measurements using the Nerstian dye tetramethylrhodamine methyl ester (TMRM), which equilibrates rapidly across the membrane and does not aggregate. Mitochondrial TMRM fluorescence is diminished by uncoupling agents and increased by inhibition of ATP synthase. Fluorescence values from mitochondria were collected and compared between different regions of the axon. Although TMRM reveals heterogeneity in mitochondrial $\Delta\Psi$, the intracellular variation is surprisingly small. The standard deviation in $\Delta\Psi$ among mitochondria within individual neurons is 3.5 times less than that found when mean $\Delta\Psi$ of mitochondria was compared among different cells. To assess possible regional differences in $\Delta\Psi$, mitochondrial TMRM fluorescence was compared among three regions of the axon: growth cones, branch points, and axonal shafts. No correlation was found between mitochondrial fluorescence and the location of mitochondria in the axon. Comparing the $\Delta\Psi$ of anterograde, retrograde, and non-moving mitochondria revealed no significant difference among these populations. The lack of intracellular variation of $\Delta\Psi$ when measured with TMRM suggests that growing neurons use global rather than local cues to control $\Delta\Psi$, and rely on the physical distribution of mitochondria to serve the needs of specific subcellular regions.

**Hsp90 Chaperon Activity Regulates GDI Function in Rab1 Recycling Pathway**

C. Y. Chen,[1] W. E. Balch[2]; [1]Department of Cell Biology, The Scripps Research Institute, La Jolla, CA, [2]Department of Cell Biology, Molecular Biology and the Institute for Childhood and Neglected Disease, The Scripps Research Institute, La Jolla, CA

Rab GTPase-regulated hubs directing vesicle tethering-fusion provide the framework for an integrated coding system, the *membrome* network (Gurkan et al. (2005) Mol. Biol. Cell, 16, 3847), which is responsible for generation of the membrane architecture of eukaryotic cells. Guanine nucleotide dissociation inhibitor (GDI) is a central component of the Rab GTPase cycle that retrieves prenylated Rab GTPases from the lipid bilayer to form a cytosolic GDI-Rab complex. We have previously shown that Hsp90 specific inhibitors, such as geldanamycin (GA) and radicicol, potently inhibit αGDI-dependent recycling of Rab3A at the synapse and neurotransmitter transmitter release (Sakisaka et al. (2002) EMBO J., 21, 6125). We now show that the recycling of the Rab1 GTPase involved in constitutive transport between the ER and the Golgi is regulated by an Hsp90 complex. We find that GA and radicicol prevent the ability of GDI to retrieve Rab1 from the Golgi membranes. Inhibition of Hsp90 activity targets Rab1 function, which blocks ER to Golgi transport and prevents Golgi re-assembly. It is well established that Hsp90 chaperon complex modulates the conformation of steroid hormone receptor (SHR) to bind its substrate, steroid hormone. The similarity between SHR/steroid hormone and GDI/Rab prenyl groups suggests that membrane-associated Hsp90 chaperone complex alters the structure of the recruited GDI to form a lipid-binding pocket that facilitates the retrieval of Rab prenyl groups from the lipid bilayer for recycling to the cytosol.

**Microtubule Acetylation Inhibits Directional Migration, Cellular Polarization and Bidirectional Vesicle Transport**

A. A. Salam,[1] D. A. Recinos,[1] T. P. Yao,[2] J. C. Bulinski[1]; [1]Biological Sciences and Pathology & Cell Biology, Columbia University, New York,

NY, [2]Pharmacology and Cancer Biology, Duke University, Durham, NC
During persistent directional migration, a cell orients intracellular organelles and vesicle trafficking towards its leading edge. Several studies have implicated the activity or level of a MT-selective deacetylase, HDAC6, or the level of acetylated (Ac) MTs in regulating cell motility and polarizing cells (Hubbert et al., Nature 417:455-458[2002]; Haggarty et al., PNAS 100:4389-4394[2003]; Serrador et al., Immunity 20:417-428[2004]). To test the hypothesis that increased MT acetylation (hyper-Ac MTs) limits directional motility by inhibiting cellular polarization, we utilized trichostatin A (TSA) to inhibit HDAC6 activity, thus acutely increasing Ac MTs. In wound-healing assays TSA treatment significantly decreased directional migration, concomitantly decreasing the polarization of four organelles, the MT organizing center (MTOC), the stable MT subset, the Golgi complex, and the vimentin network. We next tested whether HDAC6-inhibition is sufficient to hamper migration of wound-edge cells that had already polarized prior to TSA treatment; preliminary data show that increasing Ac MTs in pre-polarized cells inhibits velocity of migration and mislocalizes the MTOC and the Golgi complex. TSA-inhibited HDAC6 localizes to MTs in the presence of TSA (A.Tran, not shown), thus, we tested whether our results are attributable to hyper-Ac MTs or MT-bound, inhibited HDAC6, using cell lines deficient in HDAC6. Preliminary experiments showed that siRNA HDAC6 knockdown cells were markedly defective in directional motility. We next tested whether the level of Ac MTs or HDAC6 alters Golgi vesicle trafficking; polarization of the Golgi complex is known to contribute to directed cell migration. Consistent with our hypothesis, TSA treatment resulted in a significant decrease in bi-directional vesicle trafficking, as did lowering HDAC6 expression. Our results point to a possible mechanism by which Ac MTs may affect directional motility, and our data underscore the importance of this MT subset in modulating MT functions.

### Association of Keratin 8 but not Keratin 19 Variants with Inflammatory Bowel Disease

G. Tao,[1] Q. Zhou,[1] P. Strnad,[1] L. Zhang,[2] N. D. Madani,[1] S. R. Brant,[3] J. Cho,[4] M. B. Omary,[1] R. H. Duerr[2]; [1]Department of Medicine, Palo Alto VA and Stanford University, Palo Alto, CA, [2]Department of Medicine and Human Genetics, University of Pittsburgh, Pittsburgh, PA, [3]Department of Medicine, Johns Hopkins University, Baltimore, MD, [4]Department of Medicine, University of Chicago, Chicago, IL
Keratin 8 (K8)-null mice develop spontaneous colitis, and K8 variants are found in few patients with ulcerative colitis (UC) and Crohn's disease (CD) but the association did not reach statistical significance. We asked if mutations in K8 or K19, the major intestinal keratins, predispose to UC or CD. Exonic K8 and K19 regions were PCR-amplified using genomic DNA from 87 unrelated patients with CD, 100 patients with UC, and 70 unaffected volunteers. Mutations were analyzed using a WaveSystem™ and DNA sequencing. Presence of K8 variants was tested by Pyrosequencing™ in 401 nuclear families (396 independent families with 667 UC/CD-affected offspring) that contain both parents and at least one UC/CD-affected offspring. K19 variants were identified in UC/CD patients with a similar mutation frequency in the control group. In contrast, 16 of the 187 UC+CD patients harbored K8 heterozygous variants involving G61C (6 patients) and R340H/C (11 patients, including one compound heterozygous) that were not found in any of the volunteers ($p<0.03$). The R340→C variant is unique and has not been previously described. The number of heterozygous parents and minor allele frequencies for each variant in the nuclear family parents are G61C (11; 1.4%), R340C (1; 0.13%), and R340H (33; 4.1%). Transmission disequilibrium testing showed transmissions:nontransmissions=6:1 (CD) and 7:4 (UC) for G61C, 0:1 (CD) and 2:0 (UC) for R340C, and 19:13 (CD) and 10:13 (UC) for R340H and correlation with disease severity is being analyzed. Hence, K8 but not K19 variants are found at higher frequency in patients with UC and CD and may play a role in disease pathogenesis. Establishment of significant transmission disequilibrium will require a larger cohort. K8 variants could pose an increased risk for developing UC/CD or end-stage liver disease depending on additional genetic/environmental factors.

### Interaction Between the Intermediate Filament Protein Synemin and α-Actinin in Mammalian and Avian Muscle Cells

S. E. Veneziano,[1] R. C. Bhosle,[1] Z. Li,[2] D. Paulin,[2] R. M. Robson[1]; [1]Muscle Biology Group, Iowa State University, Ames, IA, [2]Biologie Moleculaire de la Differenciation, Universite Paris, Paris, France
Intermediate filaments (IFs) encircle skeletal muscle myofibrils at their Z-lines, thereby linking all adjacent myofibrils, and the Z-lines of the peripheral layer of myofibrils to costameres along the sarcolemma. Synemin is a large novel member of the IF protein superfamily and appears to play a critical cross-linking role within the muscle cell cytoskeleton. Avian synemin exists as one form, but at least two splice variants, a larger α-synemin (ortholog of avian synemin) and a smaller, β-synemin, are differentially expressed in mammalian skeletal and smooth muscle. Synemin forms heteropolymeric IFs with the major IF proteins desmin and/or vimentin. Previous experiments demonstrated that avian synemin binds to α-actinin, a major component of both skeletal muscle Z-lines and smooth muscle dense bodies. It is not clear whether functional differences exist between α- and β-synemins, or whether one or both of these mammalian isoforms interact with α-actinin. Our objectives were to determine if an interaction exists between synemin and α-actinin in mammalian skeletal and smooth muscle cells, to define the interaction sites within each protein, and to compare this interaction to that in avian skeletal muscle cells. Blot overlay experiments indicate the C-terminal tail region of α-synemin binds to both head and rod domains of α-actinin-2, whereas β-synemin does not. Co-immunoprecipitation studies indicate synemin and α-actinin interact within cultured mouse skeletal muscle cells, rat smooth muscle cells, and primary chick skeletal muscle cells. In eight-day primary chick skeletal muscle cell cultures, synemin organizes into a striated pattern and colocalizes with α-actinin. Our results indicate that mammalian α-synemin, but not β-synemin, interacts with α-actinin in both skeletal and smooth muscle, thereby playing an important role in cytoskeletal linkages in mammalian skeletal and smooth muscle cells. 306

### Interactions of Two Isoforms of Mammalian Synemin with Vinculin and Metavinculin

N. Sun,[1] Z. Li,[2] D. Paulin,[2] D. R. Critchley,[3] R. M. Robson[1]; [1]Muscle Biology Group, Iowa State University, Ames, IA, [2]Biologie Moléculaire de la différenciation, Universite Paris, Paris, France, [3]Department of Biochemistry, University of Leicester, Leicester, United Kingdom
Synemin is a unique member of the intermediate filament (IF) protein superfamily, and is present as two splice variants, α and β, in mammalian muscle cells. The larger α-synemin is considered an ortholog of avian muscle synemin, which is expressed as only one form. Neither avian

synemin nor the two mammalian synemin isoforms will form IFs by themselves, requiring other IF proteins such as desmin or vimentin to form heteropolymeric IFs. The heteropolymeric IFs surround the Z-lines of the myofibrils in striated muscle cells, and thereby link all adjacent myofibrils within the cell. The IFs also link the Z-lines of the peripheral layer of myofibrils to the costameres positioned periodically along and subjacent to the sarcolemma. The costameric protein vinculin was previously shown to interact with avian synemin. Human α-synemin exhibits approximately 35% sequence identity with its avian ortholog. Solid-phase protein binding assays (blot overlays) and GST pull-down assays reveal specific interaction of the human vinculin tail domain with human α-synemin, but not with the β-synemin isoform. The region of interaction is located within the very long C-terminal tail domain of α-synemin. Immunocytological staining of cultured rat smooth muscle cells shows co-localization of α-synemin and vinculin in both focal adhesions and membrane ruffles. Protein binding assays also reveal that α-synemin interacts with the tail domain of human metavinculin, which is a slightly larger isoform of vinculin. In GST pull-down assays, vinculin and metavinculin display somewhat differential binding characteristics for α-synemin. These results suggest the possibility of isoform-specific functional roles for α and β synemin and for vinculin and metavinculin within mammalian muscle cells. (Supported by USDA-CSREES-NRICGP Award 2003-35206-12823)

### A Novel Mutation Reveals a Role of Keratin 5 in Melanosome Distribution and Cell Shape

L. Planko,[1] R. Betz,[2] S. Pasternack,[2] R. Kruse,[3] H. Buessow,[4] T. M. Magin[1]; [1]Institut für Physiologische Chemie, Abteilung für Zellbiochemie and LIMES, Universität Bonn, Bonn, Germany, [2]Institut für Humangenetik, Universität Bonn, Bonn, Germany, [3]Dermatologische Klinik, Universität Düsseldorf, Düsseldorf, Germany, [4]Anatomisches Institut, Universität Bonn, Bonn, Germany

Epidermal fragility syndromes support the concept that keratins have a major role in protecting epithelia against mechanical trauma. Dominant mutations in K5 and K14 cause EBS, a disease of basal epidermis accompanied by cytolysis and aggregation of the keratin cytoskeleton. Recent observerations have indicated an additional function of keratins in signal transduction. This also raises the issue whether intermediate filament proteins function both in their insoluble and a soluble state and how the transition between the two states is regulated. Here, we describe a novel, dominant K5 mutation which does not cause aggregation of the keratin cytoskeleton but alters tissue morphology characterized by papillary downgrowth of the epidermis. Moreover, it affects melanosome distribution in keratinocytes. The insertion of a single nucleotide causes premature translation termination which encodes a shortened K5 polypeptide encompassing the head domain. By RT-PCR, we demonstrated the presence of the mutant mRNA, excluding nonsense-mediated decay. Upon stable transfection as a YFP fusion protein into cultured keratinocytes, the truncated YFP-K5 polypeptide displayed a diffuse cytoplasmic localization and was completely soluble following fractionation. Colocalization studies indicated no association with desmoplakin, unliked predicted by previous studies. Instead, we noted a partial colocalization with dynein intermediate chain which may be involved in melanosome transport in keratinocytes. By coimmunoprecipitation, we isolated candidate proteins interacting with the K5 head domain. We hypothesize that the soluble keratin fraction is strictly regulated and has a major role in melanosome transport and localization.

### A Supportive Role of Desmin in Early Cardiomyogenesis

M. Hofner, A. Höllrigl, S. Puz, M. Stary, G. Weitzer; Medical Biochemistry, Medical University Vienna, Vienna, Austria

Desmin contributes to the stability of the myocardium and mutant alleles co-segregate with cardiomyopathies. To understand the role of desmin in cardiomyogenic specification and differentiation we investigated early cardiomyogenesis in embryoid bodies made of embryonic stem cells expressing different *desmin* alleles. We demonstrated a supportive role of desmin during mesoderm specification and early differentiation of cardiomyocytes, and an important function of amino-terminally located and facultative phosphorylated serine residue in specification, differentiation and maintenance of the myocardial phenotype. Constitutive expression of *desmin* assisted early cardiomyogenesis by temporary upregulation of *brachyury*, *nkx2.5*, *mlc1v* and *mhcα*. Consecutive development of highly interconnected and synchronously beating cardiomyocyte clusters pointed at an improved cytodifferentiation of cardiomyocytes. Desmin null cardiomyocytes featured an opposite phenotype. Constitutive expression of amino-terminally truncated $desmin^{\Delta 1\text{-}48}$ interfered with cardiomyogenesis, induced early cell death of presumptive cardioblasts, caused temporary downregulation of mesodermal and myocardial transcription factors, and hampered myofibrillogenesis and survival of cardiomyocytes. Mutation of temporarily phosphorylated serine residues in the amino-terminal domain of desmin destructed cardiomyogenesis and myofibrillogenesis in a dominant negative fashion. Even before beating cardiomyocytes developed $desmin^{S6,7,8A}$ caused downregulation of the transcription factor genes *brachyury*, *goosecoid*, *nkx2.5* and *mef2C*, which was accompanied by increased apoptosis of presumptive cardioblasts. $Desmin^{S31,32A}$ attenuated cardiomyocyte proliferation and cell-cell interaction, however did not affect early cardiomyogenesis and expression of mesodermal and myocardial transcription factors. These results demonstrate the detrimental influence of mutated desmin on specification and cytodifferentiation of early cardiomyocytes and suggest a substantial involvement of desmin in the very beginning of cardiomyogenesis. This work was supported by grant from Austrian FWF and bm:bwk.

### Mechanism of Keratin Filament Remodeling under Flow in Cultured Human Alveolar Epithelial Cells

F. W. Flitney,[1] K. M. Ridge,[2] R. D. Goldman[1]; [1]Cell & Molecular Biology, Northwestern University, Chicago, IL, [2]Division of Pulmonary & Critical Care Medicine, Northwestern University, Chicago, IL

Fluid shear stress results in a restructuring of keratin IF in cultured lung epithelial cells (Ridge et al, JBC In Press). The mechanism underlying the response to flow has now been studied using human alveolar cells (A549). Cells stained with anti-K18 were found to contain numerous densely-packed, spherical particles distributed throughout the cytoplasm, masking the underlying IF network. However, a well-developed keratin IF network consisting of thin, predominantly straight tonofibrils was revealed when cells were fixed in methanol, which did not preserve the fluorescent particles. This suggests that the latter might represent a more soluble pool of non-polymerized keratin. Immunoblots demonstrated that K18 was present in the soluble fraction following extraction with TX-100 in IF stabilization buffer. When A549 cells were subjected to moderate fluid shear stress (7 dynes/cm$^2$, 2-6 h), the majority of the fluorescent particles disappeared and their loss correlated with a >95% decrease in the amount of K18 in the TX-100 soluble fraction. Furthermore, the thin bundles of IF were transformed by flow into much thicker, wavy tonofibrils

that were readily seen by both immunofluorescence and TEM. We conclude that A549 cells contain a significant 'pool' of soluble K18, estimated to be ~10-12% of the total amount present in the cell. Our results show that shear stress creates conditions that facilitate the incorporation of this soluble fraction into pre-existing IF, an adaptive response to flow that results in a more robust, mechanically-stable IF network. We suggest that the reconfigured network is stiffer and therefore better able to resist potentially damaging mechanical forces, such as those generated during mechanical ventilation of the fluid-filled, atelectatic lung in patients with acute lung injury. Supported by a grant from the National Heart, Lung and Blood Institute.

**Plectin-Controlled Intermediate Filament Cytoarchitecture Affects MAP Kinase-Mediated Stress Response and Migration of Cells**

S. Osmanagic-Myers, M. Gregor, G. Walko, S. Reipert, G. Wiche; Molecular Cell Biology, University of Vienna, Vienna, Austria

Plectin is a major intermediate filament (IF)-based cytolinker protein capable to interact with a variety of cytoskeletal structures and plasma membrane-bound junctional complexes. Beyond stabilizing cells and tissues mechanically, plectin regulates actin filament dynamics and serves as a scaffolding platform for signaling molecules. In this study we show that plectin deficiency is a cause of aberrant keratin and vimentin cytoskeleton organization due to a lack of orthogonal IF-crosslinking. Keratin networks in plectin-deficient cells were found to be more susceptible to osmotic shock-induced retraction from peripheral towards perinuclear areas. Similarly, okadaic acid-induced disruption of IFs, both in fibroblasts and keratinocytes, proceeded much faster when plectin was absent. In both cases, accelerated stress response of IFs was paralleled by faster activation kinetics of stress-activated MAP kinase p38. In contrast, already the basal activity of migration-controlling MAP kinase Erk2 was significantly elevated in plectin-deficient keratinocytes correlating with their increased migration potential as assessed in vitro. Our data establish a direct link between cytolinker-controlled IF cytoarchitecture and specific MAP kinase cascades mediating distinct cellular responses.

311

**Elastic and Plastic Behaviour of the Intermediate Filament Network in Keratinocytes**

D. S. Fudge,[1] D. Russell,[2] E. B. Lane,[2] A. W. Vogl[3]; [1]Integrative Biology, University of Guelph, Guelph, ON, Canada, [2]Cancer Research UK Cell Structure Research Group, University of Dundee, Dundee, United Kingdom, [3]Cellular and Physiological Sciences, Univ. of British Columbia, Vancouver, BC, Canada

Recent work on the properties of secreted intermediate filaments (IF) from hagfish suggest that bundles of IFs are much less stiff and far more extensible than previously believed. We tested whether the mechanical properties of IF bundles in cultured cells are consistent with the properties reported from secreted hagfish IFs. To do this, we constructed a custom stretching apparatus that allowed us to apply uniaxial strains of up to 150% to NEB K14-GFP human keratinocytes grown on silicone rubber membranes. This apparatus was mounted on a fluorescent microscope so that the IF network could be visualized as the cells were stretched. We used a similar apparatus to embed stretched cells for visualization using TEM. Our light microscopy results showed that the IF network survives cell strains up to 150% without obvious rupture. At low cell strains, IF bundles behaved elastically. At higher strains, however, deformation was plastic, i.e. IF bundles did not recover to their initial length when the stretching protocol was reversed. TEM images of stretched and control cells revealed that low uniaxial strain results primarily in a straightening of IF bundles, which tend to be wavy in unstretched cells. Higher strains resulted in more direct longitudinal loading of the IF bundles, with plastic behaviour likely arising from slippage between IFs in the bundle, or possibly even stretching of the IFs themselves. The remarkable extensibility and mechanical stability of the IF network demonstrated here suggest that the IF network functions to passively protect cells and tissues from dramatic stresses and/or deformations.

**Crescentin Imitates Cytoplasmic Intermediate Filaments *in vitro* and is Temporally Regulated *in vivo***

M. T. Cabeen,[1] N. Mücke,[2] H. Herrmann,[3] C. Jacobs-Wagner[1]; [1]Molecular, Cellular & Developmental Biology, Yale University, New Haven, CT, [2]Biophysics of Macromolecules, German Cancer Research Center, Heidelberg, Germany, [3]Cell Biology, German Cancer Research Center, Heidelberg, Germany

Crescentin is the first known bacterial homologue of an intermediate filament (IF) protein, and is required for the curved-rod morphology of *Caulobacter crescentus*. It localizes in wild-type cells to a prominent filamentous structure at their inner curvatures, consistent with a cytoskeletal function. We sought first to compare the *in vitro* biochemical properties of crescentin with those of eukaryotic IF proteins. We used analytical ultracentrifugation to show that purified wild-type crescentin exists as a soluble tetramer, similar to eukaryotic IF proteins such as vimentin. In the presence of magnesium ions, crescentin formed filamentous structures similar in appearance to eukaryotic IF. These results suggest that crescentin follows an assembly pathway similar to those of cytoplasmic IF proteins such as desmin and vimentin. Considering that cytoplasmic IF proteins are generally considered to have evolved from lamin-like IF proteins, these results are particularly interesting. To explore crescentin regulation in live cells, we took advantage of the genetic tractability of our bacterial system and made a strain bearing a xylose-inducible *creS* gene. Surprisingly, we found that induced expression of *creS*, rather than complementing the straight phenotype of a strain deleted for *creS*, slowed growth and caused division defects. To further explore this phenotype, we used fluorescence imaging of a strain bearing an inducible tetracysteine (TC)-tagged version of crescentin, which was specifically labeled with Lumio Green dye. This revealed that xylose-induced crescentin forms a thick, mislocalized filamentous structure that appears to prevent cytokinesis. However, when crescentin is overexpressed in a strain with a high-copy plasmid bearing *creS* and its native promoter, cells exhibit significantly increased curvature. This suggests that increased expression of crescentin increases curvature, but only when crescentin expression is temporally regulated by its promoter.

313

**Integrin β3 Mediates Interaction of Vimentin with Focal Contacts in Endothelial Cells**

R. Bhattacharya, J. C. Jones; Cell and Molecular Biology, Northwestern University, Chicago, IL

We have previously demonstrated that vimentin-type intermediate filaments (IFs), in addition to microfilaments, associate with αvβ3 integrin-positive focal contacts in endothelial cells. Moreover, we have provided evidence that vimentin regulates the size, dynamics and adhesive functions of focal contacts (Tsuruta and Jones, 2003). In this study we have investigated the role of integrins in mediating vimentin-focal contact interaction.

Knocking down β3 integrin expression levels in endothelial cells using siRNA results in up to a 70% decrease in the numbers of focal contacts showing association with IF. Moreover, when endothelial cells are plated on fibronectin-coated coverslips, focal contacts are depleted of β3 integrin and we again observe a dramatic decrease in vimentin-focal contact interaction. To provide further support for β3 integrin-mediated vimentin-focal contact interaction, we next transfected GFP-β3 integrin into cell lines lacking β3 integrin but containing vimentin. Specifically, in "parental" CHO cells the vimentin IF cytoskeleton is collapsed around the perinuclear space. In sharp contrast, in CHO cells in which we induced the expression of full-length β3 integrin (CHOwtβ3), vimentin fibers extend to β3 integrin-rich focal contacts at the cell periphery. We have also transfected GFP-vimentin into a cell line lacking vimentin but which expresses β3 integrin (MCF-7 human breast adenocarcinoma cells). In the transfected MCF-7 cells, vimentin squiggles and short vimentin fibers arise from peripheral focal contacts suggesting the intriguing possibility that focal contact sites may be involved in filament nucleation. These data provide evidence that β3 integrin mediates vimentin association with focal contact proteins and we suggest that the latter interaction plays an important role in regulating both focal contact dynamics and functions.

314

**The Production and Distribution of Hsp27 and Keratins Are Affected in Keratinocytes Subjected to Mechanical Stress**

O. Duverger,[1,2] M. Moreau,[1,2] S. Schnebert,[1] C. Nizard[1,2]; [1]R&D LVMH Parfums et Cosmetiques, Saint Jean de Braye, France, [2]INSERM U505, Paris, France

The skin is constantly exposed to various internal and external forces resulting in different kinds of strains. Intermediate filaments are known to be essential for cell resistance to mechanical stress. In the epidermis, different keratins make up the intermediate filament network, according to the cell layer considered. The basal layer contains keratins 5 and 14, whereas the suprabasal layers contain keratins 1 and 10. On the other hand, the small heat shock protein HSP27 is known to protect the cytoskeletton (actin and intermediate filaments) against a large range of stresses. HSP27 can also be specifically involved in the reorganization of intermediate filament networks. In normal epidermis, HSP27 is produced in the suprabasal layers. Thus, we wondered if HSP27 could protect keratinocytes against mechanical stress by interacting with keratins. We analyzed the dynamics of HSP27 and intermediate filaments production and distribution in keratinocytes subjected to cyclic stretching. Stretching results in a rapid and transient reduction of the amount of HSP27 protein. Immunocytochemical analyses confirm this observation and show that HSP27 is progressively produced in groups of cells before getting back to a broad distribution. Interestingly, the distribution of basal keratins follows the same changes as HSP27, with a stricking colocalization of the signals. These results show that stretching alters the organization of keratin networks and suggest that HSP27 is involved in these modifications.

315

**P38 MAPK-dependent Shaping of the Keratin Cytoskeleton**

S. Wöll, R. Windoffer, R. E. Leube; Department of Anatomy and Cell Biology, Johannes Gutenberg University, Mainz, Germany

We recently observed that the tyrosine phosphatase inhibitor vanadate induces rapid and reversible reorganization of the keratin cytoskeleton. It was further noted that these changes were almost completely prevented by prior exposure to light of different wavelengths and, to a lesser degree, by pre-treatment with the p38 MAPK inhibitor SB203580. To further follow up on the latter observation, we examined the phosphorylation of a potential p38 MAPK target site in keratin 8. Less than 30 seconds after exposure to vanadate a strong increase in phosphorylation occurred in this site in the dark that was completely blocked in the light. Although p38 MAPK activation was only mildly affected in these situations as judged by its phosphorylation status, a significant recruitment of phosphorylated p38 MAPK to the keratin system and, especially, newly forming granular aggregates was evident within two minutes of vanadate exposure in the dark. Similar phenomena were noted in other situations of keratin filament restructuring. To directly assess the importance of p38 MAPK for the keratin system shRNA-encoding constructs were prepared. Transfection of these constructs into epithelial cells resulted in significant alterations of the intermediate filament cytoskeleton. Taken together, we propose that p38 MAPK regulates keratin filament formation, most likely by phosphorylation of specific sites.

316

**Cell Stress is a Key Factor in the Phenotypic Variation of the R416W GFAP Mutation Causing Alexanders Disease**

S. Wen,[1] M. Perng,[1] R. Li,[2] M. Brenner,[2] R. A. Quinlan[1]; [1]School of Biological Sciences, University of Durham, Durham, United Kingdom, [2]Department of Neurobiology and Civitan International Research Center, University of Alabama at Birmingham, Birmingham, AL

Alexander Disease (AD) is a fatal neurological disorder characterised by the presence of cytoplasmic inclusion called Rosenthal fibers, which contain astrocytic intermediate filament (IF) glial fibrillary acidic protein (GFAP). Many AD patients contain one of a series mutations in the GFAP gene. In this study, we present evidence to suggest that one of the mutation, R416W , in GFAP requires additional factors to precipitate AD. The reported cases for R416W show a wide range in disease severity and age of onset, suggesting that epigenetic and/or environmental factors could play key roles in disease progression . In vitro assembly studies showed that the mutation altered filament assembly, inducing the formation of short filament pieces that tend to laterally associate. Transient transfection studies revealed that the level of GFAP expression and the availability of a coassembly-competent endogenous network could influence the phenotypes observed, from the collapse of the whole IF network to the complete integration of the mutant protein. Doxycycline-inducible astrocyte cell lines expressing mutant and WT GFAP were established and confirmed that the R416W GFAP could incorporate into existing GFAP networks, without causing their collapse or altering their distribution. Only when these cells were exposed to oxidative or osmotic stresses were the detrimental effects of the R416W GFAP mutation apparent. These data suggest that this particular disease causing mutation requires either trauma or another stress to precipitate the disease, offering an explanation for the phenotypic variation for this mutation. Our data also establish that filament network disruption is not a necessary prerequisit to identifying the potential of disease causing mutations in IFs, but rather identify mutations where epigenetic factors are likely to have most influence on the appearance and progression of the disease.

317

**Steering Human Vimentin Unit-length Filament (ULF) Formation and Filament Elongation by Systematically Mutating its Coil 1A**

T. Wedig,[1] G. Padilla,[2] P. Burkhard,[2] R. Zimbelmann,[3] U. Aebi,[4] H. Herrmann[1]; [1]Molecular Genetics, German Cancer Research Center, Heidelberg, Germany, [2]The Institute of Materials Science, University of Connecticut, Storrs, CT, [3]Cell Biology, German Cancer Research Center,

Heidelberg, Germany, [4]M.E.Mueller Institute, University of Basel, Biozentrum, Basel, Switzerland

Intermediate filaments (IFs) of the vimentin/desmin-type associate massively from soluble tetrameric complexes into approximately 60 nm long full-width filaments, so-called ULFs, within one second after assembly has been started. We have recently shown that mutation Lys139 to Cys, the first amino acid of linker L1 of human vimentin, stalls assembly at the ULF-stage when carried out at 22°C, whereas at 37°C assembly proceeds normal (Mucke et al., 2004, JMB 340, 97-114). An even more drastic effect is observed upon mutation of Arg113 to Cys in the IF consensus motif NDR in coil 1A. This mutation causes the association of tetramers into distinct, approximately 30 nm-diameter globular particles resembling disordered ULFs (for the corresponding desmin mutation, see Haubold et al., 2003, Cell Motil Cytoskel 54, 105-121). In order to investigate if and how the strength of the inter-helical coiled-coil forming forces - i.e. as assessed by measuring the melting temperature of the corresponding peptides - is correlated with the filament assembly abilities of vimentin, we have systematically mutated a and d positions in coil 1A into hydrophobic amino acids and/or cysteines. Moreover, the cysteine mutants were further analyzed after being cross-linked in and renatured from 4 M urea. Interestingly, while the thus clipped dimers readily assemble into long, unaggregated filaments, their finer ultrastructure and filament width render them different from *bona fide* IFs. Last but not least, the assembly behavior and morphology of these various mutated proteins in vimentin-free cells is presented too.

318

**Mechanical Manipulation of Single IFs in vitro - Towards Understanding the Mechanical Role of IFs in vivo**

L. Kreplak,[1] N. Mücke,[2] H. Bär,[3] J. Leterrier,[4] H. Herrmann,[5] U. Aebi[1]; [1]M.E. Müller Institute, Biozentrum, University of Basel, Basel, Switzerland, [2]Division Biophysics of Macromolecules, German Cancer Research Center (DKFZ), Heidelberg, Germany, [3]Medizinische Universitätsklinik Heidelberg, Heidelberg, Germany, [4]Institut de physiologie et biologie cellulaires, Poitiers University, Poitiers, France, [5]Department of Molecular Genetics, German Cancer Research Center (DKFZ), Heidelberg, Germany

Intermediate filaments (IFs) fulfil basic mechanical function in cells and tissues. However, it is still ill defined how keratins, desmin or lamin "function" at the molecular level, respectively. Because of the discovery of dramatic phenotypes in patients presenting point mutations in genes coding for IFs protein such as desmin and keratins, a rational understanding of the mechanical function of IFs is highly needed. We will present findings concerning the mechanics of single IFs in vitro using a scanning force microscopy approach (SFM). The extensibility and toughness of IFs was studied by an online nano-manipulation approach. The SFM tip was used to move or stretch single IFs directly on the support to which they were adsorbed. By this method, IFs were stretched several fold and clear morphological changes were observed, especially a large reduction of the apparent diameter. These results are in good agreement with previous studies on the mechanical properties of macroscopic IF containing fibres such as Hagfish slime threads (Fudge et al. Biophysical Journal (2003), 85, 2015-2027). All in all, the available data support a mechanical shock absorber role for IFs in vivo.

319

**Imaging Native Intermediate Filaments Deposited on Different Solid Supports by Atomic Force Microscopy - Comparison With Simulated Images**

N. Mücke,[1] K. Klenin,[1] R. Kirmse,[1] L. Kreplak,[2] T. Wedig,[3] J. Langowski,[1] U. Aebi,[2] H. Herrmann[3]; [1]Biophysics of Macromolecules, German Cancer Research Center, Heidelberg, Germany, [2]Biozentrum, University of Basel, Basel, Switzerland, [3]Division of Cell Biology, German Cancer Research Center, Heidelberg, Germany

We have imaged by atomic force microscopy (AFM) intermediate filaments (IFs) and IF assembly intermediates after deposition onto different solid supports. AFM of the immobilized IFs and IF intermediates was performed in physiological buffer solution without drying, fixing or washing the samples. As expected, the morphology and biomechanical properties of the adsorbed IFs strongly correlated with the electrostatic properties of the support employed, such as, for example, freshly cleaved mica or hydrophilic glass (cf. Mücke et al. (2004) *J. Mol. Biol*., **335**: 1241-1250). In order to determine the biomechanical parameters of the filaments - for example, the persistence length as a measure of their flexural rigidity - from such AFM images, one has to take into consideration the mechanism governing the deposition processes that, in turn, dictates the filament-surface interactions. To more rationally understand this "capture" mechanism, we performed Brownian dynamics simulations of the stepwise adsorption of 3D polymer chains onto a solid support. Ultimately, these simulations which were animated in a time-lapse series, enabled us to mechanistically interpret the different steps of the filament deposition process as was observed by AFM.

320

**Characterization of Two Different Types of Human Desmin Filaments by Atomic Force Microscopy**

N. Mücke,[1] T. Wedig,[2] J. Langowski,[1] U. Aebi,[3] H. Herrmann[2]; [1]Biophysics of Macromolecules, German Cancer Research Center, Heidelberg, Germany, [2]Division of Cell Biologie, German Cancer Research Center, Heidelberg, Germany, [3]Biozentrum, University of Basel, Basel, Switzerland

We have investigated the properties of filaments assembled from human desmin under different ionic strength conditions (2mM sodium phosphate, pH 7.5, 20-100 mM KCl). Desmin filaments grew much faster than vimentin filaments in 100 mM KCl where huge networks formed within minutes. In 20 mM KCl, desmin assembly was much slower and network formation was suppressed. By atomic force microscopy (AFM) desmin filaments formed in 20 mM KCl exhibited morphological and biomechanical properties that were distinct from those obtained in 100 mM KCl. More specifically, in 20 mM KCl the filaments exhibited a height of 6 nm compared to 9 nm in 100 mM KCl, most likely indicating a decrease in the number of dimers per filament cross-section. Second, a significant decrease in the flexural rigidity of the mature desmin filaments was measured at the lower ionic strength. Third, the filaments exhibited a tendency to form 'closed rings' after several hours of incubation in 20 mM KCl, indicating that end-to-end fusion of the filaments had occurred. Last but not least, we document that the 6-nm high filaments that formed in 20 mM KCl were able to fuse end-on with thick filaments polymerized in 100 mM KCl.

**Mechanisms of Cardioprotection by Desmin Cytoskeleton: Targeting Permeability Transition Pores at Mitochondrial Contact Sites**

Y. Capetanaki,[1] K. Rapti,[1] E. Soumaka,[1] M. Mavroidis,[1] N. Weisleder[2]; [1]Cell Biology Division, Center of Basic Research, Foundation of

Biomedical Research, Academy of Athens, Athens, Greece, [2]Cell Biology, Baylor College of Medicine, Houston, TX
We have demonstrated that desmin, the muscle specific intermediate filament (IF) protein, is very important in muscle maintenance and its absence leads to muscle degeneration with extensive fibrosis and calcification, cardiomyopathy and heart failure. Human mutations in desmin or other cytoskeletal proteins, directly or indirectly associated to desmin network, are linked to development of similar defects and heart failure. Thus, it is impoprtant to understand the mechanisms by which disturbance in this cytoskeletal network leads to the onset and development of cardiomyocyte death. Our studies have demonstrated that the most prominent and earliest detected feature of the desmin null phenotype is defects in mitochondrial shape, number, integrity and function. We try to understand the mechanisms leading to these defects and the ways by which these mitochondrial abnormalities lead to cell death. Towards this goal, complementation genetics, atlas arrays and proteomic analyses were used and demonstrated that indeed mitochondrial abnormalities must be the major target and primary cause of the observed cardiomyopathy, most possibly as a consequence of alterations in the mitochondrial contact sites due to the absence of desmin. More specifically, among others, changes in proteins important for the permeability transition pore function, such as porin (VDAC) and its associated proteins hexokinase, creatine kinase and small heat shock proteins, have strongly suggested that this channel might be an important target. Indeed, our first success in ameliorating mitochondrial abnormalities, cardiomyocyte death, cardiomyopathy and heart failure, by overexpressing bcl2, an antiapoptotic protein located at the mitochondrial contact sites, known to regulate VDAC function, strongly supports our hypothesis. It further suggests that IFs might participate either in the correct targeting of proteins to these sites or their stabilization there thus potentially controlling mitochondrial membrane permeability and cell survival.

## Modeling Intermediate Filament Networks

S. Portet; Mathematics, University of Manitoba, Winnipeg, MB, Canada

Mathematical models can be helpful in the study of intermediate filament assembly and organization. We have proposed a model to study the dependence of the structural organization of these networks on the mechanical extracellular environment. The model phenomenologically describes the mechanical environment and its effects on the cell. The environment and the elastic properties of filaments jointly determine the structural organization of networks. Computational simulations provide three-dimensional architectures of the network for particular mechanical environments. As this model is very complex, we are developing simplified versions in order to be able to study the dynamics of the different states of intermediate filament material.

## Effect of Alexander Disease-causing Mutations on GFAP Filament Assembly and Network Organisation

M. Perng, S. Wen, T. Gibbon, R. Quinlan; School of Biological Sciences, University of Durham, Durham, United Kingdom

Alexander disease (AD) is a rare, but often fatal neurological disorder characterised by the abundant presence in astrocyte of protein aggregates containing the astrocytic intermediate filament (IF) protein glial fibrillary acidic protein (GFAP). Recently, de novo missense mutations in the GFAP have been reported to be associated with nearly all forms of this disease. In this study, we investigate the biological effects of several GFAP mutations on the in vitro assembly and intracellular distribution of IF networks in a range of cell lines with different IF expression profiles. These results were compared with those obtained previously for other GFAP mutations. GFAP mutations located within the rod domain had relatively minor effects on filament assembly and network formation. In vitro, GFAP with internal mutations are able to self-assemble into typical IFs. Although these GFAP mutants failed to form normal filament networks in IF-free cells, they incorporated into filamentous networks in cells expressing co-assembly partners, such as vimentin and GFAP. The most striking effects on IF assembly and network formation were observed with mutations at the highly conserved motifs, namely the LNDR and TYRKLEGGE motifs, at the start and the end of the central rod domain. These mutations perturb both filament assembly in vitro and network configuration in vivo. Similar effects were observed in mutations within the C-terminal tail domain, which affects both filament assembly in vitro and network formation when transiently expressed in cells. These data indicate that individual mutations distributed throughout the GFAP are not equal with the respect to their roles in filament assembly and network formation. These results have important implications for the wild variability in the age of onset and phenotypic severity of the AD.

323A

## KIF5A is Required for Both Anterograde and Retrograde Movement of Neurofilaments in Axons

A. Uchida, A. Brown; Center for Molecular Neurobiology, The Ohio State University, Columbus, OH

Neurofilaments are transported bidirectionally along axons in a rapid infrequent manner. The retrograde motor is dynein but the anterograde motor is unknown. Recently the Goldstein lab reported that targeted deletion of KIF5A in mice causes neurofilament accumulation in DRG cell bodies and a reduction in axonal caliber with no apparent effect on organelle transport, suggesting that KIF5A is an anterograde neurofilament motor. To test this hypothesis, we cultured neurons from wild type (WT) and KIF5A-/- mice. Both sympathetic (SCG) and sensory (DRG) KIF5A-/- neurons extended axons that contained neurofilaments. To examine neurofilament transport, we performed time-lapse fluorescence imaging on SCG neurons expressing GFP-tagged neurofilament protein. The frequency of both anterograde and retrograde neurofilament movement was reduced significantly compared to WT ($p<0.001$, K-S test; average reduction=75%). For those neurofilaments that moved, the average anterograde velocity (excluding pauses) was reduced significantly ($p=0.001$, K-S test; average reduction=52%) but the average retrograde velocity was not ($p=0.4$, K-S test). Immunostaining revealed apparently normal dynein/dynactin levels in KIF5A-/- axons and Western blotting revealed normal levels of dynein/dynactin and kinesin light chains in KIF5A-/- brain. Expression of full-length KIF5A in KIF5A-/- SCG neurons rescued the frequency of neurofilament movement in both directions and partially rescued the anterograde velocity. Expression of a “dominant negative” headless KIF5A in WT SCG neurons completely inhibited movement in both directions. Collectively these data indicate that (1) KIF5A is the principal but not exclusive anterograde motor for neurofilaments in SCG neurons, (2) proteins with homology to KIF5A, probably KIF5B and/or KIF5C, may also be capable of moving neurofilaments anterogradely, and (3) KIF5A is necessary for normal retrograde movement of neurofilaments, which suggests a direct or indirect interaction between the dynein and kinesin motors.

## Focal Adhesions (324-341)

324

### Focal Adhesion Protein and p130Cas Coordinately Regulate *Salmonella typhimurium* Invasion

J. Shi, J. E. Casanova; Cell Biology, University of Virginia, Charlottesville, VA

Cellular invasion by *Salmonella typhimurium*, a gram-negative bacterial pathogen colonizing intestinal epithelia, involves recruitment of focal adhesion proteins to the sites of infection. However, whether these focal adhesion proteins play a role in *Salmonella* entry remains largely undefined. Here, we demonstrate that focal adhesion kinase (FAK) and p130Cas localize to the sites of bacterial infection despite the fact that integrins are not engaged by *Salmonella.* Both FAK and Cas are required for *Salmonella* uptake as cells genetically deficient in either protein (FAK-/- or Cas-/-) exhibit a marked reduction in bacterial colonization, and reconstitution of these cells with wild-type proteins restores bacterial internalization. Surprisingly, bacterial internalization does not require FAK kinase activity, but does require its ability to interact with Cas. In agreement with this finding, *Salmonella* infection stimulates the formation of a complex containing FAK, Cas and paxillin. Moreover, infection of Cas-/- cells leads to formation of enlarged phagocytic structures containing aberrantly organized actin, suggesting that Cas is necessary for proper formation of the phagocytic apparatus. Together, these findings reveal a novel role for focal adhesion proteins in the invasion of host cells by *Salmonella.*

325

### Focal Adhesion Kinase and Src Phosphorylations in HGF-Induced Proliferation and Invasion of Human Cholangiocarcinoma Cell Line, HuCCA-1

V. Leardkamolkarn,[1] U. Pongchairerk,[1] J. Guan[2]; [1]Anatomy, Mahidol University, Bangkok, Thailand, [2]Molecular Medicine, Cornell University, Ithaca, NY

**Abstract** **AIM:** To study the role of FAK (focal adhesion kinase) and its association with Src in HGF induced cell signaling in cholangiocarcinoma progression. **METHODS:** Previously isolated HuCCA-1 cells were re-characterized by immuno-staining and RT-PCR assay for the expressions of cytokeratin19, HGF and c-met mRNA. Cultured HuCCA-1 cells were treated with HGF and determined for cell proliferation and invasion effects by MTT and invasion assays. Western blotting, Immunoprecipitation and Co-immunoprecipitation were also performed to study the phosphorylation and interaction of FAK and Src. A novel Src inhibitor (AZM555130) was applied in cultures to investigate the effects on FAK phosphorylation inhibition and on cell proliferation and invasion. **RESULTS:** HGF enhanced HuCCA-1 cell proliferation and invasion by mediate FAK and Src phosphorylations. FAK-Src interaction occurred in a time dependent manner where Src was proved to be an upstream signaling molecule to FAK. The inhibitor to Src decreased FAK phosphorylation level in correlation with the reduction of cell proliferation and invasion. **CONCLUSION:** FAK plays a significant role in signaling pathway of HGF responsive cell line derived from cholangiocarcinoma. Autophosphorylated Src, induced by HGF, mediates Src kinase activation which subsequently phosphorylates its substrate, FAK, and signals to cell proliferation and invasion. **Keywords:** Human cholangiocarcinoma; Hepatocyte growth factor; C-met; Focal adhesion kinase; Src

### Focal Adhesion Kinase Modulates Cell Adhesion Strengthening

K. E. Michael,[1] N. D. Gallant,[2] S. K. Hanks,[3] A. J. Garcia[1,2]; [1]Petit Institute for Bioengineering and Bioscience, Georgia Institute of Technology, Atlanta, GA, [2]Woodruff School of Mechanical Engineering, Georgia Institute of Technology, Atlanta, GA, [3]Department of Cell Biology, Vanderbilt University School of Medicine, Nashville, TN

Integrin-mediated cell adhesion to extracellular matrices (ECM) plays critical roles in numerous physiological and pathological processes. Matrix-bound integrins associate with the cytoskeleton and cluster to form focal adhesions (FA), which link the cytoskeleton to ECM and trigger signaling pathways. Focal adhesion kinase (FAK) is a non-receptor tyrosine kinase with multiple targets that is essential to development and regulates FA turnover, cell spreading, and migration. We analyzed the contributions of FAK to adhesion strengthening using FAK-/- cells engineered to re-express WTFAK and FAK mutants, directed at the Y397-autophosphorylation and Y576/577-catalytic sites, under a tetracycline-inducible promoter and a hydrodynamic adhesion strength assay. Micropatterned substrates were used to provide controlled adhesive areas and isolate FA assembly from gross changes in cell shape. Adhesion strength over time was characterized as a logarithmic rise to maximum with parameters of steady-state adhesion strength and strengthening rate (inverse time constant). Compared to FAK-/- cells, WTFAK re-expression significantly reduced steady-state adhesion strength (29%) and increased strengthening rate (5-fold) whereas expression of Y397F-FAK decreased strengthening rate (52%) and Y576/577F-FAK revealed no differences from FAK-/- cells. Quantification of the number of bound alpha5 or alphaV integrins on fibronectin surfaces at steady-state revealed no differences for all cell types, demonstrating that the differences in steady-state adhesion strength were not due to differences in integrin binding. This modulation in adhesion strength can be explained by differences in the localization and distribution of FA in the adhesive area. Immunofluorescence staining at steady-state showed less FA-containing area occupied by vinculin for cells expressing WTFAK (44%); however, no differences were detected for talin. No differences in steady-state vinculin localization were observed for cells expressing Y397F-FAK or Y576/577-FAK. These results indicate that FAK is directing composition and position of FA molecules, preferentially vinculin turnover, thereby reducing steady-state adhesion strength.

327

### Supervillin Modulates Cell Adhesion through a Binding Site for the Focal Adhesion Protein, TRIP6/ZRP-1

N. Takizawa,[1] T. C. Smith,[1] T. Nebl,[1] J. L. Crowley,[1] L. M. Lifshitz,[2] L. M. Hoffman,[3] M. C. Beckerle,[3] E. J. Luna[1]; [1]Department of Cell Biology, University of Massachusetts Medical School, Worcester, MA, [2]Department of Physiology, University of Massachusetts Medical School, Worcester, MA, [3]Huntsman Cancer Institute, University of Utah, Salt Lake City, UT

Cell-substrate adhesion is regulated at focal adhesions (FA) on the plasma membrane. We report here that supervillin (SV)-a peripheral membrane protein that also binds myosin II, F-actin, and calponin-inversely regulates cell adhesion, vinculin-associated FA, and stress fiber formation. In COS-7 cells, a 90% RNAi-mediated knockdown of SV increased by 180% cell adherence to fibronectin in a centrifugation assay (300 x g, 5 min). A FA regulatory sequence within SV amino acids 342-571 (SV342-571) dramatically decreased FA and stress fibers when expressed in COS-7

cells. SV342-571 also decreased the ability of CV-1 cells to deform flexible substrates, a measure of FA and stress fiber function. Potential FA-associated targets were identified by yeast two hybrid analysis and tested for associations with SV and SV fragments in immunofluorescence co-localizations and GST protein pull-downs. We found specific interactions between SV342-571 and two of the three members of the zyxin protein family: SV342-571 binds to the LIM domains of thyroid receptor-interacting protein 6 (TRIP6)/zyxin-related protein 1 (ZRP-1) and lipoma-preferred protein (LPP), but not to the LIM domains of zyxin itself. SV and full-length TRIP6 co-localized when overexpressed in COS-7 cells, and endogenous SV and TRIP6 co-localized within the large FA of A7r5 smooth muscle cells. SV knockdown reduced co-localization of TRIP6, but not zyxin, with vinculin at FA. Overexpression of TRIP6 LIM domains, but not zyxin LIM domains, partially rescued the disruptive effects of SV, SV1-830 and SV342-571 on stress fiber formation. Full-length TRIP6 partially reversed the stress fiber-disrupting effect of full-length SV and SV1-830, but not that of SV342-571. Our results suggest that SV342-571 may disrupt FA by recruiting TRIP6 to FA and that additional SV sequences may modulate TRIP6 function. Supported by NIH grants GM33048 and GM50877.

**CaMK-II Activation Promotes Detachment from the Extracellular Matrix**

C. A. Easley,[1] M. O. Faison,[2] R. M. Tombes[3]; [1]Biochemistry, Virginia Commonwealth University School of Medicine, Richmond, VA, [2]Biology, Virginia State University, Petersburg, VA, [3]Biology, Virginia Commonwealth University, Richmond, VA

Fibronectin, a multiadhesive glycoprotein, enables cell adhesion to the extracellular matrix through the β1 subunit of integrin receptors in NIH 3T3 cells. Through interaction with its receptor, fibronectin is known to induce a localized increase in cytosolic $Ca^{2+}$ levels. In this study we first sought to determine whether CaMK-II was the target of the $Ca^{2+}$ flux upon fibronectin binding to β1 integrin. Here, we show that plating cells on fibronectin increases CaMK-II activity in a dose-dependent manner. We also show that disruption of the integrin β1-fibronectin interaction via mechanical rotation, the CD29 integrin β1 antibody, and RGD peptide (GRGDNP) significantly reduces CaMK-II activity. These data suggest that CaMK-II is a target of the $Ca^{2+}$ flux induced by the β1 integrin-fibronectin interaction. We show that ectopically-expressed GFP-linked CaMK-II is enriched at the leading and trailing edges of motile cells. Transfection with constitutively active CaMK-II induces a rounded morphology of cells when subsequently plated on fibronectin. Also, we show that an inhibition of CaMK-II by KN-93 and the myristoylated autoinhibitory peptide (mAIP) causes cells to attach to fibronectin-coated dishes more rapidly than untreated cells, but these treated cells show no dynamic motility after adhering. Taken together, these data suggest that upon attachment of cells to fibronectin through β1 integrin, a $Ca^{2+}$ flux activates CaMK-II, and activated CaMK-II promotes detachment from the extracellular matrix at the leading and trailing edges of NIH 3T3 cells.

329

**Rho-small GTPase Regulates Cell Adhesion Strengthening via Modulation of Focal Adhesions and FAK**

H. Shin,[1] H. Radhakrishna,[2] A. J. Garcia[1]; [1]Mechanical Engineering, Georgia Institute of Technology, Atlanta, GA, [2]Biology, Georgia Institute of Technology, Atlanta, GA

Cell adhesion represents a coordinated process of integrin binding to extracellular matrix components, recruitment of cytosolic adhesive molecules, and formation of focal adhesions. The dynamic remodeling of focal adhesions correlates with many cellular processes such as cell cytokinesis, differentiation, and motility. Although it is well established that members of the Rho family of small GTPase play central roles in cytoskeletal assembly and architecture, little is known about how Rho GTPase regulates the adhesion strengthening processes. In this study, we have tested the hypothesis that Rho GTPase modulates cell adhesion strengthening via reorganization of focal adhesions. We have previously demonstrated that focal adhesion composition is regulated by actin-myosin contractility, thereby modulating cell adhesion strengthening. To test the effect of Rho GTPase in cell adhesion, we measured the adhesion strength of NIH3T3 fibroblasts subjected to Rho activation via lysophosphatidic acid (LPA). The focal adhesion size and position were controlled by plating cells on fibronectin-coated surfaces micropatterned via micro-contact printing of self-assembled monolayers of alkanethiols. Treatment of fibroblasts with LPA increased cell adhesion strength in a dose dependent manner. At the highest concentration of LPA, cell adhesion strength increased 45% relative to serum-starved conditions. Immunofluorescence staining for vinculin and talin revealed that LPA stimulate assembly of focal adhesion within the micropatterned substrate. These results suggest that Rho GTPase activation by LPA is involved in regulation of cell adhesion strengthening through focal adhesion assembly.

330

**Rac1 Activation and Translocation to Matrix Adhesion Sites Is Facilitated by FAK**

F. Chang, C. Lemmon, D. Horvitz, L. Romer; Anesthesiology and Critical Care Medicine, Johns Hopkins University School of Medicine, Baltimore, MD

FAK, a cytoplasmic protein tyrosine kinase, is activated and localized to focal adhesions upon cell attachment to extracellular matrix. The observations that FAK null cells spread poorly, and exhibit different focal adhesion arrays suggest that FAK may be involved in focal adhesion turnover and the promotion of cell spreading. Rac1 is a member of the Rho-family GTPases that promotes extension of the leading edge, membrane ruffling, and cell spreading. We investigated Rac1 activation and subcellular location in FAK null and FAK re-expressing MEF. FAK re-expressers had a more robust pattern of Rac1 activation following cell adhesion to fibronectin than the FAK null cells. Translocation of Rac1 to the tips of focal adhesions was observed in FAK re-expressers, but rarely in FAK null cells. Experiments with constitutively active Rac61L and dominant negative Rac17N demonstrated that the activation state of Rac1 determines its localization to focal adhesions in either the presence or the absence of FAK. βPIX is a Rac/Cdc42-specific GEF that activates Rac1. Our results showed that like Rac1, βPIX was also recruited to focal adhesion sites upon attachment to fibronectin and may be responsible for the activation of Rac1 and its recruitment to focal adhesion sites. FAK appears to have a role in Rac1 activation and focal adhesion translocation that may be mediated by βPIX.

331

**Visualizing Dynamic Structures in Migrating F9-Derived Parietal Endoderm**

K. A. LaMonica,[1] T. Hong,[1] J. Mulrooney,[2] L. B. Grabel[1]; [1]Department of Biology, Wesleyan University, Middletown, CT, [2]Department of Biomolecular Sciences, Central Connecticut State University, New Britain, CT

Visualizing Dynamic Structures in Migrating F9-Derived Parietal Endoderm Control of cell migration is essential for proper development.

Unregulated migration can lead to tumor cell metastasis. F9 teratocarcinoma cells form embryoid bodies consisting of an inner core of undifferentiated stem cells surrounded by an outer layer of visceral endoderm. When embryoid bodies are plated on laminin substrates, parietal endoderm migrates away from the embryoid body as a sheet of cells, and this outgrowth is reminiscent of parietal endoderm migration in vivo. Parietal endoderm outgrowth contains leading edge structures such as lamellipodia and filopodia, and adhesion structures such as focal adhesions and focal complexes. Our previous data has shown that perturbation of the Rho signaling pathway at the level of its downstream effector ROCK and over-expression of p190 Rho GAP lead to increased parietal endoderm migration and formation of lamellipodia, and a decrease in focal adhesions. On the other hand, inhibition of the ERK signaling pathway, at the level of MEK and Raf, leads to decreased migration and an abundance of stable focal adhesions. These data suggest that Rho provides the brakes and ERK provides the wheels during parietal endoderm migration. Using live cell imaging techniques, under control conditions, we observe abundant filopodia and lamellipodia formation in the outer ring cells of the outgrowth. Behind the outer edge, cells migrate as a sheet, maintaining close association with each other. We are now observing how migratory and adhesion structures are altered when ROCK or ERK are inhibited. We are also investigating the roles of Rac in directing lamellipodia extension at the leading edge of the outgrowth.

332

**Differential Phosphorylation of Cortactin Regulates Lamellipod Extension Through Alterations in Adhesion Plaque Dynamics**

A. E. Kruchten, E. W. Krueger, M. A. McNiven; Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN

Cortactin is an actin binding protein upregulated in several cancers and a substrate of the tyrosine kinase Src. ERK and Src phosphorylation of cortactin has been implicated in positive and negative effects on actin polymerization *in vitro*, respectively. Surprisingly, Src phosphorylation of cortactin has been shown to promote actin dependent cell migration and enhance the metastatic capacity of cells *in vivo*. The GOAL OF THIS STUDY was to directly test the roles of cortactin phosphorylation on actin assembly and motility in living fibroblasts and metastatic human pancreatic cells. Several different phospho-forms of cortactin altered at key tyrosines or serines were expressed and changes in lamellipod extension, focal adhesions, and actin assembly quantified. Expression of a phospho-mutant of cortactin mimicking Src phosphorylation (Y384/429/445E) resulted in a dramatic extension of lamellipodia in the absence of stimulation, while the phospho-blocking mutant (Y384/429/445F) inhibited lamellipodia formation. Because dendritic actin polymerization supports membrane extension and migration, we next examined this process *in vivo* using an “actin comet” formation assay. A cortactin mutant mimicking ERK-mediated serine phosphorylation (S368/381D) resulted in a two-fold increase in comet formation while the tyrosine mutants had no effect To test how tyrosine phosphorylation promotes lamellipodial extension while inhibiting actin polymerization, the effects of cortactin mutants on focal adhesions and cell spreading were examined. Interestingly, the cells expressing cortactin Y384/429/445E exhibited faster spreading on fibronectin resulting in larger cells with more numerous focal adhesions and decreased cortactin association. From these observations, we predict that tyrosine phosphorylation plays a role in the turnover of focal adhesions and subsequent cell motility and metastasis while serine phosphorylation promotes actin polymerization. These findings provide some of the first insights into a role for differential cortactin regulation of focal contact function and cell adhesion.

333

**Focal Adhesion Kinase Couples Lpa Signaling to Focal Adhesion Retrograde Flow and Subsequent Changes in Cell Shape**

M. Iwanicki, T. Vomastek, R. Tilghman, K. Martin, J. T. Parsons; Microbiology, University of Virginia, Charlottesville, VA

The protein tyrosine kinase, Focal Adhesion Kinase (FAK) is an essential molecule in mediating beta1-dependent integrin signaling. Upon integrin engagement FAK becomes activated as evidenced by phosphorylation of tyrosine 397. FAK also becomes activated in response to growth factors such as Lysophosphatidic Acid (LPA), Thrombospondin, Bombasin and Epidermal Growth Factor. Activation of FAK initiates downstream signaling that has been implicated in regulation of cell migration and survival. We have utilized siRNAs for FAK to attenuate FAK levels in Rat-2 fibroblasts and have examined the role of FAK in LPA induced cell shape and changes in focal adhesion dynamics. Rat -2 fibroblasts with reduced FAK expression become elongated, exhibiting long axon like extensions. These extensions are rich in polymerized actin and microtubules. Attenuation of FAK expression in Rat-2 fibroblasts results in decreased responsiveness to LPA stimulation manifested in the inhibition of activation of the ERK pathway and PI3 kinase pathways. In addition, LPA stimulation of control siRNA cells but not FAK siRNA cells resulted in changes of ERM proteins phosphorylation suggesting that FAK is important in ERM mediated cell shape changes (*Lamb R.F , Current Biology 1997, 7: 682-688*). Inhibition of ROCK but not MEK, PI3K or MLCK in Rat 2 fibroblasts resulted in the characteristic elongated cell morphology, suggesting that ROCK is a component of FAK signaling. Finally, LPA stimulation of control siRNA but not FAK siRNA Rat 2 cells resulted in focal adhesion retrograde flow. Treatment of control siRNA Rat 2 cells with ROCK inhibitor abrogated retrograde flow of focal adhesions. These data strongly point to a model in which FAK couples LPA/ROCK signaling to the dynamic regulation of focal adhesions and subsequent changes in cell shape.

334

**Elucidating the Role of Myosin II Contraction in Adhesion Protein Dynamics and Maturation**

A. S. Kirby,[1,2] Y. Zilberman,[1,3] D. B. Weibel,[1,4] L. C. Kapitein,[1,5] C. Waterman-Storer[1,6]; [1]Physiology Course 2005, Marine Biological Laboratory, Woods Hole, MA, [2]Cell Biology, Duke University, Durham, NC, [3]Molecular Cell Biology, Weizmann Institute of Science, Rehovot, Israel, [4]Chemistry and Chemical Biology, Harvard University, Cambridge, MA, [5]Physics and Astronomy Laser Center, Vrije University, Amsterdam, The Netherlands, [6]Cell Biology, Scripps Research Institute, La Jolla, CA

Cells move by coupling forces generated in the actin cytoskeleton to the extracellular matrix via trans-membrane focal adhesions. RhoGTPase-regulated myosinII contraction of the cytoskeleton linked to adhesion induces integrin clustering and focal adhesion “maturation.” We hypothesize that tension-induced maturation of focal adhesions results in changes in protein composition and dynamics that may influence adhesion morphology, strength, and signaling. We first aimed to elucidate the relationship between contractility, maturation and protein binding/dissociation at focal adhesions. We performed FRAP of GFP-conjugated integinα5, FAK, paxillin, zyxin, talin, and vinculin expressed in mouse embryo fibroblasts. Protein dynamics fell into two categories, those with low fluorescence-recovery halftimes (t1/2) (<25s; talin, paxillin FAK and zyxin), and those more stably bound in adhesion sites (integrinα5, t1/2~100s; vinculin, t1/2~250s). Cells were treated with myosinII inhibitors to reduce contractility or transfected with activated Rac1 to induce immature focal complexes, and FRAP was performed on integrinα5, talin, and vinculin.

Talin and integrin dynamics were relatively insensitive to these treatments, while t1/2 of GFP-vinculin was greatly reduced by both activated Rac1 (~80s) and myosinII inhibition (<50s). We next sought to determine how induction of myosinII contraction promotes organization of actin bundles and maturation of adhesions. Cells co-expressing cherry-actin and GFP-paxillin were treated with myosin inhibitors to disassemble focal adhesions. Contraction was induced by drug washout and cells were analyzed by time-lapse fluorescence microscopy. During contraction, no de-novo adhesion formation was seen, rather focal complexes matured into focal adhesions by fusion of small preexisting clusters that increased GFP-paxillin fluorescence over time. Nascent actin bundles appeared to grow from fusing focal complexes, as opposed to being recruited from preexisting f-actin. These results indicate that myosinII contraction promotes maturation of adhesions by induction of actin filament growth and tight vinculin binding.

335

**Dissect the Relationship among of Focal Adhesions, Traction Forces, and Extracellular Matrix Organization**

W. Guo, Y. Wang; Physiology, UMASS Medical School, Worcester, MA

Migration of adherent cells involves the assembly-disassembly of focal adhesions, the exertion of traction forces, and the organization of the extracellular matrix (ECM). While previous studies have demonstrated a close relationship between the formation of nascent focal adhesions and the generation of strong traction forces at the leading edge, the function of traction forces remains unclear. In addition, it is puzzling that strong traction forces disappear underneath most focal adhesions as they mature, without concurrent movement or dissociation of focal adhesions from the ECM. To address these questions, we have plated 3T3 fibroblasts on flexible polyacrylamide substrates embedded with fluorescent microbeads and coated with fluorescent collagen or fibronectin. In addition, cells were transfected with GFP proteins to label focal adhesions. Simultaneous imaging of beads, focal adhesions, and the ECM allowed us to determine the relationship among substrate deformation, ECM organization, and focal adhesion assembly and disassembly. Our results suggest that the exertion of traction forces is coupled to the movement and organization of the underlying ECM. Therefore energy associated with traction forces may be used for the organization of ECM structures, which may in turn coordinate the migration of a population of cells during tissue formation and wound repair.

336

**The Role of Git1 Tyrosine Phosphorylation in Cell Spreading**

E. J. Kelly, J. E. Casanova; Dept. of Cell Biology, University of Virginia, Charlottesville, VA

Git1 is a GAP for ARF family GTPases that localizes to focal adhesions, the plasma membrane and cytosolic sites. In addition to its role as an Arf GAP, GIT1 also serves as a scaffolding protein, interacting with the Rac-GEF Pix through a central domain and the focal adhesion component paxillin through its C-terminus. The Git1/PIX complex mediates delivery of the p21 activated kinase, Pak to focal adhesions and the plasma membrane where it regulates both actin cytoskeleton and focal adhesion dynamics. Git1 becomes phosphorylated on multiple tyrosines in response to integrin ligation, but the role of these modifications in Git1 function is not known. We have identified four tyrosine residues (Y293, Y392, Y519 and Y607) whose mutation to phenylalanine alters the level of GIT1 phosphorylation. Mutation of Y392, Y519 or Y607 reduces the overall GIT1 phosphotyrosine level under normal growth conditions. Intriguingly, mutation of the fourth site, Y293, not only does not diminish phosphorylation, it actually leads to increased overall phosphorylation. All four mutants localize normally to focal adhesions, indicating that phosphorylation does not regulate focal adhesion targeting. To test the role of these phosphorylation events in cell behavior we examined their effects in a spreading assay in which cells were plated onto fibronectin. Surprisingly, we found that neither wild-type nor a catalytically inactive mutant of GIT1 impairs spreading, suggesting that GAP activity is not important in this process. Similarly, mutation of either Y392, Y519 or Y607 has no effect. In contrast, mutation of Y293 significantly slows spreading. Interestingly, Y293 lies within the binding site for PIX and we are currently working to determine if phosphorylation regulates the interaction with PIX.

337

**Erk1/2-Dependent Caldesmon Phosphorylation Regulates Podosome Turnover in A7r5 Smooth Muscle Cells**

Z. Gu, C. Hai; Molecular Pharmacology, Physiology & Biotechnology, Brown University, Providence, RI

Podosomes are focal adhesion-like cytoskeletal structures associated with the release of metalloproteases and degradation of extracellular matrix during cell invasion. PKC activation by phorbol dibutyrate (PDBu) has been shown to remodel actin stress fibers into F-actin-enriched podosome columns in A7r5 vascular smooth muscle cells, but the underlying signaling mechanism is not fully understood. Caldesmon is an actin-binding protein that stabilizes actin filaments against the action of actin-severing proteins in vitro. Furthermore, the MEK/Erk/Caldesmon phosphorylation cascade is an important mechanism of PKC-mediated contraction of smooth muscle cells. In this study, we tested the hypothesis that MEK1/2 and Erk1/2-dependent caldesmon phosphorylation regulates PKC-mediated podosome formation in A7r5 smooth muscle cells. We found that PDBu stimulated the phosphorylation of Erk1/2 and caldesmon by 15- and 20-fold, respectively. Immunofluorescence microscopy with Z-sectioning of PDBu-stimulated cells indicated colocalization of phospho-MEK1/2, phospho-Erk1/2, phospho-caldesmon and caldesmon at the ring of podosome columns. The MEK1/2 inhibitor, U0126 completely abolished PDBu-stimulated Erk and caldesmon phosphorylation. U0126-treated cells were still able to form podosomes associated with diminished levels of phospho-MEK1/2, phospho-Erk1/2 and phospho-caldesmon. However, the rate of podosome formation was significantly attenuated in U0126-treated cells. Overexpression of caldesmon by 180% (relative to β-actin) using caldesmon-GFP transfection induced the formation of podosome with caldesmon enriched in the core. Live-imaging of caldesmon-GFP dynamics during PDBu-induced podosome formation in A7r5 cells indicated a long lag time before the formation of podosomes and a slower turnover rate of podosomes. siRNA-knockdown of caldesmon expression by 70% induced the loss of some central stress fibers in A7r5 cells, however podosomes could still form in response to PDBu treatment. These results suggest that caldesmon is a regulator of podosome turnover rather than an essential structural component of podosomes in A7r5 smooth muscle cells.

**Tes is a Negative Regulator of Mena**

B. Boeda,[1] D. Briggs,[2] B. Garvalov,[1] N. McDonald,[2] M. Way[1]; [1]Cell Motility Laboratory, Cancer Research UK, London, United Kingdom, [2]Structural Biology Laboratory, Cancer Research UK, London, United Kingdom

It is now widely accepted that Ena/VASP family members are key players in regulating actin filament assembly during cell migration in a variety of different organisms. Studies from many groups have shown that the cellular localization of Ena/VASP family members is dependent on the association of their EVH1 domains with F/LPPPP motifs in binding partners such as zyxin, vinculin or lamellipodin. We now report that Tes, a LIM domain-containing protein, that is localised to focal adhesions interacts directly with the EVH1 domain of Mena. Surprisingly, this binding does not involve the canonical "FPPPP" sequence, but the LIM3 domain of Tes. We have solved the structure of the LIM3:EVH1 complex to obtain insights into this novel interaction. The crystal structure reveals that the LIM3 domain of Tes occludes the FPPPP binding site of the EVH1 domain of Mena. This suggests that the LIM3 domain of Tes may modulate the binding between the EVH1 domain of Mena and its FPPPP motif-containing partners. We present a variety of in vivo and in vitro evidence to support this hypothesis. In addition, the affinity of the Tes LIM3 domain for the EVH1 domain of VASP was drastically lower than that for Mena, suggesting that Tes may specifically regulate Mena but not VASP.

**Dominant-negative Alpha-actinin Disrupts Focal Adhesion Organization and Sensitizes Osteoblasts to Tumor Necrosis Factor-alpha-induced Apoptosis**

J. W. Triplett, F. M. Pavalko; Cellular and Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN

Maintenance of bone structural integrity is thought to depend greatly on the rate of apoptosis of bone-forming osteoblasts. Substrate adhesion is thought to be an important regulator of apoptosis, since a lack of adhesion results in anoikis. Focal adhesions are sites of cell attachment to, and signaling between, the substrate in osteoblasts. We hypothesize that α-actinin is positioned to play an important role in both focal adhesion organization and signaling, since it can interact with both structural and signaling components within focal adhesions. To test this, we over-expressed a dominant-negative form of α-actinin (ROD-GFP) that displaces endogenous α-actinin from focal adhesions, thus preventing the recruitment of actin to focal adhesions. Immunofluorescence and morphometric analysis of focal adhesions in MC3T3-E1 osteoblasts revealed that ROD-GFP expression caused a 40% reduction in focal adhesion area and long-axis length. To investigate the role of α-actinin in apoptosis, UMR106 osteosarcoma cells expressing ROD-GFP or a control GFP were treated with tumor necrosis factor-α (TNF-α), in the presence of cycloheximide, for a period of four hours. Preliminary experiments indicate that ROD-GFP expression alone does not induce apoptosis, but sensitizes cells to the apoptotic effects of TNF-α. The apoptotic markers histone 2A.X phosphorylation, caspase-3 cleavage, and poly-ADP-ribose polymerase cleavage were significantly increased in ROD-GFP expressing cells treated with TNF-α compared to GFP-expressing controls. To investigate the mechanism underlying this phenomenon, we assessed the ability of TNF-α to induce the known survival signal of nuclear factor-kappa B (NF-κB) nuclear translocation. By immunofluorescence, TNF-α-induced NF-κB nuclear translocation was inhibited in cells expressing ROD-GFP compared to controls. These data suggest that α-actinin may normally play a role in TNF-α induced signaling by promoting survival signals through the TNF receptor, either directly or through focal adhesions.

**Structure of the Alpha-Actinin-Vinculin Head Domain Complex Determined by Cryo-Electron Microscopy**

K. A. Taylor,[1] D. F. Kelly,[1] D. W. Taylor,[1] C. Bakolitsa,[2] A. Bobkov,[2] R. C. Liddington[2]; [1]Institute of Molecular Biophysics, Florida State University, Tallahassee, FL, [2]Dept. of Cell Adhesion and Extracellular Marix Biology, The Burnham Institute, La Jolla, CA

We have determined the vinculin binding site on α-actinin using cryoelectron microscopy of 2-D arrays formed on phospholipid monolayers doped with a nickel chelating lipid. Chicken smooth muscle α-actinin cocrystallized with HIS-tagged β1-integrin cytoplasmic tail and a vinculin fragment containing residues 1-258 (VD1). VD1 occupied a single site on α-actinin with 60-70% occupancy in a difference 3-D map relative to α-actinin alone. In these arrays, the two ends of α-actinin, each containing an actin binding and calmodulin-like domain, are held in distinctly different environments. The VD1 difference density has a shape consistent with its atomic structure, namely a pair of four helix bundles. The atomic model of the complex juxtaposes the α-actinin binding site on VD1 with the N-terminal lobe of the α-actinin calmodulin-like domain. These results establish this methodology for determining the structure of weakly interacting species in a membrane-like environment. Differential Scanning Calorimetry (DSC) confirms that the interaction between full-length α-actinin and the vinculin head domain (vinculin domains 1-3, VD1-3) is specific but weak. DSC also shows that the interaction between α-actinin and VD1-3 is significantly stronger when α-actinin is truncated at the N-terminus to remove the actin-binding domains. We propose that combinatorial interactions, such as α-actinin binding to the β-1 integrin tail allowing for stronger binding to VD1, regulate these binding events such that they only occur at prescribed sites in the cell such as focal adhesions.

**Generation and Characterization of Talin2 Mutant Mice**

N. Chen, Y. Liao, S. Lo; Center for Tissue Regeneration and Repair, University of California-Davis, Sacramento, CA

Talin is a large focal adhesion component that interacts with multiple molecules, such as integrins, focal adhesion kinase (Fak), vinculin, layilin and actin. A close related member, talin2, has been identified. Although talin2 is highly homologous to talin, many of its potential binding activities and physiological roles remain to be established. Talin1 knockout in mice leads to embryonic lethality due to impaired cell migration at the gastrulation stage. Here, we reported the characterization of mice carrying a beta-galactosidase insertion at talin2 gene, the distribution of talin2 in various tissues, and the identification of a testis splice form of talin2. Using a talin2 gene-trapped embryonic stem cell clone, we have developed a talin2 mutant mouse line that expresses the talin2 fused with beta-galactosidase. Crossing between heterozygous mice produced pups with expected Mendelian distribution of genotype ratio, indicating that this talin2 mutant did not lead to embryonic lethality. Using the RT-PCR and Northern blot analysis, we confirmed the gene-trap insertion has disrupted talin2 transcripts. In the testis, talin2 expresses as a shorter form with a unique 30 residues at N-terminus linking to a common C-terminus of the long form. However, it did not seem to affect the morphology of testis or reproduction of male mice. In fact, male and female mutant mice are fertile. Utilizing the expression of talin2/ beta-galactosidase fusion protein, we have examined the distribution of talin2 in tissues by X-gal staining. In contrast to talin1, talin2 expression is more restricted in tissues and cell types. Interestingly, most of the staining was concentrated on the basement membrane of the cells, suggesting that talin2, like talin1, was localized to the cell-matrix junctions. These data demonstrate the expression patterns of talin2.

## Cell-Cell Adherens Junctions (342-357)

342

### Turnover Dynamics of P120-catenin in Adherens Junctions : A Quantitative Analysis Using Fast 3D Imaging 0f FRAP

P. Kaiser,[1] C. Gueudry,[1] J. Sibarita,[2] A. Bershadsky,[3] F. Amblard[1]; [1]Physics dept, Curie Institute, Paris, France, [2]Biology dept, Curie Institute, Paris, France, [3]Dept Molecular Cell Biology, Weizmann Institute of Sciences, Rehovot, Israel

Adherens junctions (AJs) are complex molecular assemblies, based on cadherin transmembrane receptors, that perform adhesive interactions between contacting cells. AJs are thought to have some degree of plasticity, but their dynamic properties are poorly known. In particular, the molecular turnover rates of AJ components have not been assessed. p120-catenin interacts with the juxta-membranal cytoplasmic site of cadherin, and is required for AJ stability. We studied the turnover of p120-GFP in MCF-7 epithelial cells, using a novel instrument that employs fast 3D imaging to measure fluorescence recovery after laser mediated photobleaching. This enabled us generate a rapid sequence : (i) pre-bleach 2D-3D imaging, (ii) photobleaching user-defined target (spot, lines, polygonal regions) using fast moving mirors, and (iii) immediate imaging of the recovery in 2D-3D mode. The experimental parameters under control are : laser bleaching pulse power and duration, imaging rate. AJ were typically photobleached during 50-100 ms, and recovery was imaged with a 100 ms time resolution. FRAP on AJ depends on local, cytosolic p120 diffusion and on its dissociation rate from AJ. These two kinetic components were resolved by assessing the diffusion coefficient of p120 away from AJs, and then subtracting the computed diffusive component from the AJ recovery. Cytosolic diffusion coefficient was assessed at several points from the recovery of the 2D radial concentration profile. This procedure is robust to image noise and to irregular cell geometry. It yields typical diffusion coefficients of 10 micron^2/s. Recovery at AJs, once corrected for their diffusive component, led to a typical residence time of 10 seconds. Although this time might depend on p120 the expression level, it is much shorter than the 2 minutes time measured for ezrin at the epithelial apex.

### The Armadillo Protein Plakophilin 2 is Required for Assembly of the Intermediate Filament-Binding Protein Desmoplakin into Desmosomes

A. E. Bass, L. M. Godsel, E. V. Amargo, K. J. Green; Pathology, Northwestern University Feinberg School of Medicine, Chicago, IL

Plakophilin 2 (Pkp2), a member of the p120-subfamily of armadillo repeat proteins, is localized in the cytoplasmic plaque of desmosomes where it partners with a range of desmosomal proteins, including desmoplakin (DP). While ectopic overexpression of Pkp2 has been shown to enhance DP's recruitment to cell-cell borders, its specific role in desmosome assembly is unknown. Using a combination of fixed and live cell imaging and RNAi-mediated knockdown, we examined Pkp2's role in this process. Within minutes following cell-cell contact, intermediate filament-associated, DP-rich particles appeared in the cytoplasm, and subsequently were translocated to cell-cell borders where they were incorporated into nascent desmosomes. Confocal analysis of cells fixed over time following calcium-induced cell-cell contact revealed that Pkp2, but not desmosomal cadherins or the armadillo proteins plakoglobin or Pkp3, selectively co-distributed with DP particles. DP-GFP-expressing keratinocytes were imaged live and then fixed and stained to identify proteins that co-localize with assembly-competent particles. 100% of DP-GFP particles that coalesced and moved toward cell-cell contacts contained Pkp2, but none contained desmocollin or Pkp3. While some DP-GFP particles contained plakoglobin, translocation was not dependent on its presence. To directly test Pkp2's role in assembly, we used siRNA to reduce Pkp2 to <10% of control levels. Loss of Pkp2 inhibited DP particle formation and localization at cell-cell borders, whereas the distribution of other desmosomal and adherens junction proteins was unaffected. Pkp2 was also observed to co-localize with microfilaments, and actin but not microtubule perturbation impaired DP-precursor trafficking. These results suggest that junctional plaque precursor assembly and accumulation at nascent desmosomes requires Pkp2, and raises the possibility that Pkp2 might facilitate precursor translocation through interactions with the actin-based cytoskeleton.

### Eps8 is Necessary for Efficient E-Cadherin-Dependent Cell-Cell Adhesion in Human Epithelial Cells

C. Ballara,[1] G. Scita,[2] A. Disanza,[2] S. Alema[1]; [1]Istituto di Biologia Cellulare, Consiglio Nazionale delle Ricerche, Monterotondo, Italy, [2]IFOM-IEO, Milan, Italy

Epithelial cells adhere to their neighbours through specialized structures such as adherens junctions (AJ), whose core is composed of cadherins. Intercellular adhesion is a dynamic process that involves the protrusion of filopodia that orchestrate clustering of AJ proteins. Eps8, a substrate of receptor tyrosine kinases, in a complex with Abi1 and Sos-1 induces Rac activation leading to actin cytoskeleton remodelling. Recent studies have shown that Eps8 regulates the growth of actin filaments by capping their barbed ends, an activity essential for cell motility. Here, we report that Eps8 localizes at cell-cell junctions in both fibroblasts and epithelial cells. Eps8 is recruited to intercellular contacts once epithelial cell-cell adhesion is initiated and interacts with complexes containing E-cadherin and p120 catenin. We show using RNAi that reduction in Eps8 expression leads to delayed AJ formation as well as defects in cortical actin organization. Furthermore, ablation of Eps8 inhibits HGF-dependent cell scatter. These effects are reversed by reintroduction of Eps8 into RNAi cells. This study provides novel functional information on Eps8 as a cell-cell adhesion protein and increases our understanding of the roles of actin capping proteins in epithelial adhesion.

345

### Glis2: a Novel p120 Catenin-Binding Protein

C. R. Hosking, Y. Fujita; MRC Laboratory for Molecular Cell Biology, University College London, London, United Kingdom

p120 catenin (p120ctn) is an Armadillo family member, which binds to the cytoplasmic tail of cadherins at sites of cell-cell contact. It has been implicated in regulation of cell-cell adhesion and actin dynamics through its association with members of the Rho-GTPase family. However, the presence of p120ctn in the nucleus observed for a number of cell lines indicates an additional nuclear function for this protein. Using the yeast two-hybrid method, our lab has shown that p120ctn can bind to the transcription factor Glis2, a protein homologous to the Gli family that are transducers of Sonic Hedgehog signaling. We also show that p120ctn expression can induce C-terminal cleavage of the Glis2 protein. This cleavage is increased by the overexpression of Src, suggesting a role for Src-mediated tyrosine phosphorylation of p120ctn. The cleaved form of Glis2 retains its ability to bind p120ctn and DNA. Since Glis2 has been shown to have a role in neuronal differentiation, we investigated the effect

of overexpressing Glis2 in the neural tube of developing chick embryos. Interestingly, overexpressing Glis2 inhibited neuronal differentiation. This was also observed when the cleaved form of Glis2 was coexpressed with p120ctn. These results suggest a nuclear role for p120ctn by modulating the cleavage of the transcription factor Glis2, and potentially altering the transcription of genes in the neuronal differentiation pathway.

**Role of Rap1 in Regulating Epithelial Cell Junction**

S. Asuri,[1,2] N. C. Paranavitana,[1,2] L. A. Quilliam[1,2]; [1]Biochemistry and Molecular Biology, Indiana University, Indianapolis, IN, [2]Walther Cancer Institute, Indianapolis, IN

The defined architecture and function of epithelial tissues depend on cell-cell adhesion. E-cadherin mediates the primary epithelial cell junctions; adherens junctions (AJ). The goal of our study was to understand the role of the Ras-related GTPase, Rap1, in the dynamics of these E-cadherin based junctions. Individual MDCK epithelial cells showed Rap1 distributed both around the cell membrane and in the cell interior. When cells begin to establish contacts, Rap1 became enriched in this region and localized to cell junctions in established monolayers. Rap1 cycles between active GTP and inactive GDP bound states. We measured Rap1 activity in MDCK epithelial cells during formation and disruption of AJs following "calcium switching". Rap1 was activated within 2 min of calcium-chelation/cell junction disruption and this activity was sustained for at least 30 min. Rap-GTP levels were subsequently reduced upon $Ca^{2+}$ re-addition to the growth medium. Stable expression of a constitutively active Rap1A (Rap63E) mutant promoted dramatic “compaction” of MDCK cells, implying increased cell-cell contact. Whereas, dominant negative (Rap17N) mutant imparted a more “flattened” phenotype. Cells expressing Rap63E resisted hepatocyte growth factor-induced disruption of adherens junctions and cell scattering, while Rap17N cells showed accelerated cell scattering. We next explored the possibility that Rap1 influences AJ by regulating the activity of Rho proteins. Rap63E activated Cdc42 in HEK-293T cells whereas Rap17N expression reduced Cdc42 activation during $Ca^{2+}$-switching in MDCK cells. We also found that Rap1 bound FRG1, a Cdc42 GEF that has been implicated in adherens junction formation (Fukuhara et al JCB 166, 393, 2004). In summary, Rap1 is activated during disruption of junctions, yet is essential for the formation and maintenance of junctions. We therefore hypothesize that Rap1 is activated when cell junctions are disrupted and is thus “charged” to perform its functions during their reformation.

**Establishing Epithelial Cell Surface Polarity of AQP3 Upon Cell-cell Adhesion**

L. N. Nejsum, S. Yamada, W. Nelson; Molecular and Cellular Physiology, Stanford University Medical School, Stanford, CA

Aquaporins have distinct polarized localizations within the same cell: for example in collecting duct principal cells, AQP2 is apical and sub-apical, AQP3 is basal-lateral, and AQP4 is mainly basal, but little is known regarding the mechanisms involved in polarized sorting and organization of aquaporins. We sought to define the distribution of AQP3 during the early stages of development of cell polarity and formation of the basal-lateral membrane domain following cadherin mediated cell-cell adhesion. A Madin-Darby Canine Kidney (MDCK) cell line stably expressing AQP3 tagged with pEGFP was generated to follow AQP3 distribution using live cell imaging. In a single non-polarized cell, AQP3 was evenly distributed throughout the plasma membrane both on the open surface and the surface bound to the coverslip. Live cell imaging revealed that during initial cell-cell adhesion AQP3 accumulates precisely within the boundaries of the cell-cell contact and overlaps the distribution of E-cadherin-dsRed. To follow the delivery of AQ3 to the membrane, a synchronized pool of AQP3 tagged with photoactivatible (PA) GFP was photoactivated in the TGN; PAGFP-AQP3 appeared and accumulated at the site of initial cell-cell adhesion. This is the first time a non-adhesion protein has been shown to be targeted to the site of initial cell-cell adhesion following exit from the TGN. These results suggest that mechanisms involved in post-Golgi vesicle trafficking to the developing basal-lateral plasma membrane are spatially established rapidly following initiation of cadherin-mediated cell-cell adhesion.

348

**Role of Formin-1 in Endothelial Cell Adherens Junction Formation**

B. M. Gaudet,[1] S. D. Burchat,[2] J. W. R. Copeland[1]; [1]Cellular and Molecular Medicine, University of Ottawa, Ottawa, ON, Canada, [2]Biochemistry, Microbiology and Immunology, University of Ottawa, Ottawa, ON, Canada

Adherens junctions (AJs) form between adjacent cells through the homophilic interaction of transmembrane cadherins. In epithelial cells, following cadherin engagement, the intracellular domain of E-cadherin recruits β-catenin which, in turn, recruits α-catenin. α-catenin indirectly links the AJ to the actin cytoskeleton through its interaction with actin-binding proteins such as vinculin, α-actinin or formin-1. Formin-1, like other formins, contains two formin homology domains, FH1 and FH2. The FH1 domain recruits profilin-bound G-actin to the growing barbed end of an actin filament, while the FH2 domain directly nucleates actin polymerization. Recruitment of formin-1 to the AJ by α-catenin is mediated by a coiled-coil motif located N-terminal to the Formin-1 FH1. Like epithelial cells, endothelial cells also form AJs, but the role of formin-1 in AJ formation in these cells has not been investigated. We have demonstrated by RT-PCR analysis that mRNA transcripts of Formin-1 isoforms I, IV and V are expressed in human dermal microvascular endothelial cells. An antibody to the FH2 domain of murine Formin-1 has been produced and should recognize all Formin-1 isoforms. This antibody also recognizes the Formin-1 homologues from chick and humans. We are investigating the role of Formin-1 at the endothelial cell adherens junction by examining the ability of activating and interfering derivatives of Formin-1 to affect AJ formation induced by the serum mitogen sphingosine-1-phosphate. The results will be assessed by immunofluorescence using our Formin-1 antibody as well as by vascular permeability assays. Furthering our understanding of AJ formation and remodeling in endothelial cells is of great interest given the essential role these structures play in the normal functioning of the endothelium as well as in clinically relevant processes such as tumour-induced angiogenesis.

349

**Co-regulation of Cadherin and Receptor Tyrosine Kinases by Intracellular Trafficking**

S. R. Joseph, D. M. Bryant, J. L. Stow; Institute for Molecular Bioscience, University of Queensland, St Lucia, Queensland, Australia

E-cadherin is a classical adhesion protein important for such processes as establishment of polarity, maintenance of epithelial barrier function, and suppression of metastases in epithelial cells. We have previously shown that at steady state E-cadherin undergoes a dynamic trafficking through

endosomes, both during exocytosis and for recycling. Furthermore we have shown that this process can be regulated by receptor tyrosine kinases. Here we examine the intracellular trafficking of E-cadherin with EGF and FGF receptors. EGF and FGF are both able to induce internalisation of E-cadherin, with different fates for internalised protein. Similarly, localization of cognate EGF and FGF receptors is dependent on epithelial polarization or E-cadherin function in epithelial cells, suggestive of conjoint RTK/E-cadherin relationship. Long-term exposure of epithelial cells to growth factors revealed differential induction of morphological changes. Surprisingly, examination of endocytic sorting machinery revealed that growth factors also differ in their routes of E-cadherin and receptor trafficking at early timepoints after stimulation. Accordingly, distribution of E-cadherin and receptors to different endosomal compartments resulted after EGF or FGF stimulation. These findings are important in understanding differences in signalling and for transient versus permanent downregulation of cadherin-mediated adhesion.

350

**Polycystins and Adherens Junction Proteins are Integrated in a Signaling Membrane Domain**

T. Roitbak,[1] Z. Surviladze,[1] R. Tikkanen,[2] R. Sandford,[3] A. Wandinger-Ness[1]; [1]Pathology, University of New Mexico, Albuquerque, NM, [2]Biochemistry II, University of Frankfurt, Frankfurt am Main, Germany, [3]Medical Genetics, University of Cambridge, Cambridge, United Kingdom

Polycystins are plasma membrane proteins that serve to regulate epithelial cell polarity and differentiation through their function as part of several multiprotein complex with epithelial adhesive junction proteins. Defects in polycystin protein function are causal in autosomal dominant polycystic kidney disease (ADPKD) and thought to precipitate changes in cell polarity and differentiation. Biochemical and morphological studies have been used to show that the polycystins and the associated proteins E-cadherin and β-catenin distribute in a complex with the raft marker flotillin-2, but not caveolin-1. The integrity of the polycystin multiprotein complex was sensitive to cholesterol depletion as shown by cyclodextrin treatment of immunoprecipitated complexes. The C-terminus of polycystin-1 is sufficient for flotillin-2 association. Flotillin-2 was found to contain CRAC cholesterol binding domains and to promote plasma membrane cholesterol recruitment. Based on coassociation of signaling molecules, such as Src kinases and LAR protein tyrosine phosphatases, we propose that the polycystin/adherens junction multiprotein complex is embedded in a cholesterol-containing signaling microdomain specified by flotillin-2. The domain is thought to be important in the regulation of stable cell-cell adhesion. Work supported by NIDDK 50141, PKDF 12(A-C)2R, NKF F758 and DFG SFB628.

**Loss of *Smad5* in the Gut Epithelium Causes E-Cadherin Mislocalization to the Basal Membrane and Disregulation of Migration**

J. F. Schmouth,[1] B. A. Auclair,[1] A. Zwijsen,[2] D. L. Gumucio,[3] N. Perreault[1]; [1]Anatomy and Cell Biology, University of Sherbrooke, Fleurimont, PQ, Canada, [2]Developmental Biology, Catholic University of Leuven, Leuven, Belgium, [3]Cell and Developmental Biology, University of Michigan, Ann Arbor, MI

**BACKGROUND**: Bone morphogenic proteins (BMPs) are multipurpose proteins associated with the TGF-beta superfamily. The BMP proteins interacting with their receptor will trigger a signalisation cascade that is driven by the SMADs transcription factors (Smad 1, 5 and 8). Interestingly, *Smad5* null mice die at mid-gestation due to multiple embryonic defects including a vestigial gut. This suggests that *Smad5* may play an essential role in the intestine morphogenesis and cellular function. **AIM:** To investigate the in vivo function of *Smad5* in intestinal organogenesis and in intestinal epithelial cellular process such as proliferation, differentiation and migration. **METHODS AND RESULTS:** With the use of the Cre/loxP system, we generated a mice with *Smad5* exclusively deleted in the gut epithelium by crossing floxed *Smad5* mice with the Villin-Cre line. Histological analysis revealed an elongation of the cryptal compartment and an important lengthening of the villi in the *Villin-Cre/Smad5*$^{loxP/loxP}$ mice. Incorporation of BrdU during 90 minutes revealed no modifications in the number or localization of the proliferating cells in mutant mice. However, incorporation of BrdU during 48 hour made it possible to highlight an increased speed in the migration of the epithelial cells along crypt/villus axis in the mutant animals. Immunostaining with an E-cadherin specific antibody showed a change of localization in the mutant mice. E-cadherin is normally found at *Zonula Adherens* establish in the lateral membrane of intestinal epithelial cells. In the floxed *Smad5* animals, we observed a relocalization of E-cadherin mainly to the basal membrane. Western blot analysis showed an increase in protein expression of E-cadherin in the mutant mice. **CONCLUSION:** These results suggest that *Smad5* may play an important role in intestinal epithelial migration by affecting E-cadherin localization.

352

**The Wilm's Tumor-1(WT1) Interacting Protein is Expressed in the Glomerular Podocyte and Regulates Assembly of the Cell-Cell Contacts**

A. Mukherjee,[1] J. Kim,[2] A. Padiyar,[1] J. Romanello,[1] S. Schechtman,[1] M. Koniezkowski,[1] J. R. Schelling,[1] J. R. Sedor[1]; [1]Medicine/Nephrology, Case Western Reserve University, Cleveland, OH, [2]Physiology, Case Western Reserve University, Cleveland, OH

Podocyte differentiation is critical for glomerular filtration barrier function and regulated by WT1, a zinc finger transcription factor. We identified a novel, WT1 interacting protein (WTIP) that maps to human chromosome 19q13.1, a region with familial focal segmental glomerulosclerosis genes. Our hypothesis proposes WTIP normally monitors slit diaphragm and glomerular basement membrane assembly and shuttles into the nucleus after podocyte injury, providing a link between altered slit diaphragm structure and gene expression.To define WTIP function, we generated recombinant adenovirus which ectopically expressed GFP-WTIP fusion protein and found to target to cell-cell contacts. GFP-WTIP colocalized with ZO-1, beta-catenin and pan-cadherin in podocyte cell junctions. WTIP was also found to be present at ends of F-actin filaments in cultured podocytes. Similar to ZO-1 and beta-catenin, WTIP targeting to cell-cell junctions was calcium-dependent suggesting its association with adherens junctions. In subcellular fractionation experiments with rat glomeruli, WTIP is found to be co-fractionated with nephrin and caveolin. This suggests its association with nephrin in podocyte lipid rafts which comprise the slit-diaphragm in vivo. Our data indicate that WTIP is important for assembly and maintenance of adherens type cell junctions in podocytes and that of slit-diaphragm in vivo.

**Neuronal Cell Adhesion Molecule L1 Regulates Motility and Adherens Junction Formation in Breast Cancer Cells**

M. Shtutman, E. Levina, M. Baig, P. Ohouo, I. Roninson; Cancer Center, Ordway Research Institute, Albany, NY

Regulation of adherens junction formation and cell motility is important for tissue remodeling and tumor metastasis. Neuronal cell adhesion molecule L1 (L1-CAM) was recently found to play a role in growth regulation of breast cancer cells (1). To understand the function of L1-CAM in tumor cells, we studied the effects of L1-CAM knockdown and overexpression in MCF-7 breast carcinoma cell line. We find that L1-CAM knockdown enhances adherens junction formation and decreases cell motility, while elevation of L1-CAM leads to disruption of E-cadherin based cell-cell adhesion and enhancement of cell motility. In dense cultures with strengthened adherens junctions, expression of L1CAM is down-regulated; there is evidence that this down-regulation may occur through inhibition of β-catenin signaling (2). Overexpression of a truncated L1-CAM lacking the cytoplasmic domain has no effect on cell motility, indicating that intact cytoplasmic domain is required for proper functioning of L1-CAM. Our results suggest a new mechanism for tumor invasion through elevation of L1-CAM expression in tumor cells, leading to local disruption of adherens junctions and cell migration toward the tumor edge, where further elevation of L1 expression is followed by acceleration of tumor invasion and dissemination. 1.Primiano et al, Cancer Cell 2003 2.Gavert et al, J. Cell Biol, 2005

**Analysis of δ-Catenin Mutations and Modifications in Cancer**

Y. Chen, B. Jeansonne, S. K. Bareiss, Q. Lu; Department of Anatomy and Cell Biology, The Brody School of Medicine at East Carolina University, Greenville, NC

δ-Catenin, or NPRAP/neurojungin, is a unique armadillo domain-containing protein in that it is primarily expressed in the central nervous system. However, recent analysis of the human genome revealed consistently an association of *δ-catenin* mRNA sequences with cells of cancerous origin. In our most recent studies, Western blot and Tissue Micro-Array immunohistochemistry revealed a close association of increased δ-catenin expression with human primary prostatic adenocarcinomas (Lu et al., Human Pathology, 2005). δ-Catenin expression increased with prognostically significant increased Gleason scores, which was accompanied by the down regulation and redistribution of E-cadherin and $p120^{ctn}$, major cell-cell junction proteins whose inactivation is often linked to the aggressive phenotype of prostate cancer. These studies indicate that δ-catenin may be directly involved in prostate cancer progression. Presumably, the δ-catenin dependent activities increased in cancer either by the presence of dominant mutations or by an accumulation of δ-catenin protein available for pathological interactions. We therefore first compared *δ-catenin* cDNA sequences obtained from prostate cancer and benign tissue samples by RT-PCR method. No mutations were identified in the entire coding region of *δ-catenin*. This was also true for *δ-catenin* cDNA isolated from the esophageal cancer tissue samples, indicating that δ-catenin mutations in primary sequences were less likely the prominent feature in cancer. Interestingly, biochemical analyses showed that overexpressed δ-catenin underwent significant posttranslational modifications that included its phosphorylation, proteolytic processing, and redistribution in response to growth factor stimulation. In addition, overexpressed δ-catenin interacts with actin cytoskeleton and alters the cellular morphology. These data favor a model in which overexpressed δ-catenin accumulates and redistributes abnormally in cancer cells, leading to an increased interaction with cancer specific signaling pathways. This study was supported by American Cancer Society and the Department of Defense.

**Different Functions for Different Coxsackievirus and Adenovirus Receptor Isoforms**

K. J. Excoffon,[1] M. R. Avenarius,[2] N. D. Gansemer,[1] G. L. Traver,[1] R. J. Smith,[2] J. Zabner[1]; [1]Internal Medicine, University of Iowa, Iowa City, IA, [2]Otolaryngology, University of Iowa Hospitals and Clinics, Iowa City, IA

The Coxsackievirus and Adenovirus Receptor (CAR) has several significant biological functions including mediating viral infection and cell:cell adhesion. The gene encoding human CAR, *Cxadr*, is thought to consist of 7 alternatively spliced exons. Mouse *Cxadr* consists of 8 alternatively spliced exons with 2 possible c-termini: one that is similar to human *Cxadr* terminating in exon 7, the other terminates in exon 8. The last four amino acids of both isoforms encode a similar PDZ binding domain. We hypothesized that a human exon 8 form of CAR also exists. A genomic screen for human exon 8 revealed the mouse exon 8 ortholog. RT-PCR on human cell lines and tissues demonstrate expression of either $hCAR^{exon7}$ alone or both $hCAR^{exon7}$ and $hCAR^{exon8}$ combined. Notably, lung and primary cultures of polarized human airway epithelia (HAE) predominantly express $hCAR^{exon7}$. After subcloning the cDNA for $hCAR^{exon8}$, we expressed it in heterologous cell lines and compared it to $hCAR^{exon7}$. Both isoforms demonstrate similar expression levels as determined by Western blot, localization at cell:cell junctions, and adenovirus binding and infection. Interestingly, whereas $hCAR^{exon7}$ co-expression with the PDZ domain interacting protein MAGI-1b alters the localization of MAGI-1b to cell junctions, $hCAR^{exon8}$ does not. We further hypothesized that expression of $hCAR^{exon8}$ would confer HAE with a distinct phenotype. $HCAR^{exon7}$ localizes to the basolateral side of HAE providing an inherent protection from apical viral infection. In contrast, $hCAR^{exon8}$ is apical making HAE permissive for apical viral infection. These results show a differential regulation and localization of these CAR isoforms that may explain the observed differences in viral infection in distinct tissue compartments.

**Cyclic Nucleotides in Junction Restructuring During Spermatogenesis: An *In Vivo* Study**

O. Sarkar; Center for Biomedical Reasearch, Population Council, New York, NY

A plethora of evidence is presently available which demonstrates the role of cyclic nucleotides in junction restructuring. For example, numerous studies have shown cAMP and cGMP to be key regulators of junction assembly and disassembly in different *in vitro* and *in vivo* systems. In this study, we examine the role of guanylate cyclase in junction restructuring in the seminiferous epithelium of the rat testis. We demonstrate for the first time the structural interaction of soluble guanylate cyclase (sGC) with tight and adherens junction proteins in the testis. By immunoprecipitation, sGC was found to interact with occludin, JAM-A and ZO-1, as well as with cadherin, catenin, nectin, afadin, ponsin and espin, illustrating its role in cell junction dynamics. These results were corroborated by immunohistochemistry experiments which showed sGC to localize at the site of the ectoplasmic specialization. Furthermore, administration of Adjudin (formerly known as 1-(2,4-dichlorobenzyl)-1H-indazole-3-carbohydrazide), a chemical entity known to specifically perturb adhesion between Sertoli cells and germ cells (primarily round and elongate spermatids with some spermatocytes) resulted in a ~2-fold increase in sGC, coinciding with the loss of germ cells from the seminiferous epithelium. More importantly, the ability of sGC to associate with occludin during Adjudin-mediated junction restructuring in the testis was completely lost (note: the integrity of the tight junction, which constitutes the blood-testis barrier, was not affected by Adjudin treatment), whereas its association with cadherin was elevated. Taken collectively, these results clearly demonstrate that sGC function is restricted to the cadherin-

catenin complex to mediate the loss of Sertoli-germ cell contact.

**Laminin-333/α6β1 Integrin is a Non-basement Membrane Cell Adhesion Protein Complex at the Ectoplasmic Specialization of the Rat Testis**

H. Yan, C. Cheng; Population Council, New York, NY

Apical ectoplasmic specialization (ES) is a testis-specific Sertoli-germ cell actin-based adherens junction (AJ) type restricted to the interface between Sertoli cells and spermatids. Laminin γ3 was shown to be a putative binding partner of α6β1 integrin at the apical ES. However, the α and β chains that can constitute a functional laminin receptor for α6β1 integrin at the apical ES are unknown. Using RT-PCR and immunoblottings to survey all laminin α, β and γ chains in cells of the seminiferous epithelium, it was noted that α2, α3, β1, β2, β3 and γ3 chains were found in germ cells, whereas α1, α2, β1, β2, γ1 and γ3 were in Sertoli cells, implicating α3 and β3 are the plausible laminin chains restricted to germ cells that can be the bona fide partners of γ3. To verify this postulate, different cDNA constructs based on the Domain I of α3, β3 and γ3 were subcloned into pET101/D-TOPO® vector. Recombinant proteins were expressed in *E. coli* and purified using Ni-columns. Monospecific polyclonal antibodies against the α3, β3 and γ3 chains were raised in rabbits. Studies by immunoblottings, immunohistochemistry and immunofluorescence microscopy using testes and Sertoli/germ cell cocultures demonstrated that laminin α3, β3 and γ3 chains of 165, 140, 146 kDa, respectively, were indeed restricted to germ cells at the apical ES and co-localized with each other and β1 integrin. The protein levels of these three laminin chains and β1 integrin were also induced when functional apical ES was established in Sertoli-germ cell cocultures. More important, using co-immunoprecipitation technique, an anti-laminin γ3 antibody also pulled out α3 and β3 and vice versa. In summary, laminin-333 is the functional non-basement membrane receptor of α6β1 integrin at the apical ES.

## Extracellular Matrix & Cell Signaling I (358-378)

**Effect of EGF on Redistribution of P65 Nf-*KB*/rela in A431 Cells Spread on Immobilized Ligands**

O. Petukhova,[1] A. Emelyanov,[1] A. Bolshakova,[1] L. Turoverova,[1] V. Babakov,[1] I. Kropacheva,[1] K. I. Magnusson,[2] G. Pinaev[1]; [1]Cell Cultures, Institute of Cytology, St. Petersburg, Russian Federation, [2]Medical Microbiology, Linkoping University, Linkoping, Sweden

The interaction of a cell with its extracellular matrix defines a number of cellular functions, and influences gene expression. The actin cytoskeleton, by engaging membrane receptors, takes part in cell signaling stimulated by adhesive substrates. To study the influence of specific adhesion on transcription factor NF-kB activity, we have analyzed the redistribution of p65 subunits of NF-kB in A431 cells spread on immobilized ligands (fibronectin, laminin 2/4 or antibodies to EGF receptor) under the EGF action. By using double immunofluorescent staining and confocal microscopy, we compared the localization of p65 and actin cytoskeleton organization in the presence and absence of cytochalasin D, known to prevent actin polymerization. We demonstrate that spreading of A431 cells on immobilized ligands was by itself enough to induce partial p65 transport to the nucleus. The redistribution of p65 under the EGF action depended on the particular immobilized ligand, and part of the p65 population colocalized with actin structures. Cytochalasin D treatment of spread cells induced actin cytoskeleton disorganization, and both common and specific features of actin aggregate patterns were found for each immobilized ligand. P65 subunits were observed in the nucleus and cytoplasm. In the latter case, p65 was seen as large and small cytoplasmic aggregates, partly colocalizing with actin aggregates. EGF treatment resulted in reorganization and enlargement of small actin aggregates and accumulation p65 in these regions. We suggest that activated p65 uses the actin cytoskeleton as a matrix for its translocation between the cytoplasm and nucleus, and that binding of p65 to the cytoskeleton occurs in the actin polymerization points. **PDGFRβ-Mediated Phosphorylation of MUC1 Cytoplasmic Tail Promotes Its Nuclear Localization and Enhances Invasiveness in Pancreatic Ductal Adenocarcinoma Cells**

P. K. Singh,[1] R. L. Cerny,[2] M. A. Hollingsworth[1]; [1]Eppley Institute for Research in Cancer and Allied Diseases, UNMC, Omaha, NE, [2]UNL, Lincoln, NE

MUC1 is a heterodimeric transmembrane glycoprotein that is overexpressed and aberrantly glycosylated in ductal adenocarinomas. Differential phosphorylation of the MUC1 cytoplasmic tail (MUC1CT) has been associated with signaling events that contribute to proliferation and metastasis of cancer cells. We directly evaluated the *in vivo* phosphorylation status of MUC1 in pancreatic cancer cell lines by mass spectrometry-based sequence analysis of the MUC1CT. Nanospray LC-MS/MS analysis revealed a novel tyrosine phosphorylation site at the HGRYVPP sequence in MUC1CT, the first report of phosphorylation of tyrosine at this motif. Platelet-derived growth factor receptor β (PDGFRβ) was identified as a potential kinase for tyrosine at the HGRYVPP motif in the MUC1CT by analysis with the Scansite algorithm. It was confirmed by sequence analysis of the products of *in vitro* kinase assays on a synthetic 66-residue MUC1CT peptide with human recombinant PDGFRβ. Stimulation of the pancreatic cancer cell line S2-013.MUC1F with platelet-derived growth factor-BB (PDGF-BB), a potent stimulator of PDGFRβ, enhanced phosphorylation of MUC1CT. Stimulation of S2-013.MUC1F cells with PDGF-BB also increased nuclear localization of MUC1CT and its association partner, β-catenin. Although PDGF-BB stimulation had no significant effect on cell proliferation rate, it enhanced invasion *in vitro* through matrigel. Microarray analysis of PDGF-stimulated cells revealed upregulation of several metastasis related genes as compared to unstimulated or mock transfected, PDGF-stimulated cells. These results provide compelling evidence for the regulation of invasiveness of pancreatic adenocarcinoma cells by PDGFRβ-mediated phosphorylation of the MUC1CT.

**Syndecan-1 Expression in Epithelial Cells is Induced by TGFb through a PKA-dependent Pathway**

K. Hayashida, P. Park; Medicine, Baylor College of Medicine, Houston, TX

Syndecans are a major family of cell surface heparan sulfate proteoglycans (HSPGs) and they modulate a wide variety of biological molecules through their heparan sulfate (HS) moiety. Although all syndecans contain the ligand-binding HS chains, they likely perform specific functions *in*

*vivo* because their temporal and spatial expression patterns are different. However, how syndecan expression is regulated has yet to be clearly defined. In this study, we examined how induced expression of syndecan-1 is regulated in epithelial cells. Our results showed that among several bioactive agents tested, only TGFβ2 and forskolin induced syndecan-1 expression on normal murine mammary gland (NMuMG) epithelial cells. TGFβ1 and TGFβ3 also induced syndecan-1 expression on NMuMG cells and other epithelial cells, such as A549 human lung carcinoma and C127 transformed murine mammary gland cells. Interestingly, TGFβ treatment inhibited proliferation of epithelial cells in response to FGF-2 in an HS-dependent manner, suggesting that the inhibitory effects of TGFβ on epithelial cell proliferation are partly mediated by HS chains of syndecan-1. Epithelial syndecan-1 induction by TGFβ was significantly inhibited by transient expression of a dominant-negative PKA cDNA construct and also by specific inhibitors of PKA, such as KT5720 and myristoylated peptide inhibitor, but not by inhibitors of PKC. Steady-state syndecan-1 mRNA was not increased by TGFβ treatment, indicating that TGFβ induces syndecan-1 expression through PKA in a post-transcriptional manner. TGFβ treatment induced phosphorylation of an invariant serine residue in the cytoplasmic domain of syndecan-1. Further, PKA was co-immunoprecipitated from epithelial cell lysates by an anti-syndecan-1 antibody and PKA phosphorylated the syndecan-1 cytoplasmic domain *in vitro*. These findings uncover a novel regulatory mechanism where TGFβ, PKA, and the cytoplasmic domain of syndecan-1 coordinate to regulate expression of syndecan-1 at the cell surface.

**Rapidly Dephosphorylated- and Perinuclear Golgi-Translocated-PKCalpha is Upstream of Calcium and PLD in Lacritin Mitogenic Signaling, Respectively Through NFATC1 and mTOR**

N. Wang,[1] J. Wang,[1] R. Raab,[2] R. McKown,[2] G. W. Laurie[1]; [1]Department of Cell Biology, University of Virginia, Charlottesville, VA, [2]Department of Integrated Science and Technology, James Madison University, Harrisonburg, VA

Lacritin is an apically released mitogen of some exocrine glands with suggested roles in targeted epithelial renewal and secretion as it flows downstream. Lacritin binding of syndecan-1 core protein is a key step in lacritin-dependent mitogenesis, but little is known of its mitogenic signaling pathway. Previous signaling studies revealed that lacritin-dependent calcium mobilization was pertussis toxin- ($G\alpha_i/G\alpha_o$), U73122- (phospholipase C) and Go 6976- (protein kinase C) sensitive. Neither p42 nor p44 are activated indicating that lacritin signaling is distinct from the Ras-GTP-dependent pathway utilized by many growth factors. Here we focused on the putative role of PKC in lacritin-responsive HSG cells, and identified downstream effectors. Depletion of PKCα by siRNAs D7 and D10 abrogated lacritin-stimulated (10 nM) mitogenesis without affecting proliferation by FBS. Lacritin and N-24 deletion mutant, but not C-25 deletion mutant, promoted PKCα translocation to the perinuclear Gogli region coincident with PKCα dephosphorylation. Dephosphorylation was detectable by 1 min, returning to baseline by 30 min. PLD1 is also located in the perinuclear Golgi region and is activated by PKCα in response to lacritin. A mitogenic pathway from PLD through mTOR is indicated by the capacity of rapamycin to completely inhibit lacritin-dependent proliferation. Depletion of PKCα inhibited calcium mobilization and NFATC1 nuclear translocation. Inhibition of NFATC1 translocation by cyclosporin also completely inhibited lacritin-dependent mitogenesis. Lacritin's C-terminal binding of syndecan-1 thus leads to targeting of downstream mTOR and NFATC1 via $G\alpha_i$ or $G\alpha_o$/PKCα-PLC/PLD/mTOR and $G\alpha_i$ or $G\alpha_o$/PKCα-Ca/calcineurin/NFATC1 for mitogenesis.

**Syndecan-1 as a Coreceptor For Prosecretory Mitogen 'Lacritin' in a Core Protein-Specific and GAG-Free Selective Manner**

P. Ma,[1] S. Beck,[1] R. Raab,[2] R. McKown,[2] G. Coffman,[2] A. Rapraeger,[3] G. W. Laurie[1]; [1]Department of Cell Biology, University of Virginia, Charlottesville, VA, [2]James Madison University, Harrisonburg, VA, [3]University of Wisconsin-Madison, Madison, WI

Lacritin is a small glycoprotein secreted by human lacrimal acinar cells. Lacritin acts in an autocrine or paracrine manner at low nanomolar levels to respectively promote further lacrimal secretion and ductal proliferation. How lacritin targets cells is unknown. Here we report on lacritin affinity purification of several cell surface proteins and identification of syndecan-1 as a putative lacritin co-receptor. The first of approximately four bands repeatedly eluted from lacritin affinity column was determined by sequencing to be syndecan-1. In pull-down assays, lacritin bound mammalian syndecan-1, but not syndecan-2 or 4. Binding is to the core protein, preferentially to a form lacking heparan sulfate glycosaminoglycan. The suggestion that local heparanase activity might regulate lacritin binding to the ubiquitously expressed syndecan-1 was confirmed by RNA interference and mitogenesis. Deletion of lacritin's C-terminal 25 but not N-terminal 5,10, or 24 amino acids eliminated binding. Soluble lacritin and N-terminal 24 deletion mutant but not heparin and C-terminal deletion mutants inhibited binding in competitive binding assays. Syndecan-1 was detected in 'near apical' and basolateral plasma membranes in human lacrimal gland. Syndecan-1, a coreceptor for FGF's, Wnt's and other growth factors appears to serve in the same capacity for lacritin, but in a unique manner apparently independent of heparan sulfate side chains. Such selectivity, apparently heparanase-dependent suggests a dynamic new mechanism by which epithelial renewal can be regulated. Dependence on lacritin's C-terminal 25 amino acids for binding, as well as mitogenesis and calcium signaling, suggests involvement of lacritin's C-terminal amphipathic α-helix in lacritin-receptor interactions. **Analysis of the Mammary Epithelial Cell Secretome: Regulation Through Epidermal Growth Factor Receptor Transactivation**

J. M. Jacobs, R. D. Quesenbery, L. E. Kathmann, D. G. Camp, R. D. Smith, B. D. Thrall; Biological Sciences Division, Pacific Northwest National Lab, Richland, WA

The survival, proliferation, and motility of human mammary epithelial cells (HMECs) are thought to depend on proteins secreted or shed into the extracellular space, yet the diversity of proteins released by these cells and the mechanisms underlying their regulation are poorly understood. Here, we report a comprehensive analysis of the "secretome" from an HMEC line. We applied the accurate mass and time tag approach to selectively identify and quantitate via comparative mass spectrometry (MS) proteins released from HMECs both constitutively and in response to the protein kinase C agonist, PMA. In addition to stimulating PKC, PMA causes transactivation of the epidermal growth factor receptor (EGFR), an autocrine pathway required for HMEC growth and motility. Thus, we also investigated the role of EGFR transactivation in regulating protein release from HMECs. We used capillary liquid chromatography (LC) combined with tandem MS to identify peptides and create a mass and time tag database for application in high-throughput LC-Fourier transform-ion cyclotron resonance MS analyses. Nearly 900 proteins were identified confidently from HMEC-conditioned medium, which was consistent with previous predictions of the large diversity of the mammalian secretome. Proteins

whose release was stimulated by PMA treatment included ligands for receptor signaling pathways as well as a variety of proteins with proteolytic function. Selective blockage of EGFR signaling using either an EGFR kinase inhibitor or neutralizing receptor antibody inhibits secretion of a subset of PMA-stimulated extracellular proteins, including several matrix metalloproteinases (MMPs). Regulation of MMP secretion through EGFR transactivation is mediated through transcriptional induction and involves EGFR-dependent activation of the extracellular signal-regulated kinases. Furthermore, cytokine-induced secretion of MMP was also EGFR-dependent, suggesting that EGFR transactivation is a general regulatory mechanism cells use to selectively modify their extracellular environment in a context-dependent manner.

**Participation of CTGF in Skeletal Muscle Fibrosis**

C. Vial, P. Cañón, E. Brandan; Cell & Mol. Biol., Catholic University of Chile, Santiago, Chile

Duchenne muscular dystrophy (DMD) is characterized by degeneration of muscle fibres, which leads to progressive muscular atrophy. Regeneration of these is dependent on the activation and proliferation of progenitor myoblasts, process that in DMD is insufficient to compensate for the continuous loss of myofibers and fibrotic scarring ensues. Connective tissue growth factor (CTGF) has been related to fibrotic processes for his ability of inducing connective tissue synthesis. CTGF is augmented in fibrotic disorders, but there is little information regarding its role in skeletal muscle disease, as well as its biological receptor. It has been reported that CTGF binds to the low-density lipoprotein receptor-related protein (LRP), and that it binds directly to integrins. The aim of our study is to elucidate CTGF's role in skeletal muscle biology with relation to pathological fibrosis, and to study its receptor in myoblasts. Here we report that TGF-β and lysophosphatidic acid (LPA), two molecules involved in tissue scaring, induce CTGF expression in C2C12 mouse myoblast cell line in a dose dependent manner. In order to study the effect of CTGF in myoblasts we have generated a recombinant active CTGF (rCTGF). Here we report that incubation of myoblasts with rCTGF stimulates the production of fibronectin, collagen Iα2, and proteoglycans. In order to study CTGF´s receptor we have also use a siRNA to inhibit LRP and RGDS to inhibit integrins, resulting in an altered response to the cytokine. These results suggest that LRP might be an internalization receptor for CTGF and that in DMD not only are fibroblasts involved in the increase of connective tissue, but myoblasts can contribute to muscle fibrosis. (Supported by MDA3790, FONDAP, MIFAB)

**A Novel Regulatory Mechanism of TGFβ Signalling by Decorin and LDL Receptor-Related Protein (LRP)**

C. Cabello-Verrugio, M. Paz Marzolo, E. Brandan; Cell & Mol. Biol., Catholic University of Chile, Santiago, Chile

Skeletal muscle differentiation is a process strongly inhibited by TGFβ *in vitro*. Three proteoglycans, whose expression is regulated during myogenesis, are able to bind TGFβ and regulate its biological effects: decorin, biglycan and betaglycan. Decorin, a soluble proteoglycan, can interact with diverse proteins, among them growth factors, extracellular matrix proteins, and cell surface receptors. We have previously demonstrated that myoblast decorin null clone (Dcn null) shows an accelerated differentiation due to decreased sensitivity to TGFβ. Moreover, we have recently demonstrated that LDL receptor-related protein (LRP) is an endocytic receptor for decorin in myoblasts. The aim of this work is to understand the mechanism responsible for the decreased sensitivity to TGFβ in Dcn null myoblasts. We show that Dcn null myoblasts are less responsive to TGFβ than wild type myoblasts, evaluated by TGFβ-dependent p3TPlux reporter activity. This effect is specific for decorin since decorin re-expression in Dcn null myoblasts restores TGFβ's response to wild type levels. This difference in TGFβ's response is not produced by changes in levels of TGFβ receptors, Smad proteins or in TGFβ-dependent Smad-2 phosphorylation. Moreover, we show that in wild type myoblasts RAP (an inhibitor of LRP-ligand endocytosis) or a specific siRNA to LRP both inhibit p3TPlux activity to the level found in the Dcn null myoblasts. The specificity of this effect is demonstrated by re-expressing decorin in Dcn null myoblasts treated with RAP or siRNA to LRP both decrease p3TP-lux activity. Therefore, we demonstrate that decorin regulates TGFβ signalling in myoblasts through a novel mechanism involving LRP but not Smad-2 phosphorylation. (Supported by FONDAP, MIFAB, HHMI, CONICYT AT-24050108)

**Cystatin Inhibits TGF-β Mediated Signaling in B16F10 Melanoma**

V. N. Onkoba; Biochemistry, Kirksville College of Osteopathic Medicine, Kirksville, MO

Cysteine proteases are extracellular matrix-degrading enzymes that have been shown to play a critical role in tumor invasion and metastasis of several human cancers. Urokinase plasminogen activator (uPA) and its inhibitor PAI (plasminogen activator inhibitor)-1, both members of the plasminogen activating system, are increased in tumors. Studies have shown that overexpression of PAI-1, as noted in several cancers, increases the invasive capacity of tumor cells thus establishing a pro-metastatic role for PAI-1. Our lab previously showed that cystatin C, a natural cysteine protease inhibitor, plays a role in decreasing invasion in B16F10 melanoma metastasis. Although a previous study by Sokol and Schiemann (2004) showed that cystatin C binds to the transforming growth factor-β1 (TGFβ) type-I receptor, the mechanism by which cystatin C inhibits metastasis still remains unclear. In this study, we focused on downstream effects of the Smad pathway, which is activated following TGF-β1 phosphorylation. We compared uPA, PAI-1, Smad 2/3 and p-Smad 2/3 levels in TGF-β1-treated cells incubated with or without cystatin S. Our methods included: RT-PCR, Western blot and immunofluorescence. Immunofluorescence studies showed that TGF-β1 induced perinuclear and nuclear translocation of p-Smad 2/3. TGF-β1 caused a decrease in uPA message levels whereas p-Smad 2/3 levels increased and Smad 2/3 levels remained unchanged. Western blot analyses showed cystatin S inhibits increased p-Smad 2/3 levels. PAI-1 message levels were also inhibited by cystatin S treatment. Taken together, our findings suggest that cystatins decrease the invasive potential of melanoma via the TGF-β1 signaling pathway and could offer promise as anti-metastatic agents.

**Ionizing Radiation Predisposes Human Mammary Epithelial Cells to TGFß induced Epithelial to Mesenchymal Transition**

K. L. Andarawewa, A. C. Erickson, W. S. Chou, M. Barcellos-Hoff; Cancer Biology, Lawrence Berkeley National Laboratory, Berkeley, CA

Ionizing radiation (IR) is a known human breast carcinogen. Many aspects of the association between radiation and breast cancer have been elucidated in the past decades. Previous studies have demonstrated that radiation elicits a rapid and dynamic program of extracellular matrix remodeling that is in part mediated by the activation of TGFß. Although the mutagenic capacity of IR is widely acknowledged as the basis for its

action as a carcinogen, we and others have shown that IR can also induce growth factors and extracellular matrix remodeling. In recent studies we have shown that IR, compromises human mammary epithelial cell (HMEC) polarity and multicellular organization in a manner characteristic of neoplastic progression through a heritable, non-mutational mechanism. Since colonies arising from irradiated HMECs exhibited traits of cancer progression we postulated that IR predisposes HMECs to undergo persistent phenotypic changes and this phenotype is augmented by TGFß. To test this hypothesis we characterized the irradiated phenotype in nonmalignant HMEC in presence or absence TGFß. We have demonstrated that irradiated single HMEC in presence of TGFß can generate a persistent phenotype in daughter cells characterized by change in cell morphology, increased expression of mesenchymal markers, such as N-cadherin, fibronectin and vimentin, decreased expression of epithelial markers, E-cadherin and ZO-1, and increased cellular motility when compared to sham controls or following single treatments. These phenotypic changes are hallmarks of an epithelial to mesenchymal transition (EMT) event which is a signature of an aggressive type of tumor in vivo. Thus, we show IR predisposes HMECs to TGFß induced EMT and promote neoplastic progression.

**Adhesion to the G3 Domain of Laminin-5 Promotes the Osteogenic Differentiation of Human Mesenchymal Stem Cells through an ERK Dependent Pathway**

R. F. Klees,[1] R. M. Salasznyk,[1] T. R. Scott,[2] A. Boskey,[3] G. E. Plopper[1]; [1]Biology, Rensselaer Polytechnic Polytechnic, Troy, NY, [2]Department of Animal and Veterinary Sciences, Clemson University, Clemson, SC, [3]Biology, Hospital for Special Surgery, New York City, NY

The overall mechanisms governing the osteogenic differentiation of human mesenchymal stem cells (hMSC) are poorly understood, as well as the role of laminins in bone development. We previously reported that laminin-5 induces an osteogenic phenotype in hMSC and does so through an extracellular signal-related kinase (ERK) dependent pathway. We hypothesized that this is a result of integrin-ECM binding, and that it occurs via the known alpha3 G3 integrin binding domain of laminin-5. To test this hypothesis we cultured hMSC on several different globular domains of laminin-5 in the presence and absence of a specific ERK inhibitor, PD98059. hMSC adhered best to G3, and this adhesion maximally activated ERK within 120 minutes. Prolonged culturing (16 days) of hMSC on G3 led to activation and expression of key osteogenic markers (bone sialoprotein 2, osteocalcin, alkaline phosphatase) in hMSC, and induced a significant increase in the phosphorylation of the master bone gene Runx2. These effects were reduced when cells were cultured in the presence of PD98059. G3 binding did not increase matrix mineralization, demonstrating that G3 alone is not sufficient to induce complete osteogenic differentiation in vitro. We conclude that G3 mediates attachment of hMSC to laminin-5 and that this adhesion stimulates most, but not all, of the osteogenic differentiation associated with laminin-5 binding to hMSC.

**Mechanical Crosstalk and Feedback Between Integrins and ERK**

M. J. Paszek,[1] N. Zahir,[1] K. R. Johnson,[1] M. Dembo,[2] D. A. Hammer,[1] V. M. Weaver[3]; [1]Bioengineering and Institute for Medicine and Engineering, University of Pennsylvania, Philadelphia, PA, [2]Biomedical Engineering, Boston University, Boston, MA, [3]Pathology and Institute for Medicine and Engineering, University of Pennsylvania, Philadelphia, PA

Integrin and growth factor signaling cooperatively activate MAP kinase to regulate gene expression and cell behavior. Although mechanical cues such as cell adhesion are known to regulate integrin and growth factor signaling, how mechanical force could elicit effects on cell signaling has yet to be defined. We used a combination of pharmacological and genetic approaches together with a force-measurement technique called traction force microscopy to delineate the molecular mechanisms whereby mechanical force could influence ERK signaling. We showed that application of an exogenous force facilitates focal adhesion maturation and cell spreading through enhancement of β1 integrin clustering. Ectopic clustering of β1 integrin through expression of a β1 integrin self-clutering mutant also drove focal adhesion maturation and cell spreading in association with increased ERK activation and cell force generation, suggesting that a functional link between focal adhesions, ERK activity and force may exist. Consistently, we documented a correlation between Rho and ROCK activity, focal adhesion and cell force generation and implicated ERK as a key feedback regulator in this signaling circuit. Indeed, we could show that ERK activity correlates with cell force generation and that inhibiting ERK represses cellular forces in part by decreasing ROCK expression. Additional studies using synthetic flexible polyacrylamide substrata suggest that normal cells employ an ERK-integrin-Rho signaling-force circuit and tune their tensional homeostasis to the mechanical properties of the matrix microenvironment to regulate their growth and behavior. We also found that aberrant stiffening of the tissue microenvironment or uncoupling of the cellular tensional homeostasis signaling circuitry contributes to malignant behavior of an epithelium. **Caveolin-1 Regulates Collagen Expression and Myofibroblast Differentiation in Normal Lung Fibroblasts Through MEK/ERK Signaling**

E. V. Tourkina,[1] M. Richard,[1] K. Charles,[2] R. M. Silver,[1] S. Hoffman[1]; [1]Rheumatology, Medical University of SC, Charleston, SC, [2]South Carolina State University, Orangburg, SC

Scleroderma (systemic sclerosis) is an autoimmune connective tissue disease that is frequently complicated by pulmonary fibrosis. Scleroderma lung fibroblasts, or myofibroblasts (SLF) overexpress collagen and contain high levels of activated MEK/ERK under baseline conditions. Our previous results demonstrate that caveolin-1 depletion activates MEK/ERK and increases collagen expression in normal lung fibroblasts (NLF). To determine whether increasing caveolin-1 activity will have the opposite effect, NLF and SLF received the caveolin-1 scaffolding peptide, a treatment known to mimic caveolin-1 overexpression. Similar striking effects were observed in both cell types. The treatment completely blocked collagen accumulation while decreasing MEK/ERK phosphorylation about 50%. Similar results were obtained when adenovirus was used to overexpress caveolin-1 in each cell type. To determine whether caveolin-1 also regulates myofibroblast differentiation, we evaluated whether perturbation of caveolin-1 would affect expression of the myofibroblast marker alpha-smooth muscle actin (ASMA). Depleting caveolin-1 increased ASMA expression in NLF, but had no effect on the already high level of ASMA in SLF. Conversely, overexpressing caveolin-1 decreased ASMA levels in SLF, and had little effect on the low levels of ASMA in NLF. Our observations that low caveolin-1 levels are correlated with high collagen levels and MEK/ERK activation in vitro were confirmed in vivo in mice with bleomycin-induced lung fibrosis and in vitro in lung tissue samples collected from human patients with scleroderma lung disease and from normal individuals. Therefore, these observations suggest that in lung fibroblasts caveolin-1 regulates both collagen expression and myofibroblast differentiation.

**Growth Factor Receptor or Erk MAP Kinase Inhibition Rescues Dysfunctional 3D-Mammary Epithelial Acinus Assembly**

E. McArdle, E. Gilligan, L. Thornton, J. Murtagh, F. Martin; Conway Institute, University College Dublin, Dublin, Ireland

Primary mouse mammary epithelial cells supported on a laminin-rich ECM, form 3D-acinar assemblies consisting of single layers of polarised, quiescent cells surrounding a cleared lumen. Inhibition of JNK results in failure of cell polarisation, lumen clearance and formation of dysfunctional spheres filled with surviving cells. Our objective was to characterise the component cells of these dysfunctional spheres and understand the regulatory mechanisms determining their behaviour. We show that these cells exhibit low expression of and non-polarised distribution of tight junction proteins, low relative expression of E-cadherin but high N-cadherin expression, coupled with expressing smooth muscle actin and vimentin. These are characteristics of epithelial cells initiated on transition to a mesenchymal phenotype. These cells also showed high levels of EGF-receptor autophosphorylation and ERK and Bim phosphorylation. We show that the 3D-assemblies forming in the presence of the JNK inhibitor, SP600125, properly polarise and undergo lumen clearance if they are cultured without growth factor (EGF) or in the presence of an EGF receptor autophosphorylation inhibitor. However, these spheres are significantly smaller than normal. ERK phosphorylation and Bim phosphorylation levels are reduced under these conditions. In fact the presence of the ERK signalling pathway inhibitor, PD98059, also protects against the dysfunctionalising effects of the JNK inhibitor. Indeed, after exposure to JNK inhibiton and the formation of dysfunctional spheres, addition of PD98059 is sufficient to 'rescue' and trigger cell polarisation, lumen clearance and generation of a normal acinar structure. But again these spheres are significantly smaller than normal. Thus integrin activation by the ECM and JNK act to support anti-proliferative and pro-apoptotic influences that include suppressing ERK activation and supporting cell-cell contacts. Inhibition of JNK is sufficient to promote cell proliferation, cell survival and the expression of EMT-like characteristics.

**Tumor Necrosis Factor-α Induces VCAM-1 Expression via Activation of MAPKs and NF-κB in Human Tracheal Smooth Muscle Cells**

C. Yang, C. Lee; Pharmacology, Chang Gung University, Tao-Yuan, Taiwan Republic of China

TNF-α has been shown to induce the expression of adhesion molecules in airway resident cells and contribute to inflammatory responses. Here, the roles of mitogen-activated protein kinases (MAPKs) and NF-κB in TNF-α-induced expression of vascular cell adhesion molecule (VCAM)-1 were investigated in human tracheal smooth muscle cells (HTSMCs). TNF-α-enhanced expression of VCAM-1 protein and mRNA as well as phosphorylation of p42/p44 MAPK, p38, and JNK were significantly attenuated by inhibitors of MEK1/2 (U0126), p38 (SB202190), and JNK (SP600125). Transfection with dominant negative mutants of MEK1/2, ERK1, ERK2, p38, and JNK attenuated TNF-α-induced VCAM-1 expression. Furthermore, TNF-α-induced VCAM-1 expression was significantly blocked by a selective NF-κB inhibitor helenalin. TNF-α-stimulated translocation of NF-κB into the nucleus and degradation of IκB-α was blocked by helenalin, but not by U0126, SB202190, or SP600125. VCAM-1 promoter activity was enhanced by TNF-α in HTSMCs transfected with VCAM-1-Luc, which was inhibited by helenalin, U0126, SB202190, and SP600125. Moreover, the resultant enhancement of VCAM-1 expression increased the adhesion of polymorphonuclear cells to monolayer of HTSMCs which was blocked by helenalin, U0126, SB202190, or SP600125. These results suggest that in HTSMCs, activation of p42/p44 MAPK, p38, JNK and NF-κB is essential for TNF-α-induced VCAM-1 expression.

373

**The p38 MAPK Pathway is Essential for Mallory Body Formation in vitro**

L. Nan, F. Bardag-Gorce, J. Li, B. A. French, S. W. French; Pathology, LA Biomedical Research Institute, Torrance, CA

To determine if the p38 MAPK pathway plays a role in Mallory body (MB) formation, primary cultures of hepatocytes from DDC-primed mice were studied. The DDC-primed hepatocytes were MB free when isolated and began to enlarge and elongate after a few hours of culture. MBs began to form spontaneously after 2-3 days of culture and numerous MBs were formed after 6 days of culture. The p38 MAPK inhibitor (p38i) was added to the medium 3 hours after planting the cultures. No MBs formed in the cells treated with 100μM p38i for 6 days and the cells stayed polyhedral in shape just as they appeared prior to culturing and in the 3h culture. Western blot showed that the formation of phosphorylated p38 MAPK was completely blocked in DDC-primed hepatocytes by p38i treatment. Immunostaining of 6 day DDC-primed hepatocyte cultures with antibodies to p62 and phospho-p38 MAPK showed that phosphorylated p38 MAPK was concentrated within MBs. The immunostaining was also used to determine phosphorylated p38 MAPK expression in the livers of 4 different groups of mice: control mice; mice fed DDC for 10 weeks; mice fed DDC 10 weeks, then withdrawn 5 weeks; mice fed DDC 10 weeks, withdrawn 4 weeks, then fed DDC + chlormethiazole (CMZ) for 1 week. P38 was located in the cytoplasm of the hepatocytes and at the fringe of the MBs. These data indicate that activated p38 MAPK may be involved in the mechanism of MB formation by phosphorylating cytokeratins, which overload the ubiquitin-proteasome pathway leading to keratin aggresome formation. The p38 MAPK pathway may also be involved in MB formation by activating the transcription factors such as ATF-2. ATF-2 regulates the critical proteins involved in MB formation such as Ubiquitin B and p62.

374

**Directed Cell Fate by Engineered Spatial Patterns of BMP-2**

J. A. Jadlowiec,[1] E. D. Miller,[2] G. Fisher,[1] L. Weiss,[3] A. Waggoner,[1] P. G. Campbell[4]; [1]Molecular Biosensor and Imaging Center, Carnegie Mellon University, Pittsburgh, PA, [2]Biomedical Engineering, Carnegie Mellon University, Pittsburgh, PA, [3]Robotics Institute, Carnegie Mellon University, Pittsburgh, PA, [4]Institute for Complex Engineered Systems, Carnegie Mellon University, Pittsburgh, PA

During development, morphogens (hormones) and their inhibitors form discrete temporal and spatial patterns within the extracellular environment, including the incorporation within discrete extracellular matrices (ECMs). Such hormone patterns, both concentration gradients and discrete periodic shapes, are proposed to direct cell fate determination and lineage progression. Experimental approaches to establish defined persistent spatial hormone patterns, required for systematic study of cell differentiation, have remained a significant challenge. We have developed an ink jet-based bioprinting technology to engineer persistent and defined spatial patterns of hormones biologically immobilized (solid-phase) on biomimetic substrates. Our objective was to demonstrate the ability to direct differentiation of primary human adult mesenchymal stem cells (hMSC) towards an osteoblastic lineage using 2-dimensional spatial patterns of solid-phase bone morphogenetic protein-2 (BMP-2). Our strategy utilized our ink-jet printing technology to create biologically-inspired solid-phase patterns of BMP-2, an important hormone during tissue development including

bone. We assessed cell response by detection of Smad signal transduction pathway activation based on the rationale that Smads are the "first responders" to receptor activation by BMP-2. We demonstrated that solid-phase BMP-2 is biologically active: Smad signaling was activated and downstream target genes were induced. We quantified Smad1 sub-cellular localization and determined that Smad1 was predominantly nuclear for cells on pattern, in register with printed BMP-2. Whereas, control cells (cells off BMP-2 pattern), exhibited mainly cytoplasmic Smad1. We conclude that Smads can be used to identify a patterned cell response to solid-phase patterns of BMP-2, and may be useful to predict changes in cell fate and response to spatial patterns of morphogens. Our long term goal is to engineer cell differentiation in register to a hormone stimulus in a temporally and spatially-defined manner.

**Bone Morphogenetic Protein 4 Alters Epithelial Ovarian Cancer Cell Morphology, Motility and Adhesion**

B. L. Theriault, M. W. Nachtigal; Pharmacology, Dalhousie University, Halifax, NS, Canada

**Introduction:** We identified a functional bone morphogenetic protein (BMP) signaling pathway in human epithelial ovarian cancer (EOC) cells. EOC cells can adhere to extracellular matrix (ECM) proteins through integrin receptors and focal adhesion proteins (FAPs). These proteins likely contribute to EOC progression by facilitating cell adherence to peritoneal surfaces. BMP4 treatment results in altered cell morphology characterized by increased cell spreading. *We hypothesize that BMP signaling plays a role in EOC morphology, adhesion and motility by remodeling cell-ECM interactions.* **Methods**: EOC cells were treated with BMP4 for up to 7 days. F-actin staining and vinculin co-localization was used to view cytoskeletal changes. Quantitative PCR (QPCR) assessed mRNA levels of integrin receptors, FAPs and ECM proteins. An *in vitro* wounding assay evaluated EOC motility in response to BMP4 or BMP4 plus Noggin (BMP inhibitor), while cell adhesion to various ECM proteins was observed using a tritium incorporation assay. An adenovirus expressing the constitutively active Type I BMP receptor (Ad-Alk3QD) was also used to transduce EOC cells. **Results**: BMP4-induced cell spreading correlated with increased stress fiber formation and colocalization of vinculin to actin stress fibers; this morphological change was irreversible. QPCR showed increased integrin, FAP and ECM mRNA as early as 24hrs following BMP4 treatment. EOC cells demonstrated increased cell motility and adhesion in the presence of BMP4, while co-treatment of BMP4 and Noggin reduced motility to control levels. Ad-Alk3QD produced similar morphological changes as with exogenous administration of BMP4. **Conclusions**: BMP4 signaling induces changes in the molecules involved in cell morphology, adhesion and motility, translating into changes in cellular behavior. Future work will examine the intracellular signaling mediators responsible for producing this committed morphological change, enhancing our understanding of how BMP4 signaling may contribute to EOC biology.

**Dual Regulation of Type IV Collagen by Smad1 in Diabetic Nephropathy:TGF-b and BMP4**

H. Abe,[1] T. Tominaga,[1] T. Matsubara,[2] K. Nagai,[2] T. Takahashi,[1] H. Arai,[2] T. Kita,[2] T. Doi[1]; [1]University of Tokushima, Tokushima, Japan, [2]Kyoto University, Kyoto, Japan

We previously reported that advanced glycation end-products (AGEs) transcriptionally upregulate the type IV collagen (Col4), a key molecule for diabetic nephropathy. To identify a specific transcriptional factor, we used a yeast one-hybrid system to isolate a clone that encodes a specific binding protein from a mouse mesangial cell cDNA library. We identified this clone as the cDNA that encodes Smad1. We confirmed the binding of Smad1 to the Col4 promoter in vivo using chromatin immunoprecipitation (ChIP) assay. Transfection of Smad1 induced 23-fold increase of transcriptional activity of Col4 in COS7 cells. Smad1 is transcriptionally upregulated by AGEs in a time-dependent manner in mouse mesangial cells. Similarly, the levels of Col4 mRNA increased in parallel with the upregulation of Smad1 transcripts. Although Smad1 is an essential gene for renal development and is little expressed in normal adult glomeruli, Smad1 is significantly induced by AGEs stimulation. Moreover, knock-down of the Smad1 by antisense morpholino blocked the excessive collagen production. As Smad1 is generally known to transduce BMP4 signaling, we also demonstrated that AGEs induced BMP4, Smad1, and Col4 mRNA and protein expressions in mesangial cells. TGF-b neutralizing antibody or Noggin (a BMP antagonist) inhibited these inductions. Furthermore, Smad1 and BMP4 were highly expressed in mouse diabetic nephropathy. These results suggest that the modulation of both TGF-b/Smad1 and BMP4/Smad1 signaling is deeply responsible for initiation and progression of diabetic nephropathy and that blocking of Smad1 signaling pathway may be beneficial for diabetic complications.

**Tenascin-C EGF-Like Repeats - Novel Matrikine Ligands for EGFR**

A. V. Iyer,[1] K. T. Tran,[1] L. Richardson,[2] C. W. Borysenko,[1] H. C. Blair,[1] I. Bahar,[3] L. Griffith,[2] A. Wells[1]; [1]Department of Pathology, University of Pittsburgh, Pittsburgh, PA, [2]2School of Engineering Biological Engineering Division and Department of Chemical Engineering, Massachusetts Institute of Technology, Cambridge, MA, [3]Department of Computational Biology, University of Pittsburgh, Pittsburgh, PA

Select epidermal growth factor (EGF)-like repeats (EGFL) of human tenascin cytotactin can stimulate EGF receptor (EGFR) signaling. However, this activation requires micromolar concentrations of soluble EGFL in contrast to subnanomolar concentrations of classical growth factors such as EGF. To elucidate the underlying mechanism of this altered EGFL binding phenomenon, and assess if such binding resulted in distinct biochemical/biophysical responses as compared to prototypical growth factors, we recombinantly expressed 14$^{th}$ EGFL (Ten14) in monomeric form and tested them on murine fibroblasts over-expressing EGFR. Radio-ligand binding assays showed that Ten14 did not bind stably to EGFR, and there was no significant internalization of Ten14 over either the short or long term, both in contrast to EGF, suggesting altered binding dynamics for Ten14. Surface plasmon resonance analysis yielded a $K_D$ of 97μM for Ten14, approximately three logs higher than for EGF. We modeled Ten14 using structure prediction servers to produce a tight EGF-like molecule with truncated loops. Analysis of the generated bound structure suggested both Ten14 and EGFR have much more mobility in the binding pocket compared to EGF/TGFα, due to the absence of key high-affinity interactions which likely account for the low affinity binding of Ten14, and implies a flexibility enabling ligandation of receptor even when EGFL are embedded within the extracellular matrix. Such matrix-constrained presentation of EGFL would likely result in compartmentalization of EGFR on the cell surface, where PLCγ1 is predominantly activated, resulting in enhanced cell migration. Indeed, we observed sustained migration over 2D surfaces at levels of Ten14 that failed to stimulate proliferation, concomitant with potent PLCγ1 and M-calpain signaling, and weak activation of ERK/MAPK, p90Rsk and Elk1. Thus, this comprehensive study puts forth a novel mode of action for EGFL signaling through EGFR, and how this impacts cellular behavior.

378

**Endotoxin-Induced IL-6 and iNOS/NO Expression in Non-Immune Mouse Mammary Epithelial Cell Lines**

S. W. Maalouf,[1] R. S. Talhouk,[2] F. L. Schanbacher[1]; [1]Animal Sciences, Ohio State University, Wooster, OH, [2]Biology, American University of Beirut, Beirut, Lebanon

Recent findings link sustained inflammation to chronic disease or cancer in epithelia. Although inflammation in immune cells shows coordinate regulation of inflammatory respondents interleukin-6 (IL-6) and nitric oxide (NO) by nuclear factor kappa B (NFkB), little is known about such inflammatory responses in non-immune cells of epithelia. This study investigated IL-6 secretion, NO production, and induction of nitric oxide synthase (iNOS) relative to cell types and substratum during induced inflammation in mammary epithelia. Two mammary cell lines (CID-9 =heterogeneous (secretory epithelial, myoepithelial and fibroblast) cells; and SCp2 =subculture of CID-9 predominantly secretory epithelial and lacking myoepithelial cells) were grown with differentiating hormones on plastic +/-EHS extracellular matrix (ECM) before inducing inflammation with bacterial endotoxin (ET; 0-100ug/ml). ET-induced inflammatory responses were monitored by IL-6 secretion (ELISA immunoassay), NO production (Griess reaction assay), and IL-6 and iNOS mRNA expression (real-time PCR). Both cell types showed early ET dose-dependent induction of IL-6 secretion that plateaued by 6h with maximal IL-6 secretion 2-3-fold higher in CID-9 (ca 600 pg/ml) than in SCp2, especially on ECM. IL-6 mRNA peaked by 3h in CID-9 regardless of substratum. NO did not increase until 12h after ET treatment and continued throughout the 48h culture, with little or no difference between substratum or ET dose for either cell line. iNOS mRNA peaked at 3-6h and declined sharply thereafter in SCp2 but was sustained over 3-12h in CID-9 cells, with higher iNOS mRNA for SCP2 on ECM. The mutual upregulation with differences by cell type for IL-6 and iNOS in ET-treated mammary cells suggest coordinate but poorly understood differential regulation of inflammatory responses (and role for NFkB therein) by respondent and epithelial cell types or differentiation state, for which mammary epithelial cells are a good model.

## Cell-Cell Interactions I (379-393)

379

**Regulation of Connexin43 Expression and Function by Calreticulin**

M. Aghasi,[1] E. Kardami,[2] N. Mesaeli[1]; [1]Division of Stroke and Vascular Disease, Winnipeg, MB, Canada, [2]Institute of Cardiovascular Sciences, Winnipeg, MB, Canada

Gap junction channels between neighboring cells facilitate cell-cell communication and influence different processes in the cells, including proliferation and differentiation. Connexins are the building blocks of gap junctions. They are synthesized and folded in the endoplasmic reticulum and oligomerized in their way to the cell membrane. They have short half life and after internalization undergo degradation via both proteasome and lysosome. To date, no chaperons have been identified involving in the folding of connexin43. Calreticulin (CRT) as an endoplasmic reticulum resident chaperon indirectly regulates expression and function of a variety of proteins in cell. To elucidate the role of CRT in the regulation of connexin43 expression and function we utilized wild type and CRT knockout mouse embryonic fibroblast cells. Our data showed significantly higher connexin 43 protein in the CRT knockout cells. We also showed that this increase in the protein level was due to activation (2 fold) of connexin43 promoter. Interestingly, there was lower gap junction density at the cell-cell junction and a significant decrease in the gap junction function (dye transfer) in the absence of CRT. Inhibition of proteasome activity resulted in increased connexin43 localization to the plasma membrane and vesicular structures in the CRT knockout cells. Furthermore, inhibiting protein degradation via proteasome resulted in a significant decrease in connexin43 promoter activity while blocking lysosome activity had no effect. We conclude that in the absence of CRT Connexin43 is more sensitive to proteasome degradation and it would be internalized faster resulting in decreased gap junctional communication. Moreover, enhanced proteasome activity in CRT knockout cells stimulates connexin43 promoter activity.

**CLIC4 Plays Key Role in the Interaction Between Neural Photoreceptors and Retinal Pigment Epithelial Cells**

J. Chuang, C. Sung; Ophthalmogy, Dyson Vision Research Institute, Weill Med College of Cornell University, New York, NY

Retinal pigment epithelium (RPE) is part of the outermost layer of retina, sandwiched between the photoreceptor and choriocapillaries. Tight junctions formed between RPE cells prevent passive diffusion of molecules and allow the RPE to serve as the blood-retina barrier. The apical surfaces of RPE cells contact the subretinal space, which contains interphotoreceptor matrix and the distal tips of photoreceptor outer segments (OS). The basolateral surfaces interact with Bruch's membrane and choriocapillaries. In addition, RPE cells are professional phagocytic cells, participating in the diurnal phagocytic removal of spent photoreceptor OS tips. The development of RPE and photoreceptor is orchestrated by a two-way communication between the RPE and the neural retina; they mature around the same time postnatally. Unfortunately, the intimate relationship between RPE and photoreceptor interface is hard to model in vitro. By immunohistochemistry, we found that CLIC4, a member of the family of intracellular chloride channels (CLICs), was highly abundant in the apical microvillar processes of RPE. CLICs are a family of closely-related proteins sharing high homology across approximately 220 amino acids. Previous studies showed that CLIC4 generated an outwardly rectifying Cl- conductance upon reconstitution in a planar lipid bilayer, however, conductance was very low. We sought to study CLIC4's role in RPE in vivo by loss-of-function approach using an in vivo transfection method that delivers plasmids into the RPE layer of animals. RPE cells with CLIC4 suppressed by CLIC4-siRNA but not control-siRNA exhibited profound changes in cytoskeleton arrangement and protein expression pattern. More interestingly, the structural remodeling of RPE was associated with the retinal detachment and photoreceptor atrophy. We propose that CLIC4 is a key molecule involved in cytoskeletal organization of RPE, and critical for the interface between RPE-neural retinas.

381

**Cellular Regulation of the Hematopoietic Stem Cell Niche**

J. M. Gillette, J. Lippincott-Schwartz; Nichd, cbmb, National Institutes of Health, Bethesda, MD

The defining characteristics of stem cells make them remarkable. Not only do they have extensive proliferative potential, but they also have an ability to differentiate into multiple cell types. It is becoming increasingly clear that stem cell functions are regulated by both intrinsic stem cell factors and neighboring differentiated cells. This unique microenvironment is referred to as the stem cell niche. Hematopoietic stem cells (HSC),

which give rise to the blood and immune cell lineages, reside in the bone marrow. Recent studies have demonstrated osteoblasts, the bone forming cells, as critical components of the HSC niche. However, the cellular interactions between HSC and osteoblasts are not well defined. We utilized live cell imaging techniques to observe the physical relationship between HSC and osteoblastic cells cultured together. Studies carried out with human $cd34^+$ cells labeled with FM dyes in the presence of osteoblastic stromal cells expressing fluorescent proteins show a number of interesting interactions between the cells. Imaging began within 10 minutes of co-culture and a series of Z stack images were taken every 10 minutes for a 16 hour period. Time lapse monitoring displayed HSC attach to the osteoblastic monolayer within 20 minutes. Although attachment is maintained to one osteoblast, our imaging data suggest that HSC migrate on the osteoblastic surface for distances up to 10µm. Additionally, immunofluorescence experiments using the cd34 surface molecule of HSC detected clusters of progenitor cells lodged at specific osteoblastic sites suggestive of HSC proliferation. In combination these data demonstrate that the *in vitro* model system is valuable for observing the dynamic cellular interactions that occur between HSC and the osteoblastic 'niche' microenvironment.

382

**ß-actin is Locally Translated and Accumulated at the Cell Periphery and Cell Contacts**

A. J. Rodriguez, S. M. Shenoy, R. H. Singer, J. Condeelis; Anatomy and Structural Biology, Albert Einstein College of Medicine, Bronx, NY

We developed a live cell imaging technique demonstrating that ß-actin mRNA, its sites of translation, and ß-actin protein were spatially correlated at the periphery of C2C12 mouse myoblast cells. However, in order to determine how ß-actin is locally translated and the newly synthesized protein sorted, a live cell imaging technique is required to correlate the distribution of translating ß-actin mRNA with the trafficking of newly synthesized ß-actin protein. ß-actin mRNA was actively translated in both the perinuclear cytoplasm and at the cell periphery. In contrast, ß-actin mRNA lacking the zipcode, a sequence necessary and sufficient for its localization to the cell periphery, was unable to translate there, confirming that the zipcode determines the sites of localized translation. At regions of cell-cell contact, ß-actin mRNAs were actively translating suggesting that these are microenvironments where translational repression was relieved. Pulse-chase staining showed that newly synthesized ß-actin protein accumulated at the leading edge of isolated cells or at cell-cell contacts. However, ß-actin synthesized from an mRNA lacking a zipcode sequence failed to accumulate either at the leading edge of isolated cells or at cell-cell contacts. Therefore, enrichment of newly synthesized protein at these sites was dependent on mRNA localization. These data demonstrate that the site of translation of a protein is an important component of its final disposition. This work was supported by NIH grants CA100324 to JC, AR41480 to RHS, and AR4148012S1 to AJR.

**Role of Epithelial CD44 in Regulation of PMN Transepithelial Migration**

K. Zen, C. A. Parkos; Pathology, Emory University, Atlanta, GA

Neutrophil (PMN) migration across mucosal epithelium during inflammatory episodes is a multistep process involving many cell surface molecules and signaling events. To identify epithelial ligands for migrating PMN, we screened a panel of antibodies generated against epithelial cells for inhibition of PMN transepithelial migration in the basolateral to apical direction. We identified a mAb termed gamma-35 that inhibited PMN transepithelial migration and strongly labeled the apical surface of intestinal epithelial cells. The expression of the antigen recognized by gamma-35 was significantly increased after exposure of epithelial cells to INF-γ. Microsequence analysis of the antigen purified from epithelial cells identified it as an epithelial-specific CD44 isoform. This protein is a highly glycosylated 150 kD membrane protein that, unlike other CD44 isoforms, is not expressed on PMN. MAb gamma-35 had no inhibitiory effects on PMN migration across acellular filters, suggesting the inhibition of migration is mediated by blockage of epithelial CD44. Kinetic studies of PMN transepithelial migration and immunofluorescencce localization experiments demonstrated that mAb gamma-35 blocked detachment of PMN from the apical surface of epithelial monolayers at a late stage of transmigration and suggest that epithelial CD44 is involved in regulating PMN detachment. Analyses of supernatants from transmigration assays revealed the presence of soluble epithelial CD44 following PMN transmigration, suggesting that shedding of epithelial CD44 might play a role in regulating PMN detachment from epithelia. In support of this hypothesis, both the shedding of epithelial CD44 and PMN transepithelial migration were blocked by mAb gamma-35 and MMP inhibitors. Taken together, these studies suggest that epithelial CD44 regulates PMN detachment during transepithelial migration and may be a novel target for anti-inflammatory therapies.

**Differential Association of Tyrosine 421- and 466-Phosphorylated Cortactin with Cell-Cell Contacts and Cytoskeleton in Corneal Endothelial Cells**

N. Savion, L. Kredy-Farhan; Goldschleger Eye Research Institute, Tel Aviv University, Tel Hashomer, Israel

Cortactin (p80/85), a phospho-tyrosine protein known as an actin-associated protein, was recently shown to be localized at cell-cell contacts in confluent epithelial and endothelial cells. Therefore, in the present study we explored the localization and association of the two tyrosine-phosphorylated variants of cortactin ($pY^{421}$ and $pY^{466}$) with the cytoskeleton and cell-cell contacts in cultured bovine corneal endothelial (BCE) cells. Cortactin expression and localization was determined by immunoblot and confocal microscopy, respectively, using specific antibodies against cortactin and its tyrosine-phosphorylated variants $pY^{421}$ and $pY^{466}$. Triton X-100 insoluble proteins were considered as cytoskeleton associated proteins. In confluent monolayer of BCE cells cortactin appeared as a fine continuous single line marking the cell-cell contacts close to but not in visible co-localization with the cortical actin-ring that appeared as a wide continuous ring in each cell. Only cortactin isoform p85 was observed phosphorylated on residues $Y^{466}$ or $Y^{421}$. This fine line of cortactin at cell-cell contacts was mainly phosphorylated at $Y^{466}$, while cortactin at the basal aspect of the cell, probably at focal adhesion sites, was phosphorylated at $Y^{421}$. Furthermore, upon cell-cell contacts formation, up-regulation of cortactin $pY^{466}$ was demonstrated. Cortactin was partially associated with cytoskeleton ptoteins (46±4% in the Triton X-100 insoluble fraction) and this fraction was phosphorylated on $Y^{421}$, while the soluble fraction was mainly phosphorylated on $Y^{466}$. In non-confluent cells, only cortactin $pY^{421}$ was found and localized at the leading edges of the cell, along the focal contacts (co-localized with FAK) and the actin stress-fibers. These results may suggest that in BCE cells cortactin $pY^{466}$ is involved in cell-cell contacts, while cortactin $Y^{421}$ is associated with focal adhesion sites. Furthermore, the non-tyrosine-phosphorylated cortactin molecules are preferentially associated with the cytoskeleton.

**Synchronization of the Beating of the Cardiomyocytes by the Heterologous Cells with the Agarose Microchamber System**

T. Kaneko, K. Kojima, K. Yasuda; Graduate School of Arts and Sciences, University of Tokyo, Tokyo, Japan

To understand the community effect in cardiomyocytes, the stepwise network formation of cells as the reconstructive approach using the on-chip agarose microchamber system with photo-thermal etching method was applied. In this system, the shapes of agarose microstructures were changed step by step with photo-thermal etching of agarose layer of the chip using a focused laser beam (wavelength: 1064 nm or 1480 nm) to increase the interaction of cardiomyocytes during cultivation. We tried to control the beating of two cardiomyocytes and the cardiomyocytes through the constitutive arrangement of the connection to the fibroblasts. It was observed that the beating of cardiomyocytes synchronized suddenly after dozens of minutes, after cardiomyocytes contacted physically. Furthermore, when the number of cardiomyocytes was increased step by step, the fluctuation of the beating intervals of the cardiomyocytes was stabilized. However, when the beating of cardiomyocytes was synchronized through the fibroblasts arranged between the cardiomyocytes, it was observed that the beating of cardiomyocytes synchronized after the synchronization and asynchronization of the beating repeatedly for dozens of minutes. These results indicate the importance of the community size and the heterogeneity of cells to stabilize their performance for making cell-network model for using cells for monitoring their functions like the tissue model.

386

**Ouabain Changes the State of Phosphorylation and Localization of Adhesion and Signaling Proteins**

D. Flores-Benitez, C. E. Flores-Maldonado, I. Larre, F. García-Santín, L. Shoshani, M. Cereijido, R. G. Contreras; Departamento de Fisiología, Biofísica y Neurociencias, CINVESTAV-IPN, D.F., Mexico

In a previous work we described a P→A mechanism that transduces occupancy of the $Na^+,K^+$-ATPase (P = pump) by ouabain, into changes in phosphorylation and retrieval of cell-cell and cell-substrate attaching (A) molecules, thus causing a release of the cell from the monolayer. P→A involves activation of protein tyrosine kinases (PTKs) and of Extracellularly Regulated Kinases (ERK1/2), as well as an increase in the cell content of $p190^{Rho\text{-}GAP}$, a Rho GTPase promoter. Here we observe that one of the PTKs activated by ouabain is c-Src, whose inhibition with PP2 prevents cell detachment. The activation of PTKs is necessary for the phosphorylation of ERKs, a step that can be blocked by genistein. Phosphorylated ERKs are in turn necessary for the inactivation and decrease of cell content of RhoA; this last effect can be prevented by the ERK inhibitor UO126. Pursuing the effect of ouabain on cell detachment, we observe that inhibition of c-Src (with PP2) or ERK1/2 (with PD98059) prevent retrieval of occludin, β-catenin and focal adhesion kinase (FAK), which are conspicuous members of tight, adherens and focal junctions respectively. Retrieval of β-catenin appears to be associated to an increase of tyrosine phosphorylation mediated by ERK1/2. FAK instead is dephosphorylated on tyrosine 397, a process which is also mediated by c-Src.

387

**T Cell Exosomes Enhance Lipid Accumulation in Human Macrophages**

S. Dadsetan, L. Zakharova, A. F. Fomina; Physiology and Membrane Biology, University of California, Davis, Davis, CA

Activated human T cells release vesicles, termed exosomes, originated from endocytic compartments. We reported previously (Fomina et al. 2003. *Exp. Cell Res.* 291:150-66) that exosomes substantially differ in lipid composition from the plasma membrane as they are composed of cholesterol enriched raft membranes and expose phosphatidylserine at their outer membrane leaflet. The development of macrophage-derived foam cells that contain massive amounts of cholesterol esters is a hallmark of atherosclerotic lesions and is mediated by scavenger receptors that recognize phosphatidylserine. Because activated T cells are abundant in atherosclerotic lesions we explored whether T cell exosomes would affect lipid accumulation in macrophages. Resting T lymphocytes were purified from the peripheral blood of healthy volunteers and were activated in vitro with phytohemagglutinin P to stimulate exosome release. Exosomes were isolated from T cell culture supernatants using high speed centrifugation. Pellets obtained from T cell cultures displayed positive staining with cholera toxin B and annexin V and were composed of vesicles with the size and shape typical for T cell exosomes. The preparation of T cell exosomes was added to the culture of differentiated human macrophages. After overnight incubations, macrophages were fixed and stained with Oil red O, a lipoprotein-sensitive dye. Subsequent confocal imaging study revealed that macrophages incubated with T cell exosomes were enlarged in size and accumulated a significantly larger amount of lipoproteins than control cells. These results support the hypothesis that exosomes released by activated T cells are internalized by human macrophages resulting in enhanced macrophage growth and lipid accumulation. Research described in this abstract was supported by Philip Morris USA Inc. and Philip Morris International.

**Formation of Rosettes between Autologous Cultured Monocyte-Macrophages and Lymphocytes: Analysis by a Regression Model**

I. T. C. Novak, H. R. Cabral; Institute of Cell Biology, National University of Cordoba-Argentina. Faculty of Medicine, Cordoba-Argentina, Argentina

We found a selective cell-cell interaction with formation of rosettes between human blood monocyte-derived macrophages and lymphocytes (MLRs) in samples harvested under certain conditions from total leukocyte cell cultures (Rev Fac Cienc Med Cordoba 50 (2):25-6, 1992; Mol Biol Cell 7:S, 603a, ASCB 1996; Mol Biol Cell 8:S, 414a, ASCB 1997; Am J Hematol 60: 285-8, 1999). We found that the lymphocytes that joined to monocyte-macrophages in MLRs are T CD4+, and this phenomenon is time and cell density dependent. We found that gangliosides inhibited it partially (Mol Biol Cell 12:S, 477a, ASCB 2001). We postulated that antigen presentation would be involved in MLRs and we found that CD66 monoclonal antibodies recognize neutrophil material phagocitized by macrophages that formed immunological synapses and MLRs (Mol Biol Cell 13:S, 393a, ASCB 2002). Co-cultured naive purified macrophages and lymphocytes produces few MLRs and immunologic synapses but if antigens are added both phenomena are stimulated. (Mol Biol Cell 14:S, 458a, ASCB 2003). Inhibitors of antigen processing and presentation such as Brefeldin A (BFA) and Chloroquine inhibited these phenomena (Mol Biol Cell 15:S, 94a, ASCB 2004). We postulated that the cell-cell interaction in MLRs may be culture-time dependent. Here, we study the relation of MLRs and culture-time employing a Regression Model to obtain the equation of adjusted model. Methods: autologous human total leukocyte cultures from 30 healthy donors. Samples were harvested at various times: 15, 24, 48, 72, 96 and 120 hours of culture and centrifugated and performed as previously reported. Results: (R square 0.964), ANOVA for

Regression ($p<0.0001$). The equation obtained was: RML= -0.402 + 0.109 culture hours. These results support our hypothesis that a linear relation between MLRs formation and culture-time occurs.

**A Liquid Miscibility Model of Tumor-Stromal Interaction in Prostate Cancer**

D. Jia, J. Parron, M. Nurzia, J. Rosenthal, S. Kesler, R. A. Foty; Surgery, UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ

We present a model in which prostate cancer-stromal interaction can be modeled as a liquid miscibility/immiscibility phenomenon, rooted in the same thermodynamic principles that govern the interactions between simple liquids. We apply an analogy of the high energy interaction between ethanol and water resulting in miscibility of the two phases, or the lower energy of interaction between oil and water resulting in immiscibility, to demonstrate that the model can differentiate between such interactions between mixtures of prostate cancer (CaP) and stromal cells. We show that when differentially-labeled non invasive AT-2 or invasive MLL cells are mixed with rat prostatic fibroblasts (RPF), AT-2 cells segregate from RPF cells, while MLL cells remain intermixed, suggesting that MLL-RPF interaction is of higher energy than that of AT-2 and RPF. A switch in the composition of the prostatic stroma from smooth muscle (SMCs) to fibroblastic is a hallmark of malignant transformation in CaP. We mixed MLL cells either with rat prostatic SMCs or RPF cells and showed that MLL cells segregate from SMCs but intermix with fibroblasts. This indicates that MLL cells have higher affinity for prostatic fibroblasts than for SMCs and is consistent with the observation that the stroma of more aggressive prostate cancers is predominantly fibroblastic. Further, we show that altering the adhesive relationship between tumor and stromal cells can shift a high affinity invasive interaction to one of lower affinity resulting in a shift from cell intermixing to segregation. We treated MLL cells with MEK inhibitors (MEKi) and showed that treatment restored the ability of MLL cells to assemble fibronectin into a fibrillar matrix leading to increased cell-cell cohesion and segregation from RPF cells. Our model provides a basis for exploring epithelial-stromal interaction in an easily manipulated *in vitro* system.

**A Neuronal Membrane Protein Required for Dendrite and Glial Process Extension in *C elegans***

M. G. Heiman, S. Shaham; Rockefeller University, New York, NY

Nervous system assembly and function rely on the coordinated development of complex cell shapes. The *C. elegans* amphid, the primary sensory organ of the worm, is a model for neuron and glial cell morphogenesis. It consists of 12 sensory neurons that each extend an axon and a dendrite, and two glia, one of which extends a process that is tightly bundled to the dendrites. Although axon development is well-studied, little is known about how dendrites or glial processes form. To understand dendrite and glia morphogenesis, we conducted a visual screen for mutants with defective amphid morphology. We identified mutants in two genes, *dex-1* and *dyf-7*, in which dendrites fail to grow, a novel phenotype we call Dex (*d*endrite *e*xtension defective). Notably, axons appear normal, indicating that dendrite growth requires different machinery than axon growth. In addition to shortened dendrites, Dex mutants display shortened glial processes. In some mutants, dendrites and glial processes are of variable lengths within a population, yet in a single amphid are always of equal length, revealing that dendrite and glial process extensions are coupled. We cloned *dyf-7* and found that it encodes a putative membrane protein with a conserved extracellular domain. *dyf-7* is expressed in neurons and required at the time of dendrite extension. Promoter-swap experiments show it can act in neurons or, suprisingly, in glia. A truncated DYF-7 protein, predicted to be secreted, is capable of rescuing *dyf-7* mutants. Thus, DYF-7 likely acts in the extracellular milieu. To understand how *dyf-7* promotes dendrite growth, we have established an optical cell-marking system to visualize dendrite extension in real-time. Because DYF-7 contains a conserved domain implicated in neuronal morphogenesis in other systems, amphid development may reflect a conserved means of sensory organ formation.

**TGFβ2 Inhibits Angiogenesis in a Novel *In Vitro* 3-D Model of the Respiratory Mucosa**

H. G. R. Thompson, D. T. Truong, C. K. Griffith, S. C. George; Biomedical Engineering, University of California, Irvine, Irvine, CA

Asthma is a chronic disease of the bronchial airway resulting in airway constriction. Local factors repair injured tissue, resulting in airway remodeling including vascularization. The current study developed an *in vitro* 3-D model of the human airway to analyze capillary sprout formation and network complexity in response to physiologic concentrations of TGFβ2 seen under conditions of epithelial injury. Many factors are known to influence angiogenesis and wound healing, including members of the VEGF and TGFβ families. Previous findings in our lab indicate that primary human bronchial epithelial cells (NHBE) increase soluble active TGFβ2 in response to mechanical denudation. The exact nature of TGFβ2 involvement is still under debate with conflicting results. The current model modifies a previous tissue construct in which primary human umbilical cord vein endothelial cells (HUVECs) were seeded onto cytodex microcarrier beads suspended in fibrin. Primary human lung fibroblasts (NHLF) were plated atop the fibrin gel at a distance supporting diffusion of soluble mediators. Our modification adds a differentiated primary NHBE cell layer seeded on a permeable Transwell membrane cultured at an air-liquid interface. Characterization of angiogenesis is defined by total capillary network length, number of vessel sprouts per bead, and number of vessel segments. TGFβ2 and VEGF concentrations were assessed by ELISA This *in vitro* tissue construct models many cell-cell interactions of lung tissue *in vivo*. In particular, NHLFs support capillary development, and NHBE induce further capillary network formation, supporting the role of VEGF in vascularization. Exogenous addition of VEGF further induces tube formation and network length. While TGFβ2 inhibits tubulogenesis in a dose-dependent manner, it also increases secreted VEGF suggesting that TGFβ2-inhibited angiogenesis is not regulated via the MEK/ERK pathway.

392

**Differential Adhesion Specifies Topology of Pseudoislets of pancreatic beta and alpha cells**

D. Jia, D. DaJusta, V. Peng, K. Bennett, R. A. Foty; Surgery, UMDNJ-Robert Wood Johnson Medical School, New Brunswick, NJ

Islet cell transplantation represents a promising cure for Type I diabetes. However, human islets available for transplantation are in extremely limited supply. Identifying an alternative source of cells and their constitution into functional islets is an important goal for the treatment of this disease. Cellular organization in pancreatic islets is evolutionarily conserved, non-random, and perturbed in diabetes suggesting that islet topology influences function. Understanding the mechanisms underlying the establishment of islet topology and its impact on function will facilitate the

design process. Isolated islet cells self-assemble in vitro into pseudoislets with the same cell type organization as native islets. It is widely held that differential adhesion contributes to the concentric segregation of islet cell types in vitro and in vivo. This postulate has never been directly tested since, until recently, no method existed which could rigorously quantify differences in adhesive properties of islet cells. We developed tissue surface tensiometry specifically for this purpose. We show that (1) randomly mixed immortalized beta (INS-1, MIN6) and non-beta (alpha-TC) cells sort-out in vitro in configurations resembling those of native islets with INS-1 and MIN6 cells forming the core and enveloped by alpha-TC cells; (2) aggregates of internally-segregating INS-1 and MIN6 cells are substantially more cohesive (2.52 dynes/cm, 1.35 dynes/cm, respectively) than those of the externally-segregating alpha-TC line (0.63 dynes/cm); (3) altering the cohesivity of alpha-TC cells results in phase reversal further confirming that differential adhesion specifies in vitro pseudoislet topology; (4) topology is not specified by differential expression of either cadherins or N-CAM but rather may be associated with differential capacity for fibronectin matrix assembly. Collectively the data strongly indicate that differential adhesion is the physical mechanism underlying the non-random organization of cells in pancreatic islets.

### Endothelial Cells Increase Tumor Cell Invasion into 3D Collagen Gels

C. T. Mierke, J. Pauli, P. Kollmannsberger, B. Reischl, W. H. Goldmann, B. Fabry; Center for Medical Physics and Technology, Biophysics, University of Erlangen-Nuremberg, Erlangen, Germany

Endothelial cells cultured as a monolayer on a gel or membrane are known to form a barrier against leukocyte and fibroblast cell invasion into the underlying extracellular matrix. Here we investigated whether endothelial cells can also form a barrier against tumor cells. We developed a 3D collagen gel assay to analyze invasion depth and number of invaded tumor cells in the presence or absence of a closed endothelial monolayer. We tested 13 tumor cell lines isolated from different organs (breast, skin, lung, brain, bladder and pancreas). Endothelial cells were isolated from human umbilical vein and used from 1$^{st}$ to 2$^{nd}$ passage. Tumor cells were stained with carboxyfluorescein diacetate and DNA-intercalating dye Hoechst 33342 to distinguish them from endothelial cells. Transmigration and invasion of tumor cells (seeded at 200 cells/sqmm) were analyzed after 3 days by computer-assisted optical 3D sectioning using a motorized fluorescent microscope. Images stacks were taken in 2 µm increments, and the invasion depths of each tumor cell was recorded. We quantified invasiveness for each tumor cell line in the presence and absence of an endothelial monolayer as average invasion depth (in mm) times number of invasive tumor cells per sqmm field of view. Except for T47D breast carcinoma cells, all tumor cell lines showed dramatically increased invasion in the presence of endothelial cells. Averaged over all cell lines, invasiveness was 1.88/mm ± 0.28 in the absence and 7.55/mm ± 1.25 in the presence of endothelial cells ($p < 0.001$). These results demonstrate that endothelial cells are unable to form a barrier against tumor cells and, surprisingly, even stimulate invasion of tumor cells, regardless of their tissue origin. These findings suggest a new role that endothelial cells may play in the process of tumor cell metastasis.

### Novel Functional Interaction between $Na^+/H^+$ Exchanger 1 and Tyrosine Phosphatase SHP-2

J. Xue,[1] D. Zhou,[1] H. Yao,[1] M. J. McConnell,[2] B. D. Gelb,[3] G. G. Haddad[4]; [1]Pediatrics, Albert Einstein College of Medicine, Bronx, NY, [2]Medicine, Mount Sinai School of Medicine, New York, NY, [3]Pediatrics and Human Genetics, Mount Sinai School of Medicine, New York, NY, [4]Pediatrics and Neuroscience, Albert Einstein College of Medicine, Bronx, NY

Besides being a $pH_i$ regulator, $Na^+/H^+$ exchanger 1 (NHE1) has recently been postulated as a membrane scaffold to assemble protein complexes and coordinate various signaling pathways. The aim of the current study is to uncover NHE1 interactive proteins and study their functional implications. NHE1 interactive partners were screened in the mouse brain using a signal transduction antibodyarray. Ten out of 400 tested proteins appeared to be potentially associated with NHE1. These partners have been shown to be involved in either cell proliferative or apoptotic pathways. The interactions between NHE1 and tyrosine phosphatase SHP-2, Bin 1 or heat shock protein 70 were reciprocally confirmed by co-immunoprecipitation. Furthermore, the functional significance of the association between NHE1 and SHP-2 was investigated for intracellular pH ($pH_i$) regulation and for cell proliferation using the fluorescent dye BCECF and [$^3$H]-thymidine incorporation respectively. Our data revealed that cells with SHP-2 overexpression exhibited a higher steady-state $pH_i$ and a faster, $Na^+$-dependent $pH_i$ recovery rate from acid load in the HEPES buffer. Moreover, the inhibition of cell proliferation by NHE1 blockade (HOE642) was diminished in these SHP-2 overexpressing cells. Taken together, our findings demonstrate that SHP-2 is not only associated with NHE1 but also positively modulate NHE1 functions such as $pH_i$ regulation and cell proliferation. This work was supported by National Institutes of Health grants PO1HD32573 and RO1NS037756 to Gabriel G. Haddad.

### Annexin II Light Chain p11 is an N-Terminal Auxiliary Subunit of Acid-Sensing Ion Channel ASIC1a

E. Donier,[1] F. Rugiero,[1] K. Okuse,[2] J. N. Wood[1]; [1]Molecular Nociception Group, Department of Biology, University College London, London, United Kingdom, [2]Department of Biological Sciences, Imperial College, London, United Kingdom

Acid-Sensing Ion Channels (ASICs) are voltage-independent $H^+$-gated ion channels belonging to the amiloride-sensitive DEG/ENaC superfamily of receptor channels. They have been implicated in a wide variety of physiological functions, such as nociception, mechano-transduction, learning, memory and fear behaviour, visual transduction and cochlear function. Recently homomeric ASIC1a channels were shown to be a major non-voltage-gated pathway for $Ca^{2+}$ entry in cells and $Ca^{2+}$ overload through ASIC1a channels was proven to make a major contribution to hippocampal neuronal damage in stroke. Therefore, the search for factors regulating ASIC1a function has become more pressing with respect to the development of selective pharmacological agents. We have used a rat dorsal root ganglion cDNA library in a yeast 2-hybrid assay to identify proteins that interact with ASICs. We found that the annexin II light chain p11 physically interacts with the N-terminus of ASIC1a but not other ASIC isoforms. Co-expression of p11 and ASIC1a in CHO-K1 cells, lead to a 2-fold increase in expression of the ion channel at the cell membrane, as judged by membrane-associated immunoreactivity and cell surface biotinylation. Consistent with these findings ASIC1a peak currents in transfected CHO-K1 cells were upregulated 2-fold in the presence of p11, whilst ASIC-3 mediated currents were unaffected by p11 expression. Neither the pH dependence of activation or rates of desensitisation were altered by p11, suggesting its primary role in regulating

ASIC1a activity is to enhance cell surface expression of ASIC1a. These data demonstrate that p11, already known to traffic members of the voltage-gated sodium and potassium channel families, as well as Transient Receptor Potential and chloride channels, also plays a selective role in enhancing ASIC1a expression.

396

**Transient Receptor Potential Thermo-Sensitive Channels Mediate Cytosolic Calcium Influx in Synoviocytes**

M. Y. Kochukov, T. A. McNearney, Y. Fu, Y. H. Ma, K. N. Westlund; University of Texas Medical Branch, Galveston, TX

The transient receptor potential (TRP) channels are important membrane sensors, responding to thermal, chemical, osmotic or mechanical stimuli by activation of calcium and sodium fluxes. In this study, we detected expression of three distinct TRP-channels and established their role in mediating cytosolic calcium ($[Ca^{2+}]_c$) response in tumor-derived SW982 synoviocytes and primary cultures of human synovial cells from patients with inflammatory arthropathies. Using Fura-2 ratio measurements while incubating cells in a temperature regulated chamber, we observed significant $[Ca^{2+}]_c$ elevation elicited by rapid changes in bath temperature, application of TRPV1 receptor agonists, capsaicin and resiniferatoxin, or a cold receptor stimulator, icilin. No changes in $[Ca^{2+}]_c$ were produced by menthol. Temperature thresholds for calcium response were determined to be 12 ± 1 ºC for cold and 28 ± 2 ºC for heat activation. Temperature increases or decreases beyond these thresholds resulted in a significant rise in the magnitude of $[Ca^{2+}]_c$ spikes. Observed changes in $[Ca^{2+}]_c$ were completely abolished in Ca-free media and resulted from direct Ca entry through TRP channels rather then by activation of voltage-dependent calcium channels. RT-PCR detected two heat sensitive channels, TRPV1 and TRPV4, and a cold-sensitive channel, TRPA1. No mRNA for TRPV3 or TRPM8 was amplified. The RT-PCR results support the data obtained with the $[Ca^{2+}]_c$ measurements. TRPV1 channels were also detected immunohistochemically with increases in staining after capsaicin. We propose that the TRP channels are functionally expressed in human synoviocytes and may play a critical role in adaptive or pathological changes in articular surfaces during arthritic inflammation. Supported by The Dana Foundation and NIH P01 NS011255-31.

**Protein Expression of G-Protein Inwardly Rectifying Potassium Channels (GIRKs) in Breast Cancer Cell Lines**

M. S. Dhar,[1] H. K. Plummer[2]; [1]Large Animal Clinical Sciences, University of Tennessee, Knoxville, TN, [2]Pathobiology, University of Tennessee, Knoxville, TN

Previous data from our laboratory has indicated that there is a functional link between the beta-adrenergic receptor signaling pathway and the G-protein inwardly rectifying potassium channel (GIRK1) in breast cancer cell lines and these pathways were involved in growth regulation of these cells (BMC Cancer, 2004 4:93). These previous studies indicated gene expression of GIRK channels. To continue these studies, we determined GIRK protein expression. Protein levels were determined by western blotting after isolation of membrane associated proteins. Expression of GIRK1 at the indicated molecular weight (MW) for the antibody (62 kDa) was seen in the breast cancer cell lines MDA-MB453 and ZR-75.1. In addition, GIRK1 expression was seen at a lower MW in the MDA-MB361, MDA-MB468, MCF-7, ZR-75.1 and MDA-MB453 cell lines. GIRK1 protein was not expressed in MDA-MB435 cells, corresponding to the lack of mRNA expression in previous research. GIRK1 protein expression was seen in MDA-MB468 cells, however mRNA expression was lacking in our previous studies. To prove that the lower MW protein was GIRK1, MDA-MB453 and MDA-MB468 cells were immunoprecipitated, and then separated by western blotting. The specific band on these gels was at the lower MW. We believe this to be post-translational modification of the protein. This is the first report indicating GIRK protein expression in breast cancer cells. To determine functionality, MDA-MB453 cells were stimulated with ethanol, known to open GIRK channels. Increases in GIRK1 protein expression were seen after 30 minute treatment with 0.12% ethanol. In addition, serum-free media completely inhibited GIRK1 protein expression. Our data indicates that there are functional GIRK channels in breast cancer cells and these channels are involved in cellular signaling. Research supported by a grant from Philip Morris USA Inc. / Philip Morris International.

**Mechanisms of ATP Release in Human Airway Epithelial Cells**

N. Cheng,[1,2] E. M. Schwiebert[1,2]; [1]Department of Physiology and Biophysics and of Cell Biology, Univ. of Alabama at Birmingham, Birmingham, AL, [2]Gregory Fleming James Cystic Fibrosis Research Center, Univ. of Alabama at Birmingham, Birmingham, AL

Secreted ATP is an important autocrine and paracrine signaling molecule in most if not all cells and tissues. Nevertheless, the cellular and molecular mechanisms of ATP release are understood poorly. Putative mechanisms fall into two broad categories: ATP-filled vesicles and ATP transporters/ channels. In particular, ATP-permeable anion channels such as “maxi” or large conductance anion channels, voltage-dependant anion channels (VDAC), connexin or gap junction hemichannels, and the cystic fibrosis transmembrane conductance regulator (CFTR) anion channel. RNA interference is being used by our laboratory to assess the relative roles of the above anion channel candidates in flow-, mechanical-, calcium-, cyclic nucleotide-, and hypotonicity-induced ATP release. Low temperature- and tetanus toxin active fragment-induced block of vesicle trafficking and fusion is also used to assess the above. Taken together, we have identified roles for vesicle- and channel-mediated ATP secretion in basal and stimulated autocrine and paracrine purinergic signaling in airway epithelia. Future work seeks to identify the cellular mechanisms that remain intact in cystic fibrosis (CF) airway epithelia and participate in endogenous zinc and ATP co-secretion to stimulate apical P2X receptor channels independent or in addition to exogenously applied ligands.

399

**A Dynamic Role of Calbindin-D28K in TRPV5-Mediated Ca2+ Reabsorption**

T. T. Lambers,[1] F. Mahieu,[2] E. Oancea,[3] F. de Lange,[4] T. Voets,[2] D. Clapham,[3] B. Nilius,[2] J. G. Hoenderop,[1] R. J. Bindels[1]; [1]Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands, [2]Physiology, KU Leuven, Leuven, Belgium, [3]Cardiovascular Dept, Children's Hospital and Harvard Medical School, Boston, MA, [4]Celbiology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands

**Objectives;** TRPV5 and TRPV6 facilitate $Ca^{2+}$ influx in a variety of epithelial cells and are consistently co-expressed with the $Ca^{2+}$-binding proteins calbindin-$D_{9K}$ and/or -$D_{28K}$. Calbindins are thought to be involved in facilitated diffusion of $Ca^{2+}$ from the point of entry to the extrusion site, while simultaneously preventing cytotoxic high $Ca^{2+}$ levels. The aim of the present study was to investigate the role of calbindins in transepithelial $Ca^{2+}$ transport and their influence on the activity of TRPV5 and TRPV6. **Methods;** We investigated binding of calbindin-$D_{9K}$ and -

$D_{28K}$ with TRPV5/6 using pull-down and co-immunoprecipitation analysis. The translocation of calbindin-$D_{28K}$ towards the plasma membrane was assessed by cell fractionation techniques and Total Internal Reflection Fluorescent Microscopy (TIRFM). The functional effect of calbindins on TRPV5/6 activity was studied by $^{45}Ca^{2+}$ uptake and electrophysiological measurements. **Results;** TRPV5 associated with calbindin-$D_{28K}$ only when the intracellular $Ca^{2+}$ concentration was low due to BAPTA buffering. Furthermore, in the absence of $Ca^{2+}$ an increased calbindin-$D_{28K}$ abundance was detected in isolated plasma membranes. TIRFM revealed that calbindin-$D_{28K}$ translocates towards the plasma membrane when cells are treated with BAPTA-AM. $^{45}Ca^{2+}$ uptake in TRPV5-expressing MDCK cells was increased in the presence of calbindin-$D_{28K,}$ but not in the presence of a $Ca^{2+}$-insensitive calbindin-$D_{28K}$ mutant emphasizing the importance of the $Ca^{2+}$-binding EF-hand structures. The direct effect of calbindin-$D_{28K}$ on the activity of TRPV5 at a controlled $[Ca^{2+}]_i$ was investigated by uncaging $Ca^{2+}$ from the photolysable $Ca^{2+}$ chelator DMNP-EDTA. The $Ca^{2+}$-dependent inhibition of the TRPV5 current was similar in the presence of wild-type or $Ca^{2+}$-insensitive calbindin-$D_{28K}$. **Conclusions**; We propose a novel model in which translocation of calbindin-$D_{28K}$ towards the plasma membrane occurs at low intracellular $Ca^{2+}$ concentrations allowing association with TRPV5 to regulate the TRPV5 activity by buffering the local influx of $Ca^{2+}$.

### Recruitment of the Epithelial Ca2+ Channel TRPV5 to the Plasma Membrane is Dependent on Extracellular pH

T. T. Lambers,[1] E. Oancea,[2] D. Clapham,[2] J. G. Hoenderop,[1] R. J. Bindels[1]; [1]Physiology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands, [2]Cardiovascular Dept, Children's Hospital and Harvard Medical School, Boston, MA

**Objectives:** TRPV5, a member of the Transient Receptor Potential (TRP) superfamily is the gatekeeper facilitating $Ca^{2+}$ influx in epithelial cells of the kidney. A major physiological effect of extracellular pH is the regulation of membrane transport and regulation of renal $Ca^{2+}$ homeostasis. In the present study, we assessed whether the trafficking of TRPV5 is regulated by extracellular pH. **Methods:** Using Total Internal Reflection Fluorescent Microscopy (TIRFM) and biotinylation experiments the effect of extracellular pH on the recruitment of TRPV5 to the plasma membrane was investigated. After chemical bleaching with MTSET to irreversible inactivate membrane targeted TRPV5, the recovery was studied at different values of extracellular pH. The influence of extracellular pH on TRPV5-mediated $Ca^{2+}$ influx was investigated by $^{45}Ca^{2+}$ uptake experiments and modulators of vesicular trafficking were added during the uptake to provide insight into the mechanism of TRPV5 recruitment to the plasma membrane. **Results:** TRPV5-mediated $^{45}Ca^{2+}$ uptake was stimulated at an increased extracellular pH (pH 8.5), whereas at a decreased pH (pH 6.0) the TRPV5-mediated $^{45}Ca^{2+}$ uptake was diminished. An increase in extracellular pH resulted in a rapid and dramatically increased membrane-associated TRPV5-eGFP signal. Biotinylation experiments revealed that this rapid recruitment of intracellular TRPV5-containing vesicles led to insertion of active TRPV5 channels in the plasma membrane. Furthermore, the recovery after chemical bleaching with MTSET was elevated at alkali extracellular conditions. In addition, disruption of microtubules with nocodazole led to a decrease in the pH-stimulated TRPV5 mediated $^{45}Ca^{2+}$ uptake. **Conclusions:** pH-dependent recruitment of TRPV5 towards the plasma membrane is a novel way to regulate $Ca^{2+}$ transport in kidney and is dependent on microtubule mediated vesicular transport.

### Interleukin-1β Activates $Na^+$-$K^+$-$2Cl^-$ Cotransporter in Human Middle Ear Epithelia

J. Kim, J. Choi, J. Yoon, W. Namkung, E. Son, H. Park, M. Lee; College of Medicine Yonsei University, Seoul, Republic of Korea

Disruption of periciliary fluid homeostasis is the main pathogenesis of otitis media with effusion (OME), which is one of the most common childhood diseases. Although the underlying molecular mechanisms are unclear, it has been suggested that the altered functions of ion channels and transporters are involved in the fluid collection of middle ear cavity of OME patients. In the present study, we analyzed effects of the inflammatory cytokine IL-1ß on $Na^+$-$K^+$-$2Cl^-$- cotransporter 1 (NKCC1) in human middle ear cells. Intracellular pH ($pH_i$) were measured in primary cultures of normal human middle ear epithelial (NHMEE) cells using a double perfusion chamber, which enabled us to analyze membrane-specific transporter activities. NKCC activities were estimated by the $pH_i$ reduction due to bumetanide-sensitive intracellular uptake of $NH_4^+$. In addition, transepithelial fluid transport was measured with or without bumetanide-treatments. NKCC activities were observed in the basolateral membrane, but not in the luminal membrane of NHMEE cells. Correspondingly, immunoblotting of membrane-cultured NHMEE cells revealed the expression of NKCC1 on the basolateral membrane. Interestingly, IL-1ß treatments augmented the basolateral NKCC activities and increased NKCC1 expression. In addition, IL-1ß stimulated bumetanide-sensitive fluid transport in NHMEE cells. Furthermore, NKCC1 expression was increased in middle ear cells from the patients with OME when compared to samples from control individuals. The above results provide comprehensive evidence that the inflammatory cytokine IL-1β upregulates NKCC1 in the middle ear epithelial cells, which would be one of the important underlying mechanisms of fluid overcollection in patients with OME.

### Rapid Posttranslational Regulation of the Mouse Zinc Transporters ZIP4 and ZIP5 following Zinc Repletion

B. P. Weaver, G. K. Andrews; Biochemistry, KUMC, Kansas City, KS

ZIP4 and ZIP5 belong to the ZIP (Zrt-Irt-like proteins, SLC39A) family of metal ion transporters. Mutations in human ZIP4 cause acrodermatitis enteropathica which reflects an inability to absorb adequate zinc from the diet. ZIP5 is a close paralog to ZIP4. We have shown that both transporters undergo differential trafficking in response to dietary zinc depletion. To further examine the mechanism of regulation for ZIP4 and ZIP5, we analyzed proximal intestine and pancreas from weanling mice fed a zinc deficient (ZnD) or zinc adequate (ZnA) diet for 10 days followed by a gavage of zinc (or saline control). Tissues were collected for up to 6h after gavage (n = 4 for each group). Intestinal MT-I mRNA was upregulated after the zinc gavage. In contrast, intestinal ZIP4 mRNA was induced during ZnD but remained unchanged after zinc gavage and ZIP5 mRNA was unaltered by zinc. In mice fed a ZnA diet, ZIP4 protein was rare and was not detected on the apical membrane of enterocytes, whereas ZIP5 protein was detected on basolateral membranes of enterocytes and pancreatic acinar cells. During ZnD, ZIP4 protein accumulated at the apical membrane of enterocytes while ZIP5 was removed from the enterocytes and acinar cell membranes. Within 4h of a zinc gavage, ZIP4 protein was internalized and rapidly degraded in enterocytes whereas ZIP5 protein re-accumulated on the basolateral membranes of enterocytes and acinar cells. These effects were protein-specific since other apical and basolateral membrane proteins were unaffected by zinc and these effects were cell-specific since ZIP4 protein abundance in beta-cells was apparently unaffected by zinc.

**Characterizing Membrane Potential Changes during Ascidian Sperm Activation**

R. McNulty, R. A. Koch; Biological Science, CSU Fullerton, Fullerton, CA

Contact, both direct and indirect, between sperm and egg initiate cell signaling pathways that trigger internal responses. In the sea squirt sperm cells, these responses include increased swimming activity and mitochondrial translocation, an actin:myosin-dependent process that allows the sperm to penetrate the egg. Our laboratory has studied the latter response in *Ascidia ceratodes* and shown that calcium influx via penfluridol-sensitive channels is necessary for mitochondrial translocation. Thus, we have investigated the role of membrane potential change in sperm activation. We used the voltage-sensitive dye, DiS-C(3)5, to measure changes in sperm membrane potential in batches of sperm. The contribution of the mitochondrial potential was eliminated with FCCP. The artificial stimulus of high external pH induced a rapid hyperpolarization with a subsequent slow return to near resting potential. Experiments that varied external potassium ion concentrations ($[K^+]_o$) support a significant role for $K^+$ efflux in hyperpolarization. Reversal potential determined from this data predict an internal $[K^+]$ of 105mM. Stepwise addition of $K^+$, in presence of valinomycin, allowed the determination of a resting membrane potential of -40mV and a $K^+$ equilibrium potential of -62mV. Since high pH leads to hyperpolarizing membrane potentials around -250mV, it is likely the hyperpolarization results from multiple components. The potential role of $Cl^-$ influx in pH-induced hyperpolarization was also investigated by ion substitution with sodium gluconate. Decreasing $[Cl^-]_o$ decreased amplitude of hyperpolarization, until 100mM. The hyperpolarization was blocked with furosemide, supporting the involvement of inward rectifying K channels or chloride-permeable GABA-A ligand-gated channels. Hyperpolarization was also blocked with penfluridol and pimozide, supporting the idea calcium influx via T-type $Ca^{2+}$ channels precedes $K^+$-dependent hyperpolarization. We conclude pH-induced hyperpolarization depends on $K^+$ efflux and $Cl^-$ influx. Studies are under way to classify channels responsible for hyperpolarization and their relationship to calcium influx.

**Expression of $B^0AT1$ and LAT2 Amino Acid Transporters in Spontaneous Hypertensive Rat on High Salt Intake**

M. Pinho, P. Soares-da-Silva; Inst. Pharmacol. Ther., Faculty of Medicine, Porto, Portugal

The present study evaluated the activity of renal dopaminergic system and the expression of LAT2, 4F2hc and $B^0AT1$ in the renal cortex of the SHR and the normotensive Wistar-Kyoto rats (WKY), during normal (NS) and high (HS) salt intake. At 12 weeks of age, WKY failed to respond to HS with increases in the urinary dopamine excretion, while HS intake in SHR produced a marked increase in the urinary excretion of dopamine. L-DOPA plasma levels in SHR during NS and HS intake were similar to those in WKY. RT-PCR quantification analysis revealed a decreased expression of LAT2 mRNA in WKY and SHR on HS intake. At 12 weeks of age, LAT2/4F2hc ratios in SHR on HS intake were significantly lower (18 % reduction) than in SHR fed a NS diet, which was not the case in WKY. This suggested that a $Na^+$ dependent transport system may be promoting the L-DOPA uptake, this being most prominent in the SHR. Evaluation of the expression of $Na^+$ dependent $B^0AT1$, showed a significant decrease in both 4 and 12 week old WKY and in 4 week old SHR, fed HS diet. By contrast, HS intake produced a significant increase (~ 45% augment) in $B^0AT1$ mRNA of SHR of 12 weeks of age. It is concluded that increased renal dopamine production and excretion in SHR might be related to enhanced ability to take up L-DOPA at the kidney level. During HS, $Na^+$ dependent $B^0AT1$ is overexpressed in SHR kidney, probably contributing to the enhanced L-DOPA uptake, observed in the hypertensive phase. Differences in regulation of renal $B^0AT1$ and LAT2 in SHR versus WKY may have to do with differences concerning sodium handling. Supported by grant POCTI/SAU-OBS/57916/2004

**Cloning and Expression of Rat Neutral Amino Acid Transporter $B^0AT1$ (SLC6A19) in Renal Tissues**

M. Pinho, P. Soares-da-Silva; Inst. Pharmacol. Ther., Faculty of Medicine, Porto, Portugal

$B^0AT1$ is a novel member of the $Na^+$ dependent neurotransmitter transporter family (SLC6), and a candidate gene for the Hartnup disorder. Here, it is reported the cloning and molecular characterization of neutral amino acid transporter $B^0AT1$ in the rat kidney. A homology search was performed using BLASTN 2.2.5 (NCBI) and *Mus musculus* $B^0AT1$ sequence (XM_127449) against the non-redundant and EST databases. Three Rattus norvegicus putative $B^0AT1$ sequences were found on the EST database. The most significant being CK474548 with 834 nucleotides and CK473544 with 790 nucleotides, both belong to a cDNA library, which RNA was obtained from rat kidney. Identity of 90% and 93% were found between the mouse $B^0AT1$ and rat CK474548 and CK473544 sequences, respectively. Sets of primers were designed based on the alignments between known sequences. PCR and 5' RACE were performed using cDNA obtained from total RNA from kidney cortex of WKY rat. Fragments obtained were cloned and sequencing. The sequence obtained for rattus norvegicus $B^0AT1$ transcript has 2360 bp, and alignments with human and mouse homologues revealed identities of 84.4% and 94.3%, respectively. The expression of $B^0AT1$ transcript was also examined by RT-PCR using specific primers in SHR and WKY immortalized renal proximal tubular epithelial cells, both cell lines amplified the expected product of 1026 bp. Supported by grant POCTI/SAU-OBS/57916/2004.

**Functional Characterization of $Na^+$-$HCO_3^-$ Cotransporter in WKY and SHR Proximal Tubular Epithelial Cells**

R. Pedrosa, N. Gonçalves, P. Soares-da-Silva; Inst. Pharmacol. Ther., Faculty of Medicine, Porto, Portugal

The present study was designed to evaluate the presence and characterize the functional proprieties of the $Na^+/HCO_3^-$ cotransporter in immortalized proximal tubular epithelial cells from spontaneous hypertensive rat (SHR) and their normotensive controls (Wistar Kyoto rats; WKY). The $Na^+$-$HCO_3^-$ cotransporter activity was assayed as the initial rate of the $Na^+$-dependent $pH_i$ recovery ($dpH_i/dt$, pH/s) in a $HCO_3^-$ containing solution after an acid load induced by $NH_4^+$ (20 mM) in the absence of $Na^+$. After intracellular acidification and in the presence of amiloride (1 mM), the addition of $Na^+$ (115 mM) in the absence of $Cl^-$ resulted in rapid pHi recovery in both WKY (0.00227 ± 0.00019 pH units/s) and SHR (0.00168 ± 0.00012 pH units/s) cells. This recovery was clearly $Na^+$ and $HCO_3^-$ dependent in both WKY and SHR cells. DIDS (4,4'-diisothiocyanatodihydrostilbene-2,2'-disulphonic acid; 300 µM) markedly inhibited the $Na^+$ and $HCO_3^-$-dependent pHi recovery phase. Taken together these results suggest that WKY cells and SHR cells are endowed with a $Na^+$-$HCO_3^-$ cotransporter. Chronic acidosis induced by 24 h treatment with $NH_4^+$ (20 mM) increased $Na^+$-$HCO_3^-$ cotransport activity that was greater in SHR cells (79.8 ± 13.3 % increase) than in WKY cells (37.7 ± 2.9 % increase), with no changes in intracellular pH and cell viability (93.8 ± 2.4 and 99.4 ± 1.4 % of live cells; WKY and SHR). Treatment with acetozalamide (300 µM) for 24 h

did not change the $Na^+$-$HCO_3^-$ activity in WKY and SHR cells. It is concluded that the activity of the $Na^+$-$HCO_3^-$ cotransporter in SHR cells was lower than that in WKY, but the former responds with an enhanced response to acidosis-induced stimulation of $Na^+$-$HCO_3^-$ activity. Supported by grant POCTI/SAU-FCF/59207/2004.

**Enhanced Sensitivity to Angiotensin II-induced Stimulation of $Cl^-/HCO_3^-$ Exchanger in Immortalized SHR Proximal Tubular Epithelial Cells**

R. Pedrosa, P. Soares-da-Silva; Inst. Pharmacol. Ther., Faculty of Medicine, Porto, Portugal

We have recently reported an increased activity of the apical $Cl^-/HCO_3^-$ exchanger (SLC26A6) in immortalized proximal tubular epithelial cells from spontaneous hypertensive rat (SHR) when compared with their normotensive controls (Wistar Kyoto rats; WKY). The present study evaluated the expression and function of SLC26A6 after angiotensin II (Ang II) in immortalized proximal tubular epithelial cells from SHR and WKY. The expression of SLC26A6 in SHR cells was 7 fold (704.0±115.2 %) that in WKY cells. The exposure of cells to Ang II for 25 min induced an increase in SLC26A6 activity with an $EC_{50}$ value of 0.10 (0.05, 0.22) nM and 11.85 (7.63, 18.39) nM in SHR and WKY cells, respectively. An equipotent stimulatory effect induced by 1 nM Ang II (178.4±14.4 % stimulation) in SHR cells and 30 nM Ang II (175.7 ± 25.0 % stimulation) upon SLC26A6 was completely blocked by losartan (100 nM) in both cell types. By contrast, the effect of Ang II was unaffected by the specific AT2 antagonist PD 123,319 (100 nM). A short treatment (5 min) with Ang II (10 nM) induced an increase in SLC26A6 activity in SHR cells, but not in WKY cells. These effects were antagonized by losartan (100 nM) but not by PD 123,319 (100 nM). It is concluded that SHR cells have an increased activity of SLC26A6, as a result of the higher expression of this transporter. SHR cells also have an enhanced sensitivity to Ang II-induced stimulation of the $Cl^-/HCO_3^-$ exchanger activity through the AT1 receptor. Supported by grant POCTI/SAU-FCF/59207/2004.

**KCl Cotransport is Essential for Insulin-like Growth Factor 1-mediated Invasiveness and Proliferation of Breast Cancer Cells**

M. Shen; Department of Pharmacology, National Cheng Kung University, College of Medicine, Taiwan, Taiwan Republic of China

Electroneutral K-Cl cotransport (KCC), via the regulation of ionic and osmotic homeostasis, has begun to emerge of its important roles in cancer development, tumor invasion, and possibly metastasis. We test the hypothesis that insulin-like growth factor 1 (IGF-1) may promote breast cancer development and progression through its action on KCC. IGF-1 enhanced KCC-dependent cell volume regulation. IGF-1 treatment triggered phosphatidylinositol 3-kinase and mitogen-activated protein kinase cascades which were differentially required for IGF-1-stimulated biosynthesis of KCC. IGF-1 dose-dependently stimulated cellular invasiveness and proliferation, which were almost abolished by KCC inhibitor. The invasiveness and proliferation of KCC dominant-negative mutant cells were insensitive to IGF-1 stimulation. KCC mutation significantly decreased xenograft tumor size in SCID mice although the phosphorylation of IGF-1 receptor was not changed. In addition to colocalization, the expression level of IGF-1 and KCC in the same surgical specimen showed a good linear correlation, suggesting autocrine or paracrine IGF-1 stimulation of KCC production *in vivo*. Among patients with early-stage node-negative breast cancer, disease-free and overall survival curves were significantly different based on IGF-1 and KCC expression. Thus, we conclude that KCC activation by IGF-1 plays an important role in IGF-1 signaling to promote growth and spread of breast cancer cells.

**Interaction of Cation Channel TRPV4 and Actin Cytoskeleton**

D. Becker, R. Ramadass, C. Blase, M. Jendrach, J. Bereiter-Hahn; Kinematic Cell Research Group, Biocenter Frankfurt University, Frankfurt, Germany

The non-selective cation channel TRPV4 is involved in many different physiological processes like osmoregulation and temperature sensing. We investigated activation mechanism of TRPV4 in response to hypotonic stress using $Ca^{2+}$ imaging and fluorescence lifetime imaging microscopy (FLIM). Under hypotonic conditions TRPV4 is activated and permeable to $Ca^{2+}$ ions, which leads to a transient $[Ca^{2+}]_i$ increase. The hypotonicity induced $[Ca^{2+}]_i$ increase was abolished in cells treated with F-actin disrupting reagents. Confocal laser scanning microscopy (CLSM) of phalloidin stained and GFP-TRPV4 transfected cells showed co-localisation in plasma membrane. To evaluate interaction, fluorescence resonance energy transfer (FRET) studies, using picosecond FLIM were performed. CFP-TRPV4 and YFP-actin double transfected CHO cells were observed with a fluorescence decay microscope, calibrated with a full width at half maximum (FWHM) of 75 ps for the temporal resolution. CFP-TRPV4 was excited at 440nm and fluorescence decays, both spectrally and spatially resolved, were obtained. In CFP-TRPV4 and YFP-actin double transfected cells, the lifetime of the fluorescence decay obtained at 470-480nm was around 40% reduced in the shorter lifetime, compared to CFP-TRPV4 single transfected cells. Also, in the case of spectrally resolved fluorescence decays an emission peak corresponding to YFP fluorescence at 530nm was seen. Taken together, these results indicate close proximity and interaction of TRPV4 and actin cytoskeleton.

410

**Nedd4-2-mediated Ubiquitination and Degradation of ENaC**

R. Zhou, P. M. Snyder; Internal Medicine, Physiology and Biophysics, University of Iowa, Iowa City, IA

The epithelial Na+ channel (ENaC) is an amiloride-sensitive ion channel composed of three subunits (alpha, beta, and gamma ENaC) that plays a critical role in Na+ homeostasis and blood pressure control. ENaC is regulated by Nedd4-2, an E3 ubiquitin-protein ligase. Here we tested the hypothesis that Nedd4-2 inhibits ENaC by ubiquitination of ENaC subunits. We found that Nedd4-2 induced ubiquitination of all three subunits either in the total protein pool or at cell surface. Nedd4-2 binds to cell surface ENaC followed by ubiquitination, which had a selective effect on the pool of ENaC at the cell surface; using a biotinylation assay, we found that Nedd4-2 produced a dose-dependent decrease in ENaC at the cell surface, but had no effect on the cytoplasmic pool of ENaC. Nedd4-2 decreased ENaC surface expression by increasing the rate of degradation of cell surface ENaC. Mutation of a cysteine in the Nedd4-2 HECT domain required for ubiquitin ligase activity abolished the ability of Nedd4-2 to decrease ENaC surface expression and catalyze ENaC ubiquitination. The Nedd4-2-mediated decrease in ENaC surface expression and increase in ENaC ubiquitination were also abolished or attenuated by mutations in ENaC PY motifs (that cause Liddle's syndrome) or Nedd4-2 WW domains which mediate binding to ENaC. We found that SGK and PKA blunted the ability of Nedd4-2 to decrease ENaC surface expression. Conversely,

mutation of the Nedd4-2 phosphorylation sites increased ENaC degradation. Together the data suggest that Nedd4-2 modulates epithelial Na+ transport by ubiquitination of ENaC, which selectively targets ENaC at the cell surface for degradation. Nedd4-2-mediated degradation is regulated by SGK and PKA, down-stream mediators of the aldosterone and vasopressin pathways. Defects in this regulation are responsible for Liddle's syndrome, an inherited form of hypertension, and could contribute to the pathogenesis of essential hypertension.

**Soluble Interaction Domains in hERG1a/1b Heteromeric Channels**

P. Phartiyal, E. M. C. Jones, G. A. Robertson; Physiology, University of Wisconsin-Madison, Madison, WI

Channels producing $I_{Kr}$ currents in the human heart are composed of two subunit species encoded by alternate transcripts of the *human Ether-a-go-go-Related Gene* (*hERG*), but the mechanisms regulating channel assembly and composition are unknown. In heterologous expression systems, the two subunits readily assemble to produce heteromeric channels with robust currents. When expressed in isolation, hERG1a also produces large currents but hERG1b produces little or no current. hERG1a and hERG1b subunits are identical except for the N termini, which are largely unique. Previous studies have shown subunit assembly of Kv channels progresses cotranslationally, with specificity determined by the association of nascent N termini emerging from the ribosome. We tested the hypothesis that hERG 1a and 1b N termini interact to promote heteromeric assembly of hERG subunits. We also tested the hypothesis that hERG1b subunits fail to assemble homotypically owing to electrostatic repulsion between N termini bearing a net positive charge. We found the hERG1a and 1b N termini have a direct and dose-dependent interaction as assayed by GST fusion protein interactions. In addition to the N-N interactions, association between the N and C termini was also observed to be robust and dose-dependent. However, 1a and 1b subunits with nearly complete C-terminal truncations coexpressed in HEK-293 cells were able to assemble, indicating heteromerization does not depend on the presence of the C terminus. Surprisingly, 1b subunits were also shown to interact homotypically as assayed by co-immunoprecipitation experiments, indicating that low 1b current density is not attributable to N-terminal repulsion and failed assembly. Results from this study identify key soluble interaction domains involved in hERG heteromerization and present the first step toward dissecting the assembly process of this important heteromeric potassium channel. Supported by NIH grant HL68868.

**Endothelin-1 Regulation of Caveolar $Ca_v1.2$ Channel Function Involves a Multiprotein Signaling Complex Including Non-Receptor Tyrosin Kinases in Cardiac Myocytes**

R. C. Balijepalli,[1] J. D. Foell,[1] K. Y. Chung,[2] J. L. Walker,[2] T. J. Kamp[1]; [1]Medicine, University of Wisconsin, Madison, Madison, WI, [2]Physiology, University of Wisconsin, Madison, Madison, WI

Endothelin-1 regulation of cardiac function is in part due to the stimulation of influx of $Ca^{2+}$ through L-type $Ca^{2+}$ channels in ventricular cardiomyocytes. Previously we have demonstrated the localization of L-type $Ca^{2+}$ ($Ca_v1.2$) channels and endothelin-A receptors ($ET_AR$) in caveolar microdomains in ventricular myocytes. However, the critical intermediate proteins in the signaling cascade linking $ET_AR$ and regulation of $Ca_v1.2$ channels have not been described in detail. We utilized immunoprecipitation (IP) and proteomics approaches to characterize the signaling complexes associated with $ET_AR$ and $Ca_v1.2$ channels in caveolae. $Ca_v1.2$, caveolin-3 and $ET_A$-receptor were separately immunoprecipitated from mouse ventricular homogenates using respective specific antibodies, and associated proteins were resolved on SDS-PAGE gels. Trypsin and Glu-C digested peptide masses were subjected to MALDI-TOF mass-spectrometry and Swiss-Prot database analysis. Proteomic analysis of the three IPs revealed significant overlap of constituent proteins including membrane receptor proteins, ion channels, cytoskeletal proteins, trafficking proteins and kinases such as non-receptor tyrosine kinases including Pyk2 and c-Src. To specifically investigate the role of non-receptor tyrosine kinases in the functional regulation of $Ca_v1.2$ channels, we performed whole-cell patch clamp experiments in neonatal mouse ventricular myocytes. ET-1 (100 nmol/L) stimulation of ventricular myocytes significantly increased $I_{Ca,L}$ by 59±16% (n=3, $p<0.05$), and this ET-1 effect was abolished by pretreatment of cells with tyrosine kinase inhibitors genistein (50µM) and c-src inhibitor PP2 (50µM). In addition, ET-1 induced Tyr-phosphorylation of the $Ca_v1.2$ channel, which was blocked by pretreatment with genistein or PP2. We conclude that non-receptor tyrosine kinases as part of a macromolecular signaling complex are essential in mediating the ET-1 regulation of $I_{Ca,L}$. Understanding the details of this signaling pathway may provide new insights into the regulation of heart function in health and disease.

413

**hERG-RUFY2 Interactions in the Endocytic Pathway**

S. A. Delfosse, E. C. Roti Roti, E. M. C. Jones, G. A. Robertson; Dept. of Physiology, University of Wisconsin-Madison, Madison, WI

Cardiac excitability is determined not only by the types of ion channels present in the surface membrane but also by their relative densities. One mechanism important in regulating surface channel density is endocytosis, a first step in both degradation pathways and recycling. In searching for proteins involved in hERG channel trafficking, we identified RUFY2 in a yeast two-hybrid screen of a human heart library using the hERG C terminus as bait. RUFY2 is homologous to the RUFY1 rab4-interacting protein implicated in the recycling endosomal pathway. Antibodies raised specifically against RUFY2 identified a 75 kD protein in human heart lysate. Subcellular fractionation of HEK-293 revealed colocalization of hERG with RUFY2 in endosomal fractions verified by the presence of EEA1, an early endosomal marker. hERG and RUFY2 also had overlapping distributions in sub-plasma membrane compartments as demonstrated by immunocytochemistry. These findings are consistent with a role for RUFY2 in hERG trafficking, possibly by regulating surface expression via channel turnover and/or recycling. Supported by NIH grant HL68868.

414

**GM130 Sorts hERG Channels Based on Subunit Composition**

E. C. Roti Roti, E. M. C. Jones, G. A. Robertson; Dept. of Physiology, University of Wisconsin-Madison, Madison, WI

*hERG*, the *human Ether-a-go-go-Related Gene*, encodes a voltage-gated potassium channel expressed as two isoforms, 1a and 1b, which coassemble to form heteromeric channels underlying cardiac $I_{Kr}$ (Jones et al JBC 279:44690, 2004). $I_{Kr}$ can be disrupted by inherited mutations, giving rise to long QT syndrome (LQTS) and potentially fatal cardiac arrhythmias. Most mutations characterized to date disrupt trafficking of hERG channels, but the underlying molecular mechanisms are poorly understood. We are characterizing hERG-interacting proteins in an effort to elucidate steps in the trafficking pathway that regulate surface expression and to identify potential targets for disease. We previously showed that

GM130, a *cis*-Golgi matrix protein involved in vesicular transport between the ER and Golgi, also interacts with hERG as a cargo molecule (Roti Roti et al JBC 277:47779, 2002). We tested the hypothesis that GM130 is responsible for sorting 1a homomers and 1a/1b heteromers, which traffic effectively to the plasma membrane, from 1b homomers, which do not. In binding assays, GM130 showed a strongly preferential interaction with hERG 1b homomers. Consistent with the binding data, hERG 1b homomers accumulated in Golgi compartments. These data suggest GM130 sorts hERG oligomers for surface expression based on subunit composition. Supported by NIH grant HL68868 (GAR) and NIH NRSA T32 HL07936 from the University of Wisconsin-Madison Cardiovascular Research Center (ECRR).

**Direct Phosphorylation of a Voltage-Gated Potassium Channel by PKA Modulates its Expression on the Cell Surface**

E. C. Connors, A. D. Morielli; Pharmacology, University of Vermont, Burlington, VT

Trafficking of ion channels to and from the cell surface is crucial for regulation of membrane potential and is often controlled by direct phosphorylation of the channel protein. The voltage-gated potassium channel Kv1.2 has been shown to be negatively regulated by tyrosine phosphorylation and subsequent trafficking away from the plasma membrane through endocytosis. In this study, we investigate mechanisms for positive regulation of the channel through phosphorylation by protein kinase A (PKA). Using flow cytometry to quantify the level of Kv1.2 on the cell surface, we found that a 10 minute application of 10μM forskolin, increased the amount of Kv1.2 on the cell surface by 54.01 +/- 0.06% (p=8E-05; n=53). Inhibitors of PKA, KT5720 (5μM; p=0.22; n=20) and PKI (p=0.20; n=3), but not a mutant form of PKI that does not bind the catalytic subunit of PKA (p=0.004; n=3), blocked the response. Previous electrophysiology data had shown that a mutation within the N-terminus of the channel, threonine 46 to valine (T46V), blocked channel potentiation via PKA. T46V channels are also resistant to forskolin-induced increases of Kv1.2 levels at the cell surface (p=0.488; n=9). This data indicates that PKA mediated potentiation of the Kv1.2 ionic current occurs in part by increasing the quantity of Kv1.2 channels expressed at the surface of the cell.

416

**Activation of 5-$HT_{2B}$ Receptor Stimulates $Ca^{2+}$ Influx through TRPC6 Channels in Pelvic Autonomic Transmission**

S. Cha, I. Kong; Department of Physiology, Yonsei Univ. College of Medicine, Wonju, Republic of Korea

Pelvic ganglia provide autonomic innervations to the various pelvic organs such as colon, bladder and penis. Several studies have shown that 5-HT is present in some neurons of the pelvic ganglia, depolarizes neurons and inhibits ganglion transmission. In pelvic ganglia, however, mechanisms underlying actions of 5-HT remain unknown. We examined the role of 5-$HT_2$ receptor in pelvic autonomic transmission using patch-clamp and fluorescence $Ca^{2+}$ measurement techniques. In both sympathetic and parasympathetic neurons, 5-HT (10 μM) itself and BW723C86 (10 μM), a 5-$HT_{2B}$ agonist, increased $[Ca^{2+}]_i$ , which were prevented by SB204741 (10 μM), a 5-$HT_{2B}$ antagonist. This 5-$HT_{2B}$-mediated $[Ca^{2+}]_i$ increase was blocked by removal of extracellular $Ca^{2+}$, by nonselective cation channel blockers, $Gd^{3+}$ (10 μM) or $La^{3+}$ (100 μM), and by U73122 (1 μM), a PLC inhibitor with no effect of U73343 (1 μM), an inactive analogue of PLC. Under a voltage-clamp condition, BW723C86 (100 μM) also caused an inward current in a $La^{3+}$-sensitive manner. Interestingly, OAG (100 μM), a membrane permeable DAG analogue, induced $Ca^{2+}$ influx. RT-PCR analysis confirmed TRPC1 and TRPC6 expressed in MPG neurons. Taken together, these data suggest that $Ca^{2+}$ influx occurs through TRPC6 channels when activation of 5-$HT_{2B}$ receptors stimulates the $G_q$-PLC-DAG pathway.

417

**Membrane Targeting of Voltage-Gated Sodium Channel $Na_v1.6$**

A. Lee, A. L. Goldin; Microbiology & Molecular Genetics, University of California, Irvine, Irvine, CA

Voltage-gated sodium channels are membrane proteins that initiate action potentials in neurons following membrane depolarization. Members of this family show differential distribution at the subcellular level. The mechanisms underlying the targeting of these isoforms are not understood. However, their specificity is important because the isoforms can change the excitability of the membrane due to differences in their electrogenic properties. In this study, we examined the $Na_v1.6$ structure for a localization determinant. $Na_v1.6$ is the major isoform found at nodes of Ranvier. Using a fluorescent tag, we showed that $Na_v1.6$ segregated to the basolateral membrane domain of a polarized renal epithelial (MDCK) cell. In contrast, $Na_v1.2$--another major isoform found in the axon--appeared in the apical membrane domain. Chimeric constructs helped to narrow down the $Na_v1.6$ targeting signal to a 200 amino acid sequence region. Mutations within this region prevented $Na_v1.6$ from accumulating in the basolateral membrane. These results suggest that the $Na_v1.6$ channel carries a membrane-sorting signal within this sequence region and raise the probability that the region also plays a role in the nodal targeting of the $Na_v1.6$ channel in the neuron. The targeting effect of this sequence in neurons is currently under investigation.

418

**Post-transcriptional Regulation of Multidrug Resistant Efflux Pumps in Bacteria**

K. A. Gibbs, J. A. Theriot; Biochemistry Department, Stanford University, Stanford, CA

Resistance to toxins is crucial for the survival of all cells. In addition to toxin-specific mechanisms of resistance attained through transcriptional and translational regulation of specific enzymes, both eukaryotes and prokaryotes employ general integral membrane pumps to efflux small metabolites from the inside of the cell. Bacteria, in addition to fungi and other eukaryotes, encode membrane pumps that are able to export a range of antibiotics from different classes. These multidrug resistant (MDR) efflux pumps are increasingly found to be elevated in clinically isolated drug-resistant strains of pathogenic bacteria including *Escherichia coli* and *Pseudomonas aeruginosa*. We have identified a novel mechanism by which these efflux pumps are able to provide increased survival on acute exposure to antibiotics. We have engineered a plasmid encoding the MDR pump, MdfA, fused to Green Fluorescent Protein (GFP) under the control of the *lac* promoter. Wild-type MdfA is present on the chromosome. Cells carrying the MdfA-GFP transgene are able to continue to proliferate in concentrations of tetracycline and ampicillin bacteriostatic to wild-type *E. coli*. Strikingly, these cells express MdfA-GFP when exposed to tetracycline and ampicillin even in the absence of IPTG induction. In the absence of antibiotics, these same uninduced cells exhibit no fluorescence. Since the MdfA-GFP transgene is under the control of the *lac* promoter, it is unlikely that antibiotic exposure is regulating protein expression at the level of transcription. We propose that small metabolites, such as antibiotics, are able to regulate the expression or stability of MDR efflux pumps by directly stabilizing the protein. This effect may contribute to the

increased survival of bacteria, and perhaps eukaryotic cells, when exposed to antibiotics and other toxic small metabolites.

## Membrane Fusion (419-427)

419

### Efficient SNARE Mediated Fusion Requires Asymetric Phopholipid Distribution

J. A. Vicogne, D. Vollenweider, J. R. Smith, J. E. Pessin; Pharmacology, SUNY Stony Brook, Stony Brook, NY

GLUT4 transport vesicle fusion with the plasma membrane requires the plasma membrane t-SNAREs (Syntaxin 4 and SNAP23) and the vesicle v-SNARE (VAMP2). Although extensive studies have demonstrated that in vitro the neuronal t-SNAREs Syntaxin1/SNAP25 and the v-SNARE VAMP2 can function as the “minimal machinery” for the membrane fusion reaction, there have been no studies examining the functional properties of the GLUT4 SNARE proteins. Using proteoliposomes containing Syntaxin 4/SNAP23 and proteoliposomes containing VAMP2, we demonstrated that these SNAREs are capable of driving vesicle fusion with a similar rate and extent as the neuronal SNAREs. Moreover, reconstitution of the t-SNARE proteoliposomes with phosphatidic acid (PA) markedly enhanced the rate of the fusion reaction whereas reconstitution of the VAMP2 proteoliposomes with phosphatidic acid markedly reduced the rate of vesicle fusion. In contrast, reconstitution of the VAMP2 proteoliposomes with phosphatidylinositol-4,5-P2 (PIP2) increased vesicle fusion whereas PIP2 in the Syntaxin4/SNAP23 proteoliposomes inhibited vesicle fusion. Since PA potentiates negative membrane curvature and PIP2 supports positive membrane curvature, these data suggests that there is an inherent asymmetry in SNARE-mediated fusion reaction. We conclude that the rate of fusion can be regulated by membrane lipid composition probably by facilitating the action of SNAREs to open the fusion pore.

420

### SNARE Trans-Membrane Domains Regulate the Progression of Hemifused Yeast Vacuoles to Full Fusion

Y. Jun, W. Wickner; Biochemistry, Dartmouth College, Hanover, NH

While influenza HA-mediated membrane fusion fusion proceeds through a hemifusion intermediate, it remains yet to be determined whether Rab- and SNARE-mediated intracellular membrane fusion entails a hemifusion state. During the docking which preceeds yeast vacuole fusion, a ring of fusion factors surround disc-like apposed "boundary membrane" domains from each vacuole. As for lipid-anchored HA protein, lipid-anchored SNAREs support trans-SNARE pairing and lipid mixing but not content mixing. The full fusion of vacuoles with lipid-anchored SNARE can be achieved by modifying the curvature of inner membrane leaflet with membrane-permeable amphiphiles. These results suggest that Rab- and SNARE-mediated membrane fusion proceeds through a hemifusion intermediate and that the transmembrane domain of SNARE is important for progression to full fusion. We propose that the boundary membrane is a novel vertex ring hemifusion diaphragm of two bilayer membranes. This model explains the abundance of vacuole proteins and exterior leaflet lipids in the boundary membrane, as well as the generation of lumenal vesicles upon membrane fusion.

### A Dominant Negative Version of Vps45p Reveals Two Modes of Binding to its Cognate SNAREs

L. N. Carpp,[1] L. F. Ciufo,[2] S. G. Shanks,[1] A. Boyd,[2] N. J. Bryant[1]; [1]Division of Biochemistry and Molecular Biology, Institute of Biomedical and Life Sciences, University of Glasgow, Glasgow, United Kingdom, [2]School of Biomedical Sciences, The Physiological Laboratory, University of Liverpool, Liverpool, United Kingdom

Sec1/Munc18 (SM) proteins have been shown to be essential in SNARE mediated membrane fusion events. Their exact mode of action remains elusive. Crystal structures of two SM proteins with their cognate Syntaxins have been solved. Munc18a and Sly1p (involved in synaptic transmission and ER-to-Golgi transport, respectively) are both arch shaped molecules with a central cavity. Syntaxin1a sits in the central cavity of Munc18a and makes multiple contacts with the SM protein. The binding of Sly1p to Sed5p (Syntaxin5) is quite distinct from this and involves a hydrophobic pocket on the outer face of the SM protein. This binding is facilitated by a short peptide at the extreme N-terminus of the Syntaxin. We have previously demonstrated that the SM protein Vps45p binds to both its monomeric Syntaxin, Tlg2p, and also to Tlg2p-containing *cis*-SNARE complexes. We have now isolated a dominant-negative version of Vps45p that has enabled us to obtain data supporting a model in which Vps45p binds to Tlg2p, not only via a mode analogous to that described for Sly1p/Sed5p, but also by a distinct mode. Implications of this model for SM protein function will be discussed

422

### Purification, Activity Assay, and Phosphoinositide Binding of the HOPS/Class C Vps Complex

C. Stroupe; Dept. of Biochemistry, Dartmouth Medical School, Hanover, NH

The mechanisms by which Rab GTPase activation is coupled to SNARE complex assembly are unclear. The HOPS/Class C Vps complex is a nucleotide exchange factor and an effector for the vacuolar Rab protein Ypt7p, and is also required for formation of vacuolar SNARE complexes. We have developed a purification method and an activity assay for the HOPS complex. Using pure, active HOPS, we have found that the HOPS complex is required for vacuole tethering and for catalysts of vacuole docking to complete their functions during vacuole fusion. We have also shown that the HOPS complex binds specifically and directly to phosphoinositides. Phosphoinositide binding is required for vacuolar association of the HOPS complex and for its localization in the same membrane microdomains on docked vacuoles as Ypt7p and SNARE proteins. Concentration of the HOPS complex in these microdomains may be a key factor for its activity in linking active Ypt7p to SNARE complex assembly.

423

### The Lgl Proteins Interact with the Exocyst Complex and Regulate Exocytosis and Cell Polarization

X. Zhang, P. Wang, W. Guo; Department of Biology, University of Pennsylvania, Philadelphia, PA

The exocyst is a multiprotein complex essential for tethering post-Golgi secretory vesicles at specific domains of the plasma membrane for exocytosis. The exocyst functions upstream of the SNAREs, and regulates SNARE assembly and subsequent membrane fusion. However, how the exocyst interacts and regulates the SNAREs is unclear. Here we report that Exo84p, a component of the exocyst complex, directly interacts with the Lgl proteins, Sro7p and Sro77p, which also bind to the t-SNAREs. Disruption of the interaction between the exocyst and Sro7/77p results in

defects in post-Golgi secretion. Genetic analyses of an array of post-Golgi secretory mutants demonstrate a molecular pathway from the Rab and Rho GTPases, through the exocyst and Lgl, to the SNAREs. We also found that overexpression of Lgl and the t-SNARE protein not only improves exocytosis but also rescues the polarity defects in exocyst mutants. We propose that Lgl proteins play an important role in promoting the coupling between the vesicle tethering machinery (the exocyst) and the fusion machinery (the SNAREs). Although Lgl is broadly distributed in the cells, its localized interaction with the exocyst and kinetic activation are important for exocytosis and the establishment and re-enforcement of cell polarity. The Lgl was originally identified as a tumor suppressor that plays a critical role in epithelial cell polarization. This study not only helps us understand the molecular basis of exocytosis, but also sheds light on the mechanisms of Lgl function in cell polarity.

424

**Involvement of syntaxin 18, an Endoplasmic Reticulum (ER)-localized SNARE Protein, in ER-mediated Phagocytosis**

K. Hatsuzawa,[1,2] H. Hashimoto,[1,2] Y. Yokoya,[1,2] H. Hashimoto,[1,2] T. Tamura,[1,2] I. Wada[1,2]; [1]Dept Cell Sci./Inst Biomed Sci, Fukushima Medical University, Fukushima, Japan, [2]CREST/JST, Kawaguchi-Saitama, Japan

The endoplasmic reticulum (ER) is thought to be a major source of membrane production during phagocytic invagination. Consistent with this, recent reports show that fusion of the ER to phagosomes is responsible for antigen cross-presentation mediated by MHC class I molecules. However, the exact mechanisms used to regulate the fusion remain elusive. In this study, we investigated the involvement of various SNARE proteins in membrane fusion between the ER and plasma membranes. When phagosomes were isolated from murine macrophages, J774 cells, we found a significant enrichment of ER-localized SNARE proteins (syntaxin 18 (syx18), D12, and Sec22b) in the fraction. Similarly, J774 cells stably expressing SNARE proteins tagged to GFP variants showed the accumulation of fluorescence on the phagosomal membranes. To determine whether those SNARE proteins are required for phagocytosis, we generated the 293T cells stably expressing Fcγ receptor, in which phagocytosis occurs in an IgG-mediated manner, and then we examined the effects of overexpression of the dominant-negative mutants lacking transmembrane domains. Interestingly, the inhibition was observed only in the cells overexpressing the soluble forms of syx18 and D12, but not that of Sec22b. Furthermore, when the expression of syx18 was inhibited by siRNAs, the phagocytosis efficiency was selectively decreased. Finally, we found that J774 cells overexpressing syx18 showed enhanced ingestion of luminol-beads. Therefore, we conclude that syx18 is required for ER-mediated phagocytosis, presumably through regulating specific and direct fusion of the ER and plasma membranes.

425

**Cell Cycle Regulation of Snare-mediated Membrane Fusion**

X. Ding,[1,2] K. Jiang,[1,3] C. Fu,[1] T. Ward,[1] H. Kim,[4] X. Yao[1,3]; [1]Physiology, Morehouse School of Medicine, Atlanta, GA, [2]Beijing Univ. of Medicine, Beijing, China, [3]Univ. of Sci. & Tech. of China, Hefei, China, [4]Pharmacology, Univ. of Alabama, Birmingham, AL

Cytokinesis is an essential process that segregates cellular contents into daughter cells. Aurora-B, a mitotic protein kinase, plays important roles in metaphase chromosome alignment, chromosome segregation, and cytokinesis. It has been shown that successful completion of cytokinesis requires a SNARE-mediated membrane fusion event at the midbody, a cytoplasmic bridge that connects the two prospective daughter cells. However, the molecular mechanisms underlying such cell cycle-dependent membrane fusion remain elusive. Here we show Aurora B interacts and phosphorylates syntaxin 2 in vitro and in vivo. In addition, Aurora B is co-distributed with syntaxin 2 in the midbody between daughter cells. Mass spectrometric analyses of syntaxin 2 phosphorylated in vivo and in vitro have identified a conserved phosphorylation site in syntaxin 2 subfamily. Preventing Aurora B-mediated phosphorylation of syntaxin 2 inhibits the assembly of SNARE complex and causes failure of cytokinesis leading to the formation of binucleated cells. Moreover, this phosphorylation of syntaxin 2 is reversed in vitro by Cdc14A. Thus, phosphoregulation of the syntaxin 2 by Aurora B ensures that SANRE complex assembly occurs at the appropriate time in the cell cycle and maintains genomic stability.

**Fusing Partner Cells Require Mutual Expression of the Autonomous Cellular Fusogen EFF-1**

J. J. del Campo, J. H. Shinn, M. R. Schiller, C. J. Staber, R. A. Reenan, W. A. Mohler; Dept. of Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT

Most cell fusion events in *Caenorhabditis elegans* require the phyletically distinct protein EFF-1 [1, 2, 3 ]. Inappropriate EFF-1 expression can also induce ectopic fusion fate in *C. elegans* tissues [2, 3]. We have tested the homotypic specificity and molecular autonomy of EFF-1 in driving cell fusion, and have begun to explore potential protein-interaction partners. First, we used genetic mosaic analysis in *C. elegans* to reveal a reciprocal requirement for EFF-1 expression in fusing cells. This result concurs with our observations of the dynamic localization of EFF-1::GFP in fusing embryonic cells [2]. Second, we tested the intrinsic sufficiency of EFF-1 by expression in a heterologous organism that does not possess an EFF-1 ortholog, showing that EFF-1 alone is sufficient to cause *Drosophila* neurons to undergo cell fusion. Therefore, EFF-1 appears to function independently, requiring simply that both partner cells express the protein in order to fuse. These properties make EFF-1 unique among known membrane fusogens, and may allow simple yet precise application of enforced cell fusion in experimental applications. Third, we have identified two potential 14-3-3-binding phosphopeptide motifs within the predicted cytoplasmic domain of EFF-1, and showed that they are required for cell fusion activity. These results inspire a model in which a combination of *cis* and *trans* interactions govern the highly specific targeting of EFF-1 to fusion-fated cell contacts in developing tissues. 1. **Proteomic Analysis of Cell-cell Fusion during Mating in S cerevisiae**

X. Bai, S. Liu, J. A. McNew; Biochemistry and Cell Biology, Rice University, Houston, TX

Cell-cell membrane fusion is an essential yet elusive process in eukaryotic organisms. Little is known about the mechanism of cell-cell membrane fusion. We are attempting to identify the fusogens mediating plasma membrane fusion during the mating reaction in *Saccharomyces cerevisiae.* Our strategy assumes that the potential fusogens are induced in response to mating pheromone and transported through the traditional secretory

pathway. Post-Golgi secretory vesicles were accumulated in a temperature sensitive *sec6-4*$^{ts}$ strain treated with synthetic alpha mating factor. The accumulated vesicles were purified by differential centrifugation and density sedimentation. Peak vesicle fractions were identified by immunoblot analysis with an antibody directed against the post-Golgi vesicle SNARE Snc1/2p. Peak vesicle fractions from cell treated with alpha factor and control untreated cells were analyzed by two-dimensional polyacrylamide gel electrophoresis. Visual inspection revealed approximately 80 protein spots with subtle differences between vesicles treated with or without alpha factor. We are currently obtaining sufficient quantities of purified vesicle to analyze by LC/MS/MS.

## Endocytosis I (428-448)

428

### Real-time Fluorescence Analysis of Receptor-mediated Endocytosis

J. Y. Toshima, J. Toshima, M. Kaksonen, A. C. Martin, D. S. King, D. G. Drubin; Department of California Berkeley, University of California Berkeley, Berkeley, CA

In both yeast and mammals, endocytic vesicle internalization is a dynamic process that requires coordinated interactions between plasma membrane proteins and the actin cytoskeleton. Much progress defining the order and timing of endocytic internalization events has come as a result of real-time, live-cell fluorescence microscopy. While the availability of numerous endocytic mutants makes yeast an especially promising organism for functional analysis of endocytic dynamics, a serious limitation has been the lack of a fluorescent cargo for receptor-mediated endocytosis, whose transit through the internalization pathway can be tracked visually. In this study, we succeeded in synthesizing fluorescently labeled mating pheromone derivatives, and discovered previously unknown spatio-temporal features of receptor-mediated endocytosis. These labeled pheromones maintained biological activity as assessed by induction of mating morphology in a cells, although the activities were about 25-50-fold less than for for wild-type alpha-factor. Using this novel endocytic marker, we found that actin patches were sites of receptor-mediated endocytic internalization. In addition, we found that endocytic proteins first assembled into patches on the plasma membrane, then alpha-factor associated with the patches, and finally internalization occurred concomitant with actin assembly at patches. Furthermore, endocytic vesicles moved on actin cables to facilitate efficient trafficking between the plasma membrane and endosomes, while endosomes could also actively move toward endocytic sites on actin cables to capture vesicles as they were being released from the plasma membrane. These studies establish that multiple steps during receptor-mediated endocytosis are mediated by filamentous actin, and that an endocytic ligand gets recruited to the endocytic machinery, and not vice versa.

429

### System-wide Live-cell Imaging of Actin-mediated Endocytosis

M. Kaksonen, C. P. Toret, D. G. Drubin; Department of Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA

Actin is emerging as a vital component of the endocytic machinery in organisms from fungi to mammals. Actin filaments are polymerized transiently at endocytic sites during vesicle budding, and this polymerization has been suggested to provide force for plasma membrane invagination and vesicle movement. We explored the mechanisms underlying this actin-mediated process by analyzing the dynamic behavior of GFP-fusion proteins marking either the endocytic coat or actin filaments in 60 mutant budding yeast strains each lacking one endocytic gene. This screen revealed phenotypes for 14 proteins. Dynamics of ten of these 14 proteins were examined by live-cell imaging. Quantitative live-cell analysis of both protein dynamics and corresponding deletion phenotypes suggested roles for these proteins at different steps during actin-mediated endocytic internalization. We found that clathrin, Sla1p and End3p play a role in initiating the assembly of the actin-based endocytic machinery, Bbc1p and capping protein (Cap1p and Cap2p) regulate the speed of the actin-driven coat movement, fimbrin (Sac6p) couples actin polymerization to coat movement, amphiphysins (Rvs161p and Rvs167p) play a role in vesicle scission and Abp1p in disassembly of the endocytic machinery. We also discovered that simultaneous deletion of both *BBC1* and *SLA1* genes caused formation of giant dynamic actin protrusions at endocytic sites. Remarkably, these protrusions were still able to drive endocytosis. Due to the large size of these actin structures (~10x normal) we were able to visualize membrane invagination and vesicle formation in relation to the actin protrusions in living cells. Furthermore, using local photobleaching of actin-GFP we showed that the actin protrusion that pushes the newly formed vesicle was polymerized at the plasma membrane, not at the vesicle surface. This mechanism is opposite to the classical actin-rocketing model for *Listeria* and endosome motility.

430

### Proteomic Analysis of Immunoisolated Apical Recycling Vesicles

L. A. Lapierre,[1,2] K. Avant,[1,2] J. S. Lowe,[3] A. L. Ham,[4] S. Hill,[4] J. R. Goldenring[1,2,3]; [1]Depart. of Surgery and Epithelial Biology Program, Vanderbilt Univ. Medical Center, Nashville, TN, [2]Nashville VA Medical Center, Nashville, TN, [3]Depart. of Cell and Developmental Biology, Vanderbilt Univ. Medical Center, Nashville, TN, [4]Depart. of Biochemistry and Mass Spectrometry Research Center, Vanderbilt Univ. Medical Center, Nashville, TN

The apical recycling system is responsible for the timely and accurate spatial trafficking of many receptor and transporters in polarized epithelial cells. To understand better the regulatory control of apical recycling in polarized cells we have used a proteomic approach to characterize immunoisolated tubulovesicular recycling membranes from the parietal cells of human stomach. Using a monoclonal antibody against the α-subunit of the gastric H/K-ATPase, we immunoisolated the vesicles out of an enriched tubulovesicle compartment from the resting human gastric mucosa of four organ donors. Proteins were eluted from the beads with 1% CHAPS and tryptic peptides were analyzed by LC-MS-MS. We identified and validated by western blots many of the components previously identified on recycling vesicles including the small GTPases Rab11 and Rab25 as well as Syntaxin 3, SCAMPs and VAMP2. We have now identified by proteomic analysis of immunoisolated vesicles Rabs 4 and 10 as well as VAMP8, syntaxins 7 and 12/13, pantophysin and the human homolog of YOP1p, DP1/TB2 as well as Annexins and S100-A10. Transfection of a stable GFP-Rab11a expressing MDCK cell line with Vamp8 or pantophysin caused a collapse of the GFP-Rab11a compartment, this effect was also observed, but less dramatic in syntaxin 7 and VAMP2 transfected cells. While overexpression of DsRed2-pantophysin altered the GFP-Rab11a compartment, it did not co-localize with the GFP-Rab11a but was localized to an adjacent tubular compartment. This proteomic examination of apical recycling vesicles from parietal cells has led to insights into membrane recycling regulators in epithelial cells.

431

**A Role of the Breakpoint Cluster Region Protein in Endocytosis**

E. K. Malmberg,[1,2] Y. Hou,[2] J. R. Riordan,[2] G. C. Hansson,[1] M. Gentzsch[2]; [1]Medical Biochemistry, Göteborg University, Gothenburg, Sweden, [2]Mayo Clinic College of Medicine, Scottsdale, AZ

The Breakpoint cluster region (Bcr) protein is multifunctional, participating in various signalling pathways. In addition to an N-terminal oligomerization domain it has four structural domains including a serine/threonine kinase, a tandem Dbl homology/Pleckstrin homology (DH/PH) domain characteristic of RhoGEFs, a GAP domain and a $Ca^{2+}$ -dependent phospholipid C2 domain in the C-terminus. Both GEF and GAP activities target some of the same Rho GTPase family members providing the possibility of bi-directional regulation of Rho controlled signalling pathways. These control many cellular functions involving the cytoskeleton and vesicular traffic. In addition to the previously known functional domains we found that Bcr also contains a clathrin binding box (CBB) as well as a consensus sequence for interaction with the AP-2 clathrin adapter complex. We show that Bcr binds both to clathrin and the α-adaptin subunit of AP-2. Although Bcr appears as an abundant cytoplasmic protein in most cells both the PH and C2 domains might be expected to mediate membrane association. This was confirmed with immunofluorescence microscopy on polarized human epithelial cells which showed a significant accumulation of Bcr at the plasma membrane. Isolation of clathrin coated vesicles from human cells of epithelial origin (HEK293) revealed that Bcr is enriched on these organelles. In BHK-21 cells stably overexpressing wild type Bcr, endocytosis was greatly exaggerated compared to wt BHK-21 cells, when measured by dextran Alexa-488 internalization analyzed by confocal microscopy. To conclude, we suggest that Bcr is acting as an endocytic adapter protein in clathrin mediated endocytosis.

432

**Regulation of "Constitutive" Endocytosis by Dynamin and Cortactin Phosphorylation**

H. Cao, J. Chen, A. E. Kruchten, M. A. McNiven; Center for Basic Research in Digestive Diseases and Department of Biochemistry and Molecular Biology, Mayo Clinic College of Medicine, Rochester, MN

The mechanisms by which epithelial cells regulate clathrin-mediated endocytosis (CME) are poorly defined. In fact, the endocytic internalization of many ligands such as transferrin is considered a constitutive process that occurs continuously without regulatory constraints. In this study, we demonstrate for the first time that endocytosis of the transferrin receptor is a regulated process that activates c-Src and, subsequently, multiple components of the endocytic machinery including the large GTPase dynamin (Dyn2) and its associated actin-binding protein cortactin. Immunoprecipitation of c-Src from cultured NIH/3T3 cells showed substantial levels of co-precipitated cortactin and Dyn2. In support of this, purified, recombinant Dyn2 and cortactin were phosphorylated by c-Src in vitro while Dyn2 and cortactin proteins with tyrosine residues mutated to phenylalanine (Dyn2:Y231F and Y597F and Cort:Y384F, Y429F, and Y445F) were not phosphorylated. When expressed in a cultured hepatocyte cell line (Clone 9), these mutant proteins significantly attenuated CME of transferrin. Consistent with these findings, expression of either a kinase dead (K297M) or a constitutively inactive (Y419F) form of c-Src also inhibited transferrin internalization. Finally, Clone 9 cells exposed to transferrin showed a significant increase in Dyn2 and cortactin phosphorylation compared to untreated cells, an increase exceeding that observed by cells treated with EGF. These findings are the first to implicate a c-Src-mediated endocytic cascade in what was previously presumed to be a non-regulated receptor-ligand internalization process.

433

**Functional Characterization of the Interaction between the Endocytic Sorting Adaptor Stonin 2 and Synaptotagmin**

N. Jung, M. K. Diril, V. Haucke; Institut fuer Chemie - Biochemie, Freie Universitaet, Berlin, Germany

Stonins 1 and 2 are the only mammalian orthologues of the *Drosophila melanogaster* stoned B protein, an endocytic protein implicated in synaptic vesicle recycling. Stonins interact with a variety of proteins involved in clathrin-mediated endocytosis (CME) including the adaptor AP2, Eps15, and intersectin. We have mapped the AP2 binding region to tandemly repeated WxxF motifs within the amino-terminal domain of stonin 2. Its carboxy-terminal μ-homology domain interacts with the C2B domain of several synaptotagmin family members. Pull down and co-immunoprecipitation experiments indicate a role for a basic cluster of amino acids within the C2B domain of synaptotagmin I in stonin 2 binding. Surprisingly we found that in addition to C2B also the C2A domain of synaptotagmin 1 is capable of interacting with stonin 2. The ability of stonin 2 to bind to AP2 and synaptotagmin both *in vitro* and *in vivo* suggests a function for stonin 2 in clathrin/AP2-mediated synaptotagmin internalization. In fact, we found that transfected synaptotagmin 1 located to the plasma membrane in fibroblasts is endocytosed in the presence of stonin 2. Current efforts are directed at dissecting the exact sorting mechanism involved in this pathway and at testing its relevance for vesicle cycling in the brain.

434

**The N and C Termini of Clathrin Light Chain Interact in a Calcium-calmodulin-dependent Manner: Implications for Neuronal Clathrin Trafficking**

S. L. Newmyer, V. Manalo, F. M. Brodsky; Hooper Foundation, University of California, San Francisco, San Francisco, CA

Clathrin-coated vesicle trafficking mediates diverse cellular functions, ranging from down-regulation of cell surface receptors to recycling synaptic vesicles. Different adaptor proteins have been demonstrated to promote various clathrin trafficking activities. However, clathrin is expressed in a tissue-dependent manner and, therefore, may also contribute to membrane trafficking diversity. Vertebrates express two light chains, LCa and brain-enriched LCb. Additionally, neuronal LCs contain 18-30 amino acid inserts through alternative splicing. In vitro, LCs negatively regulate coat assembly through an invariant LC N terminal EED motif. These residues may suppress heavy chain (HC) assembly by either binding HC directly or interacting with another LC region to modulate HC indirectly. Evidence exists that LC-LC interactions may occur. The present study aims to establish whether and how LC-LC interactions occur to understand how changing LC expression facilitates tissue-specific clathrin trafficking. Through co-precipitation assays utilizing GST-fused LCs and LC fragments, we find that LCs, indeed, bind one another. Our analysis identifies C terminal LCa residues 189-248, which includes a region of previously unknown function and the C terminal calmodulin binding domain, as the minimal fragment that binds the N-terminus. Addition of the neuronal insert, residues 158-188, within the GST-LC fragment enhances neuronal and non-neuronal LC co-precipitation. Thus, the neuronal insert may modulate LC-LC interactions. Calcium-calmodulin

inhibits LC-LC binding. Placing our findings in the context of biochemical HC assembly assays, we conclude that N-C terminal LC-LC interactions suppress coat assembly. Moreover the ability of calmodulin to disrupt LC-LC interactions suggests a potential calcium-regulated mechanism to allow rapid compensatory endocytosis at the firing synapse. Currently we are expressing LC fragments and mutants within hippocampal neurons to disrupt LC-LC binding and elucidate how this interaction modulates receptor-mediated versus compensatory endocytosis

435

**Interactions between the Yeast Endocytic Scaffold Pan1 and the Type I Myosins Myo3/5 Contribute to a Late Stage of Endocytosis**

S. L. Barker, B. Wendland; Department of Biology, The Johns Hopkins University, Baltimore, MD

The endocytic scaffold Pan1 of *Saccharomyces cerevisiae* is comprised of three regions; the amino-terminal adaptor-binding region, the central oligomerization region, and the carboxy-terminal F-actin-binding and Arp2/3 stimulation region. The carboxy-terminal region also contains an uncharacterized proline-rich domain (PRD) which contains ligand motifs predicted to bind to SH3 domains. We conducted a yeast two-hybrid screen to identify binding partners for the PRD and isolated clones corresponding to the SH3 domains of the type I myosins, Myo3 and Myo5. In vitro binding and in vivo co-immunoprecipitation assays validated this interaction. Two-color real-time fluorescence microscopy revealed the relative timing of recruitment of Pan1-GFP and Myo3/5-RFP to nascent endocytic sites; we found that Myo3/5 join Pan1 at cortical patches at a very late stage of internalization, just prior to the brief inward movement of Pan1 and its disassembly. Consistent with an in vivo role for the carboxy-terminal interactions of Pan1 and Myo3/5, we found that the widely used *pan1-20* temperature sensitive allele corresponds to a disruption of the PRD due to a frame-shift mutation in the open reading frame of the domain. *pan1-20* cells have an increased number of invaginations at the plasma membrane, consistent with a defect in vesicle scission. The pan1-20 protein has reduced affinity for Myo3/5, and *pan1-20* cells are deficient in recruiting Myo3/5 to endocytic sites. We propose that the interaction of Pan1 and the type I myosins promotes a late stage of endocytic internalization to facilitate endocytic vesicle scission.

436

**Recruitment of EH Domain-containing Endocytic Scaffold Proteins by Clathrin Adaptors is a Required Step in Endocytosis**

L. Maldonado-Baez, B. Wendland; Department of Biology, The Johns Hopkins University, Baltimore, MD

Endocytic adaptor proteins are involved in cargo selection and recruitment of other members of the machinery. Our previous work has demonstrated that the yeast epsins, Ent1 and Ent2, which are putative adaptors, are essential for viability in yeast. We have mapped the essential function of the epsins to the epsin N-terminal homology (ENTH) domain; the endocytic function resides in the C-terminus, which contains the characterized endocytic protein interaction motifs. The yeast Yap1801 and Yap1802 proteins, homologs of mammalian AP180/CALM, are structurally similar to the epsins. To test possible redundancy between these proteins as cargo adaptors in endocytosis, we created a quadruple delete mutant lacking the four adaptors and carrying a plasmid encoding the ENT1 ENTH domain (ENTH1) as the only source of epsin. We found that the ENTH1 domain complements quadruple delete cells, as we previously observed in ent1Δent2Δ cells. However, unlike ent1Δent2Δ+ENTH1, quadruple mutants+ENTH1 are inviable at 37°C and defective for endocytosis of the transmembrane receptor Ste3 at 30°C. Adding back either of the Yap180s restores growth at 37°C, suggesting that the Yap180s can replace a function of the epsin C-terminus. Ent1 truncations identified the minimal region of epsin required for endocytosis and 37°C growth in the absence of the Yap180; it must include the NPF tripeptide-containing motifs that bind to EH domain-containing endocytic scaffold proteins. Quadruple mutants+ENTH1 were rescued when co-transformed with an NPF-containing truncation of Yap1802, but not with a fragment lacking the NPF motifs. The evidence indicates an important role for interactions between adaptors and scaffolds for endocytosis and viability at 37°C. These results suggest that functional redundancy resides in adaptor C-termini, and that the NPF-motif/EH domain interaction is required for adaptors to recruit scaffolds to allow completion of endocytosis.

**BAR Domains of Human DIP13α/APPL and DIP13β Mediate Homotypic and Heterotypic Protein-Protein Interactions**

H. J. Chial, R. Wu, Y. Q. Chen; Cancer Biology, Wake Forest University School of Medicine, Winston-Salem, NC

Human DIP13α/APPL/APPL1 and DIP13β/APPL2 are members of a distinct family of proteins that contain a predicted N-terminal BAR (Bin/Amphiphysin/Rvs) domain, a central pleckstrin homology (PH) domain, and a C-terminal phosphotyrosine binding (PTB) domain. DIP13α exhibits PTB domain-mediated interaction with the intracellular domain of the deleted in colorectal cancer (DCC) protein and is required for DCC-mediated apoptosis (Liu et al., 2002). DIP13α also interacts with AKT protein kinases (Mitsuuchi et al., 1999), phosphatidylinositol 3-kinase (PI3K) subunits (Mitsuuchi et al., 1999), and the human follicle-stimulating hormone receptor (Nechamen et al., 2004). DIP13α and DIP13β are also RAB5 effectors that interact with GTP-bound RAB5 on a subset of endosomes (Miaczynska et al., 2004). Following epidermal growth factor (EGF) stimulation, DIP13α undergoes RAB5-dependent translocation from endosomal membranes to the nucleus (Miaczynska et al., 2004). Based on these findings, DIP13 proteins are predicted to function in a novel endosome-mediated signaling pathway linking the cell surface to the nucleus. Interaction between DIP13 proteins and RAB5 requires the DIP13 BAR domain and adjacent PH domain (Miaczynska et al., 2004). BAR domains are known for their ability to form crescent-shaped dimers capable of sensing and inducing membrane curvature. Using co-immunoprecipitation experiments, we have detected DIP13α-DIP13α, DIP13β-DIP13β, and DIP13α-DIP13β protein-protein interactions *in vivo*. We used the yeast two-hybrid system and deletion analyses to demonstrate that the DIP13α and DIP13β BAR domains are necessary and sufficient for mediating all homotypic and heterotypic DIP13-DIP13 protein-protein interactions. Taken together, our results show that DIP13α and DIP13β BAR domains function to promote homotypic and heterotypic DIP13-DIP13 interactions, and suggest that these interactions may play a role in DCC- and endosome-mediated signaling.

**The Signaling Adaptor Grb2 is Required for cMet Internalization**

N. Li,[1] K. Ireton,[2] L. A. Elferink[1]; [1]Dept. of Neuroscience and Cell Biology, University of Texas Medical Branch, Galveston, TX, [2]Biomolecular Science Center, Department of Molecular Biology and Microbiology, University of Central Florida, Orlando, FL

Increased cMet signaling underlies several human cancers, correlating closely with metastatic tendency, angiogenesis and poor prognosis. In normal cells, cMet activation is tightly regulated by signaling cascades and endocytosis. However, it remains unclear how cMet activation is

mechanistically linked to receptor endocytosis. Activation of the cMet receptor by ligand binding leads to recruitment of multiple signaling proteins, including the adaptors Grb2 and Gab1, to two 'docking site' tyrosines (Y1349 and Y1356), located in the C-terminal tail of the receptor. Since these tandem tyrosines are essential for the oncogenic activity of activated cMet, we examined their role in receptor endocytosis. In contrast to the situation with wild-type cMet, a mutant receptor in which both tyrosines 1349 and 1356 were changed to phenylalanine (Y1349,1356F) failed to undergo ligand-dependent internalization. In Y1349, 1356F expressing cells, cMet ubiquitination and phosphorylation of Gab1 and the E3 ubiquitin ligase Cbl were decreased, with negligible change in receptor tyrosine phosphorylation. Multiple lines of evidence suggest that the defect in Cbl phosphorylation and endocytosis of the mutant receptor were due to effects on Grb2, and not Gab1, recruitment. First, depletion of Grb2 by siRNA or inhibition of Grb2 recruitment through the use of dominant negative mutants impaired receptor ubiquitination and internalization. In contrast, genetic inactivation or siRNA-mediated knock-down of Gab1 did not block cMet endocytosis. Taken together, these results indicate that internalization of cMet requires Grb2, but not the Gab1 adaptor. Since Grb2 is constitutively associated with Cbl, it seems likely that the role of this adaptor in endocytosis is mediated in part, by Grb2-Cbl complexes. Future studies on the contributions of Grb2 and Cbl in the attenuation of cMet signaling through receptor internalization and degradation, will likely contribute to better understanding of mechanisms of oncogenesis.

**Post-translational Modification of the P Selectin Endocytic Motif Controls Receptor Degradation**

M. S. Roberts, D. Cutler; Laboratory for Molecular Cell Biology, University College London, London, United Kingdom

P selectin is a type 1 transmembrane protein found in the secretory granules of endothelial cells (Weibel Palade bodies). Following stimulation with proinflammtory mediators, P selectin is redistributed to the plasma membrane where it can interact with a counter-receptor (PSGL1) on leukocytes that leads to leukocyte rolling. Leukocytes stop rolling following chemo-attractant-mediated integrin activation, and then cross the endothelial barrier into the tissue where they carry out their inflammatory function. Unregulated long-term residence at the plasma membrane would lead to persistent leukocyte recruitment and chronic inflammation, but its rapid internalisation and subsequent endocytic trafficking is such as to preclude its uncontrolled return to the plasma membrane. We have identified an endocytic motif contained within the cytoplasmic tail of P selectin that is essential to traffic between early and late endosomes. This is a major sorting step determining the fate of P selectin, as P selectin may subsequently be degraded in the lysosome or recycled back to Weibel Palade bodies ready to act in a second round of inflammation. We have been studying the molecular mechanisms controlling this process and we determined that the post-translational modification of the endocytic motif of P selectin is essential to this sorting event.

**New Insights into Insulin-mediated Modulation of GLUT4 Endocytosis in Adipocytes**

V. Blot, T. McGraw; Biochemistry, Weill Medical College of Cornell, New York, NY

Insulin induces a large redistribution of the GLUT4 glucose transporter from intracellular storage compartments to the plasma membrane by increasing the rate of GLUT4 exocytosis and decreasing its rate of endocytosis. The effects of insulin on GLUT4 exocytosis are well described; the effects on endocytosis, however, are still controversial. Using quantitative fluorescence microscopy, we measured the internalization rates of HA-GLUT4-GFP reporter molecules in adipocytes in both basal and insulin-stimulated adipocytes. Insulin stimulation reduced GLUT4 internalization rate by 2 to 3-fold, whereas it increased the internalization of the transferrin receptor by about 1.5 fold. We analyzed the effect of mutations of the $F^{5}$QQI, $L^{489}$L and $E^{499}$LEY GLUT4 trafficking motifs on basal and insulin-modulated endocytosis. We discovered the following: 1) the $F^{5}$QQI motif is necessary for efficient GLUT4 internalization in the presence of insulin stimulation but dispensable in the basal state, 2) the $L^{489}$L motif is dispensable for internalization in both the basal and the insulin-stimulated states and 3) mutation of the $E^{499}$LEY motif did not affect internalization in basal adipocytes. This mutation, however, prevents the decrease in GLUT4 internalization upon insulin stimulation, indicating that insulin-inhibition of GLUT4 endocytosis requires the $E^{499}$LEY motif. Finally, only the combined mutation of both the $F^{5}$QQI and the $E^{499}$LEY was found to reduce GLUT4 internalization in basal adipocytes. This study starts to unravel, at a molecular level, the effect of insulin on GLUT4 internalization. Our results support a model in which insulin specifically modulates GLUT4 internalization rate by regulating the function of specific GLUT4 endocytosis motifs.

**Analysis of the Endocytic Behavior and Intracellular Localization of the C-type Lectin DC-SIGN**

H. Nassanian, B. Lee; Microbiology, Immunology & Molecular Genetics, UCLA, Los Angeles, CA

Dendritic cell-specific ICAM-3-grabbing non-integrin (DC-SIGN) is a C-type lectin receptor expressed by DCs implicated in the binding and transfer of human immunodeficiency virus (HIV). As a type II integral membrane protein, DC-SIGN has an extracellular C-terminal carbohydrate recognition domain, a hydrophobic transmembrane domain, and an N-terminal cytoplasmic domain (CD). The CD has three putative internalization/sorting motifs that may play a role in receptor endocytosis and trafficking, including a tyrosine-based motif (YKSL), a dileucine motif (LL), and an acidic cluster (EEE). By utilizing a cell surface biotinylation and endocytosis assay followed by an ELISA, the contribution of each motif in DC-SIGN endocytosis was examined in 293T transfectants. We have found that the dileucine motif accounts for most of the active endocytosis as both LL and YKSL/LL double mutants exhibited the same endocytic defect when compared to wild-type DC-SIGN. Endocytosis reached a plateau at 20 minutes, where 55% of wild-type DC-SIGN was endocytosed. Similar experiments were used to study the rate of DC-SIGN endocytosis in primary monocyte-derived dendritic cells (MDDCs). Indeed, endocytosis was more rapid, reaching a plateau in 10 minutes. Due to our ELISA-based format, the endocytic rate of DC-SIGN can be compared to other cell surface markers, like MHC class II and other DC lectins. The intracellular localization of DC-SIGN and its mutants was also studied by antibody uptake experiments analyzed by immunofluorescence staining. Microscopy data shows similar patterns with the dileucine and dileucine/tyrosine mutants being defective in internalization as compared to wild-type DC-SIGN. Co-localization of DC-SIGN and its mutants with organelle-specific markers will further explain the intracellular trafficking of this receptor. We will determine if the LL motif is active in MDDCs by competitive inhibition (via peptide transfection) with mutant peptides targeting these motifs in DC-SIGN.

**Sulfatide-facilitated Internalization of Cobra Cardiotoxin**

C. Wang, S. Lee, W. Wu; Department of Life Sciences, Hsinchu, Taiwan Republic of China

Amphiphilic β-sheet cobra cardiotoxins have recently been shown to target mitochondria and disrupt its network to regulate CTX-induced cell death pathway, but the mechanism involved in its internalization remains illusive. Herein, we show that the internalization of CTX A3, the major cobra cardiotoxin from Taiwan cobra, is a temperature-dependent, sulfatide-facilitated, and cholestyerol-inhibitory membrane de-limited process in H9C2 myoblast. In contrast to the internalization of other glycosphingolipid or glycosphingolipid binding toxins by a clathrin-independent, dynamin-dependent and cholesterol-sensitive caveolae/raft-dependent endycytosis, CTX A3 exploits a caveolin-, clathrin-, dynamin- and ATP-independent pathway. The process, however, can be promoted by heparan sulfate, with either cell surface bound or free form, when its carbohydrate chain length becomes longer than 10 residues. Based on the properties of CTX A3 action on model membranes and glycosaminoglycans, we suggest that heparan sulfate-promoted dimerization of CTX A3 with membrane favorable conformation may facilitate the binding of CTX A3 to sulfatide lipid phase and induce ATP-independent endocytosis. CTX A3 binding to sulfatide domain can be inhibited by enhancing cholesterol concentration. It also triggers a pathway shift of exogenous sulfatide internalization from a high cholesterol to a low cholesterol-mediated process for CTX A3 to be delivered to mitochondria and regulate CTX cytotoxicity.

443

**Clathrin Dependent Endocytic Trafficking of the ClC-3 Chloride Channel**

Z. Zhao, S. A. Weinman; Neuroscience and Cell Biology, Univ. of Texas Medical Branch at Galveston, Galveston, TX

ClC-3 is an intracellular chloride channel required for acidification of synaptic vesicles and endosomes. We have previously shown that a small portion of ClC-3 is transiently present on the plasma membrane and undergoes rapid endocytosis. The **OBJECTIVE** of this study was to determine whether plasma membrane ClC-3 represents a trafficking intermediate for intracellular localization the mechanism of its internalization. **METHODS:** A ClC-3 derivative was constructed by adding an HA epitope at position 1217 of an external loop. COS-7 cells were transfected with Fugene6 and observed under epi and confocal microscopy. N terminal and deletion fusion proteins were used in GST pull down assays. **RESULTS:** Incubation of live cells with anti-HA antibody specifically labeled plasma membrane localized ClC-3 where it colocalized with clathrin. After 15-30 min chase at 37°C, ClC-3 was primarily localized in small endocytic vesicles as evidenced by colocalization with clathrin and transferrin receptor. After 120min chase, ClC-3 was localized exclusively in large centrally located membrane structures that localized with lysosomal markers but not with clathrin. In GST pull down assays the N terminal of ClC-3 bound to clathrin heavy chain and AP-2 but not caveolin. Deletion of a segment within the cytosolic N terminal (amino acid 12-30) decreased endocytosis and increased steady state persistence at the plasma membrane. This deletion also abolished interaction with clathrin but not AP-2. **CONCLUSION:** ClC-3 targeting to endosomes and lysosomes occurs primarily via the indirect trafficking route where plasma membrane insertion and clathrin-dependent endocytosis are critical. An N terminal segment is responsible for clathrin binding.

**Differential Phosphorylation and Dephosphorylation Kinetics of β2-adrenergic Receptor Sites Ser 262 and Ser 355,356**

V. Iyer,[1] T. M. Tran,[2] E. Foster,[1] R. B. Clark,[2] B. J. Knoll[1]; [1]Pharmacological and Pharmaceutical Sciences, University of Houston, Houston, TX, [2]Integrative Biology and Pharmacology, University of Texas Medical School, Houston, TX

G protein-coupled $\beta_2$-adrenergic receptors ($\beta_2$ARs) are rapidly desensitized by phosphorylation of Ser262 by protein kinase A (PKA) and of Ser355,356 by G protein-coupled receptor kinase (GRK). We sought to determine whether the phosphorylation and subsequent dephosphorylation of these sites had similar kinetics and requirements for receptor endocytosis. The phosphorylation of the PKA and GRK sites were measured using antibodies that recognize pSer262 and pSer355,356. Endocytosis in stably transfected HEK293 cells was blocked by inducible expression of dominant negative dynamin-1 K44A or by treatment with hypertonic sucrose. The extent and kinetics of phosphorylation of the GRK site Ser355,356 during treatment with the strong agonist isoproterenol (ISO; 10μM) were unaffected by dynamin-1 K44A expression, and minimally by hypertonic sucrose. Under control conditions, the phosphorylation of the PKA site Ser262 during 10 μM ISO treatment peaked after 2 mins and then rapidly declined, but inhibition of endocytosis enhanced and prolonged this phosphorylation. Treatment with 300 pM ISO, where there is no receptor endocytosis or phosphorylation by GRK, also caused prolonged PKA site phosphorylation. The dephosphorylation of these sites was measured after removal of agonist and the addition of antagonist. Significant dephosphorylation of both phosphoserines was observed under conditions of very low endocytosis. The results indicate that the kinetics of $\beta_2$AR phosphorylation by GRK and PKA are distinct and differentially affected by endocytosis, and that receptor dephosphorylation can occur either at the plasma membrane or in internal compartments. Supported by grants 0455072Y from the American Heart Association, Texas Affiliate (BJK) and GM031208 from the NIH (RBC).

**Proteolytic Processing of the 315 kDa Human HARE/Stab2 Hyaluronan Receptor**

E. N. Harris, P. H. Weigel; Dept. of Biochemistry, University of Oklahoma HSC, Oklahoma City, OK

The human Hyaluronic Acid Receptor for Endocytosis (HARE; also called Stabilin-2) is the predominant endocytic clearance receptor for circulating hyaluronan (HA) and other glycosaminoglycans that originate from ECMs of tissues throughout the body. HARE is highly expressed in the sinusoidal endothelial cells of lymph node, spleen, and liver. The full-length human *hare* cDNA (7653 bp) encodes a glycoprotein of 2551 amino acids that migrates in SDS-PAGE to approximately 315 kDa. Immunopurification from human or rat spleen and liver revealed that HARE exists as two receptor isoforms (~315 kDa and ~190 kDa) that are likely the result of specific proteolytic cleavage of the full-length protein. The N-terminus of the 190 kDa spleen isoform corresponds to proteolytic cleavage before serine 1136 in full-length hHARE and does not contain consensus sequences for any known proteases. The same pattern of proteolytic processing is also observed in 293 cell lines, which stably express the full-length *hare* cDNA. Pulse-chase experiments using $^{35}$S-Cys/Met reveal that full-length 315 kDa HARE receptor is synthesized, glycosylated in the Golgi, and then presented on the cell surface before the appearance of the 190 kDa HARE. N-terminally labeled GFP-190 HARE is also cleaved to produce free GFP and the 190 HARE. Conversely, full-length HARE lacking the cytoplasmic and transmembrane domains (a secreted ectodomain) is not proteolytically cleaved, indicating that membrane anchorage is vital for receptor processing. We conclude that the proteolytic

cleavage of full-length HARE to create the second smaller isoform is a natural non-artifactual process and that both isoforms are actively engaged in glycosaminoglycan clearance. (Supported by NIH GM69961 and F32 GM070262-01A1).

**Glycosaminoglycan Binding and Endocytosis Mediated by Cells Expressing Recombinant Human HARE/Stab2 Receptor**

E. N. Harris, J. A. Weigel, S. Kiosseva, P. H. Weigel; Biochemistry & Molecular Biology, University of Oklahoma Health Sciences Center, Oklahoma City, OK

The Hyaluronic Acid (HA) Receptor for Endocytosis (HARE; also designated Stabilin-2) mediates systemic clearance of glycosaminoglycans from the circulatory and lymphatic systems. Two membrane-bound HARE iso-receptors (a full-length ~315 kDa form and a truncated ~190 kDa form derived by proteolysis) are highly expressed in sinusoidal endothelial cells of liver, lymph node, and spleen. Multiple clones of Flp-In 293 cell lines stably expressing full-length hHARE cDNA make both receptor isoforms (315 and 190) in culture, although the clones differ in total receptor expression levels and in their HA binding, endocytosis and degradation activities. Both receptor isoforms cross-react with three anti-rat HARE monoclonal antibodies, which recognize their extracellular domains and partially block specific endocytosis of HA by HARE. We also developed cell lines that secrete full-length HARE without the transmembrane and cytoplasmic domains. The secreted 315 kDa HARE ecto-domain was purified from media via metal-chelate chromatography. In an ELISA format, the ecto-domain binds to HA with a higher affinity than to chondroitin sulfates A-E. Unlabeled chondroitin sulfates A-E also blocked, to different degrees, HA endocytosis by 315 kDa HARE stable cell lines. To determine the cellular distribution of the two receptor isoforms, we are currently biotinylating intact or permeabilized cells and then examining the labeled 315 kDa and 190 kDa HARE proteins by Western analysis using streptavidin-HRP. Preliminary results suggest that more receptors reside within intracellular compartments than on the cell surface. We conclude that both the 315 kDa and 190 kDa HARE receptor isoforms can mediate glycosaminoglycan clearance via endocytosis and contribute to normal homeostasis. (Supported by NIH GM69961 and F32 GM070262).

**Enterocyte Toll Like Receptor-4 Mediates Phagocytosis and Translocation across the Intestinal Barrier**

C. L. Leaphart,[1] M. D. Neal,[1] J. Prince,[1] R. Levi,[1] J. Li,[1] T. Billiar,[1] S. Cetin,[1] S. Watkins,[2] D. J. Hackam[1]; [1]Surgery, Children's Hospital of Pittsburgh, Pittsburgh, PA, [2]Cell Biology, University of Pittsburgh, Pittsburgh, PA

Translocation of bacteria across the intestinal barrier is important in the pathogenesis of systemic sepsis, although the mechanisms by which bacterial translocation occurs remain largely unknown. We hypothesized that bacterial translocation across the intact barrier occurs after internalization of the bacteria by enterocytes in a process resembling phagocytosis, and that toll like receptor 4 (TLR4) is required for this process. We now show that FcRγIIa-transfected enterocytes can internalize IgG-opsonized erythrocytes into actin rich cups, confirming they have the molecular machinery required for phagocytosis. We further show that enterocytes can internalize *E. coli* into phagosomes, that the bacteria remain viable intracellularly, and that TLR4 is required for this process. TLR4 signaling was found to be necessary and sufficient for phagocytosis by epithelial cells as rat IEC-6 cells were able to internalize LPS-coated but not uncoated latex particles, and TLR4-transfected HEK-293 cells acquired the capacity to internalize *E. coli* whereas non-transfected HEK-293 did not. Strikingly, the internalization of gram negative bacteria into enterocytes in vivo and translocation of bacteria across the intestinal epithelium to mesenteric lymph nodes were significantly greater in wild-type mice as compared to mice with mutations in TLR4. These data suggest a novel mechanism by which bacterial translocation occurs, and suggest a critical role for TLR4 in the phagocytosis of bacteria by enterocytes in this process.

448

**Failure of Endocytosis in Experimentally Produced Amicronucleate Tetrahymena Cells**

R. Tsuchiya, J. Wolfe; Biology, Wesleyan University, Middletown, CT

It is now possible to experimentally induce the resorption of nuclei en masse in living cells. This was accomplished with *Tetrahymena*, a ciliated protozoan which has a large macronucleus controlling the metabolism of the cell and a small micronucleus that shows no signs of gene exppression. After pairing of mating types the micronucleus undergoes an extraordinary elongation. When 2.5 hr conjugants were exposed to colchicine elongation was reversed, and the micronuclei collapsed to a spherical shape. But then, collapsed micronuclei started to disappear. Astonishingly, after 5 hours of exposure to colchicine, about 50% of the paired cells lost their micronuclei. Elimination occurred by a lysosome-mediated mechanism suggestive of autophagy. Testing for growth of amicronucleates, we found that it was not possible, or was very rare. Suspecting that growth might be limited due to an inability to feed, we assayed for food vacuole formation, and found that cells identified as amicronucleate did not form food vacuoles. This observation raises the question of why micronuclear elimination results in a failure of phagocytosis. We are now exploring the possibility that micronuclear loss is accompanied by damage to the structure of the oral apparatus (OA) or its deep fiber. This would be consistent with observation by Haremaki et al (1996) who showed that amongst amicronucleates that were selected from cells that had divided under conditions of exposure to nocodazole, most showed some sort of damage to the OA. Relatedly, we are attempting to grow amicronucleate cells in an enriched growth medium known to support growth of mutant cells incapable of food vacuole formation. Finally, we should be able to harvest large numbers of amicronucleate cells with a magnetic separation of feeding cells that can phagocytose iron dextran particles, and probe why they do not grow.

## Protein Targeting (449-475)

449

**Mapping the Interaction of Mammalian SRP with Ribosome-Bound Nascent Chains**

A. L. Karamyshev,[1] I. Nilsson,[2] T. Hessa,[2] G. von Heijne,[2] A. E. Johnson[1]; [1]Medical Biochemistry & Genetics, Texas A&M University System Health Sciences Center, College Station, TX, [2]Department of Biochemistry and Biophysics, Stockholm University, Stockholm, Sweden

The signal recognition particle (SRP) recognizes signal sequences in nascent chains co-translationally and targets a ribosome•nascent chain complex (RNC) to the protein conducting channel (translocon) in the membrane of the endoplasmic reticulum (ER). Since the key structural elements of SRP recognition of signal sequence have not been defined at high resolution, we have examined the dependence of SRP binding to the

signal sequence as a function of its sequence. To assess the extent of SRP•signal sequence interaction, a photoreactive probe was incorporated into the middle of the preprolactin signal sequence by translating its mRNA (with an amber stop codon at the desired probe location) *in vitro* in the presence of $N^{\varepsilon}$-(5-azido-2 nitrobenzoyl)-Lys-$tRNA^{amb}$ (εANB-Lys-$tRNA^{amb}$) amber suppressor. A homogeneous population of RNC•SRPs containing a specific length of nascent chain was created by programming the translation with truncated mRNAs in the presence of purified canine SRP. Quantitative analysis of RNC•SRP photoadducts revealed that a decrease or increase in the charge at the N- or C-terminus of the signal sequence has only a mild effect on the association of SRP with nascent chains. However, alterations in the hydrophobic portion of the signal sequence severely affect SRP binding. Deletions of 1, 2, 3 or 4 hydrophobic leucines led to a gradual and finally complete inhibition of RNC•SRP complex formation. The photocrosslinking data correlate well with targeting efficiency and the extent of transport across the ER membrane. Thus, the hydrophobic core of the signal sequence is primarily responsible for its recognition and binding by SRP, while positive charges simply modulate the SRP•signal sequence affinity and its targeting to the translocon and translocation across the membrane.

**Folding of Nascent SecM within the Ribosome Exit Tunnel is Required for Translation Arrest**

C. A. Woolhead,[1] A. E. Johnson,[2] H. D. Bernstein[1]; [1]Genetics and Biochemistry Branch, National Institutes of Health, Bethesda, MD, [2]College of Medicine, Texas A&M University, College Station, TX

Recent work has shown that the *E. coli* "secretion monitor" protein (SecM) undergoes an elongation arrest which serves to regulate the synthesis of the downstream SecA protein. The arrest is signaled by an interaction between the C-terminus of nascent SecM and ribosomal proteins and rRNA that line the polypeptide exit tunnel. The arrest is relieved upon interaction of the SecM signal peptide with the translocase complex in the inner membrane. In this study we used fluorescent resonance energy transfer (FRET) to study the folding of nascent SecM inside the ribosomal tunnel. We found that the C-terminus of SecM has an elongated conformation, but adopts a more compact conformation as soon as the entire sequence that is required for elongation arrest has been synthesized. Mutations near the C-terminus of SecM, shown to abolish elongation arrest, did not inhibit the conformational change. In contrast, no conformational change was observed when wild-type SecM was synthesized on mutant ribosomes that fail to promote elongation arrest. In addition several interesting and novel mutations have been identified, in the C-terminus of SecM, which prevent compaction of the nascent chain but also preclude translation arrest. Taken together, these results suggest that folding of nascent SecM within the ribosome is not an intrinsic property of the polypeptide sequence but rather is induced by the ribosome at the point of translation arrest and that this compaction is necessary but not sufficient for elongation arrest to occur. We are currently investigating the interactions between the ribosomal proteins that line the tunnel walls and the nascent SecM polypeptide during the arrest process.

451

**Molecular Mechanism of a Small Molecule Inhibitor of Protein Translocation into the Endoplasmic Reticulum**

J. L. Garrison,[1] R. S. Hegde,[2] J. Taunton[1]; [1]Program in Chemistry and Chemical Biology and Department of Cellular and Molecular Pharmacology, University of California, San Francisco, CA, [2]Cell Biology and Metabolism Branch, National Institutes of Health, Bethesda, MD

Secretory and membrane proteins constitute roughly one-quarter of total cellular protein, and represent a majority of current drug targets. In mammalian cells, biogenesis of secretory and membrane proteins requires threading of the nascent polypeptide through a channel in the endoplasmic reticulum (ER) membrane, a process known as cotranslational translocation. Targeting proteins to the translocation channel is mediated by remarkably diverse $NH_2$-terminal signal sequences that share little or no sequence homology and whose functional significance is not known. We have recently described the first specific small molecule inhibitor of cotranslational translocation, *cotransin*, and identified its target as the Sec61 protein complex, which forms the core of the channel. Remarkably, the sensitivity of proteins to cotransin is determined by their signal sequence. Cotransin inhibits translocation in a substrate-specific and signal sequence-discriminatory manner by interfering with the stable insertion of the nascent chain into the Sec61 channel. To further understand the molecular basis for cotransin's selectivity, we are using labeled analogs to directly measure the binding interaction between cotransin and the Sec61 complex. The molecular details of the cotransin-Sec61 interaction are likely to shed light on the mechanism by which unrelated signal sequences gate a communal translocation channel.

452

**Human Sec16 Homologs Influence tER Organization**

D. Bhattacharyya, B. S. Glick; Molecular Genetics & Cell Biology, University of Chicago, Chicago, IL

*Saccharomyces cerevisiae SEC16* encodes a 240-kD peripheral membrane protein that is involved in COPII vesicle budding from the ER. COPII vesicle assembly occurs at ER subdomains called transitional ER (tER) sites, but the mechanism that generates tER sites is unknown. Using another budding yeast, *Pichia pastoris*, we have obtained evidence that Sec16 functions as a determinant of tER organization. A *P. pastoris* cell contains only 2-6 tER sites, whereas a typical vertebrate cell contains several hundred tER sites. If the tER organizing function of Sec16 is conserved, vertebrate cells should contain a Sec16 homolog. Using BLAST searches with a central conserved region of yeast Sec16, we found two putative homologs in mammalian cells. hSec16S, the smaller of these proteins, is a 1061-residue protein that lacks a conserved C-terminal domain found in Sec16 homologs from other species. The larger Sec16 homolog, hSec16L, codes for a 2154-residue protein and has the conserved C-terminal domain. hSec16S and hSec16L are distinct genes but share 49% identity. In HeLa cells, GFP fusions to both hSec16S and hSec16L colocalized precisely with the COPII component Sec23 in a typical tER pattern. We found that siRNA-mediated knockdown of hSec16S or hSec16L severely disrupted tER sites, as judged by immunofluorescence with an anti-Sec23 antibody. These results suggest that both hSec16S and hSec16L are required for tER organization in mammalian cells. We are characterizing the interactions of these two proteins with each other and with other tER components. This study will help to elucidate the mechanism of tER site biogenesis in mammalian cells.

453

**Role of Transmembrane Proteins p25 and p23 in Endoplasmic Reticulum Localization of Protein Tyrosine Phosphatase TC48**

V. Gupta, G. Swarup; Centre for Cellular and Molecular Biology, Hyderabad, India

T-cell protein tyrosine phosphatase (TCPTP) gives rise to two splice forms: TC48, which is the ER membrane resident form, and TC45, a nuclear protein. The present study was undertaken to identify proteins that are involved in targeting TC48 to ER. We identified two TC48- interacting

proteins, p25 and p23 from a yeast two hybrid screen. p23 and p25 are members of a family of putative cargo receptors that are important for vesicular trafficking between Golgi-complex and ER. Both p23 as well as p25 associated with TC48 in Cos-1 cells co-transfected with p23 or p25 and TC48 as determined by coimmunoprecipitation. A significant amount of TC48 colocalized with ERGIC and Golgi-complex markers in addition to ER and nuclear membrane localization. Analysis of TC48 localization in time-course experiment as well as the use of pharmacological reagents demonstrated cycling of TC48 between Golgi-complex and ER. Co-expression with p25 enhanced ER-localization of TC48 while coexpression with p23 resulted in its trapping in irregular vesicular structures. C-terminal 40 amino acids of TC48 (376-415) were sufficient for interaction with p23 (but not with p25) and targeted GFP to the Golgi complex. Targeting of GFP to ER required C-terminal 66 amino acids of TC48 (350-415) which showed interaction with p25 and p23. Thus the data presented here demonstrate that TC48 translocates to Golgi complex along the secretory pathway while its ER-localization is maintained by selective retrieval enabled by interactions with p25.

454

**GAD67 is Targeted to Golgi Membranes and Presynaptic Clusters Independent of GAD65**

J. M. Kanaani (Kanaaneh), J. Do, J. M. Diacovo, S. Baekkeskov; Dept. of Medicine, Microbiology/Immunology, and Diabetes Center, University of California San Francisco, San Francisco, CA

The functional divergence between the two isoforms of the GABA-synthesizing enzyme glutamic acid decarboxylase, GAD65 and GAD67, has been attributed to differences in their subcellular localization. While GAD65 is targeted to the membrane of synaptic vesicles that secrete its product GABA, GAD67 has been reported to be a soluble cytosolic molecule that can only acquire membrane association by heterodimerization with GAD65. In this study, we have used high-resolution confocal microscopy to further analyze the subcellular localization of endogenous rat GAD67 in primary hippocampal neurons and of transfected recombinant rat, mouse, or human GAD67 or GAD67-GFP in neurons and non-neuronal cells. The analyses revealed that endogenous GAD67 in rat neurons is localized primarily in presynaptic clusters and in the Golgi compartment with a localization that is indistinguishable from endogenous GAD65. To assess whether the membrane localization of GAD67 is dependent on GAD65, primary rat hippocampal neurons were singly transfected with either rat or mouse GAD67-GFP and then immunolabeled for endogenous GAD65. In these experiments, mouse GAD67-GFP showed the same Golgi localization and distribution in presynaptic nerve terminals in neurons that lacked endogenous GAD65. In contrast, rat GAD67-GFP showed a diffuse cytosolic localization and failed to associate with membranes in the absence of GAD65. These results are consistent with the confocal immunofluorescence analysis of MDCK and COS-7 cells, where the human GAD67 and mouse GAD67-GFP were localized in Golgi membranes, while the rat protein was cytosolic. Our results suggest that membrane anchoring and subcellular localization of mouse and human recombinant GAD67 is an intrinsic property of this isoform and not dependent on GAD65. We propose that published reports describing soluble GAD67 may be attributed to a defective rat GAD67 cDNA clone.

**Cell-Cycle Regulation of Organelle Biogenesis and Protein Trafficking in *Toxoplasma gondii***

M. Nishi,[1] K. Hu,[2] J. M. Murray,[3] D. S. Roos[1]; [1]Biology, University of Pennsylvania, Philadelphia, PA, [2]Cell Biology, The Scripps Research Institute, La Jolla, CA, [3]Cell and Developmental Biology, University of Pennsylvania, Philadelphia, PA

Apicomplexan parasites employ an unusual mechanism for replication, assembling daughters within the mother. Because rapid multiplication correlates with pathogenesis, it is important to understand the coordination of parasite assembly. With only a single copy of many subcellular organelles (unlike most eukaryotes), organellar segregation is critical to this process. Time-lapse microscopy shows that Golgi division and apicoplast (a secondary endosymbiotic plastid) elongation are among the first morphologically observable events, preceding formation of the daughter cytoskeletal scaffold. These events are associated with centriole migration from the apical to basal end of the nucleus, followed by centriolar replication, and migration back to the apical end. Cytoskeleton growth proceeds from the apical end, first encapsulating the ER/Golgi, from which the secretory organelles (micronemes and rhoptries) are produced *de novo*. Further growth of the cytoskeletal scaffold results in partitioning of the apicoplast, nucleus, and ultimately the mitochondrion, which enters the developing daughters rapidly, very late during mitosis. Defining an accurate timetable for organellokinesis permits detailed analysis of nuclear-encoded protein trafficking to apicoplast and secretory organelles. Fluorescence recovery after photobleaching (FRAP) shows that proteins target to the apicoplast via vesicles directly from ER only when the organelle is elongating prior to daughter cell formation (most efficiently during Golgi fission), but not during subsequent stages of cell division or interphase. Treatment with Brefeldin A (BFA) causes apicoplast lumenal or membrane proteins to accumulate in the ER or the tubulo-vesicular Golgi respectively only during the period of apicoplast protein trafficking. In contrast, FRAP shows that protein trafficking to micronemes transiting ER and Golgi occurs during the interphase and late cell division stage, but not during the period of efficient apicoplast protein trafficking. Treatment with BFA causes the cell-cycle dependent accumulation of microneme proteins in ER.

**The Role of Ent3p and Ent5p in Intracellular Trafficking in Yeast**

A. Copic, R. Schekman; Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA

The phosphoinositide-binding proteins Ent3p and Ent5p are required for transport of proteins from the *trans*-Golgi network (TGN) to the vacuole in *Saccharomyces cerevisiae,* but their precise role in protein sorting is not understood. Both proteins interact with the monomeric clathrin adaptor Gga2p, which is involved in trafficking to the vacuole, but Ent5p also interacts with the clathrin adaptor protein complex 1 (AP-1) *in vivo* (1). AP-1 facilitates trafficking of proteins, such as the chitin synthase Chs3p, between the early endosome and the TGN. We examined the effect of *ent3* and *ent5* mutations on the trafficking of Chs3p. Chs3p functions at the cell surface, but it is also maintained in an intracellular pool by cycling between the TGN and the early endosome in AP-1 vesicles. Chs6p is required for normal transport of Chs3p to the cell surface, but in *chs6Δ* cells, transport of Chs3p to the plasma membrane is restored by mutations in the AP-1 subunits (2). Similarly, we find that Chs3p is present at the cell surface of *ent3Δ ent5Δ chs6Δ* cells, but it is only intracellular in *ent3Δ chs6Δ* or *ent5Δ chs6Δ* cells. We isolated endogenous Ent3p and Ent5p from yeast by tandem-affinity purification, and Chs3p was found to copurify with both proteins, suggesting that Ent3p and Ent5p may directly interact with Chs3p. This interaction did not depend on the presence of the AP-1 complex. (1) Duncan, M., *et al.* (2003) *Nature Cell Biol* 5, 77. (2) Valdivia, R. H., *et al.* (2002) *Dev Cell* 2, 283.

**The Signal and Intracellular Location of AP-1-Dependent Sorting of Chitin Synthase III in Yeast**

T. Starr, R. Schekman; University of California, Berkeley, Berkeley, CA

In *Saccharomyce cerevisiae* the integral membrane protein chitin synthase III (Chs3p) exhibits a steady state localization at the *trans*-Golgi network and early endosomes, as well as at the bud neck region of the plasma membrane. Traffic of Chs3p to the bud neck is mediated by the peripheral membrane proteins Chs5p and Chs6p. Deletion of either Chs5p or Chs6p inhibits Chs3p trafficking to the bud neck, and thus restricts Chs3p to the *trans*- Golgi network and early endosomes. Cyclic trafficking of Chs3p between these intracellular compartments is dependent on the adaptor protein complex 1 (AP-1) (1). In a *chs6Δ* background deletion of any of the four subunits of AP-1 inhibits the trafficking of Chs3p between the *trans*-Golgi network and early endosomes, and restores Chs3p trafficking to the plasma membrane. We have identified a sorting signal in Chs3p that is required for its intracellular trafficking. The signal conforms to the types of signals to which AP-1 is known to bind, and mutation of the signal permits the trafficking of Chs3p to the plasma membrane in a *chs6Δ* background, thus mimicking the effects of AP-1 mutations. Additionally we have found that Chs3p and AP-1 physically interact and that mutations in the sorting signal impair this interaction. Therefore, we propose that we have identified an AP-1-dependent sorting signal in Chs3p. To determine the compartment at which Chs3p and AP-1 interact we are currently using microscopy to assay for the localization of fluorescently tagged Chs3p and AP-1 proteins. 1. Valdivia et al. (2002) Dev Cell 2, 283-294.

**Physiological Basis for Amino Acid Dependent Regulation of the *GAP1* permease**

A. L. Risinger, C. A. Kaiser; Biology, MIT, Cambridge, MA

The general amino acid permease, *GAP1*, of *S. cerevisiae* is responsible for the high capacity transport of all naturally occurring amino acids for use as a nitrogen source. Amino acid import through *GAP1* is tightly regulated by the quantity of amino acids available in the medium as well as the quality of the nitrogen source. We have determined that *GAP1* activity is repressed in response to elevated amino acid levels through transcriptional repression, ubiquitin-mediated sorting of the permease to the vacuole, and reversible inactivation of the permease at the plasma membrane. The identification of mutants that override different phases of *GAP1* regulation has allowed us to determine a physiological basis for the stringent control of *GAP1* activity. We have found that the dual transcriptional control of *GAP1* as a function of both nitrogen source quality and amino acid quantity limits expression of the permease when it would not be sorted to the plasma membrane while allowing internal pools of *GAP1* to accumulate in preparation for worsening nutritional conditions. We also find that mutants defective in the ubiquitin-mediated sorting of *GAP1* to the vacuole are sensitive to the addition of amino acids as a consequence of a toxic internal amino acid imbalance. Together, these data demonstrate that *GAP1* activity is tightly regulated in at least three distinct ways to allow for rapid changes in amino acid import to optimize growth in under a wide range of extracellular amino acid concentrations.

**Silencing of m1b in MDCK Cells Affects Recycling but Not Biosynthetic Delivery of TfR**

D. Gravotta,[1] A. Deora,[1] R. Schreiner,[1] A. Soza,[2] C. Oyanedel,[2] A. González,[2] E. Rodriguez-Boulan[1]; [1]Dyson Vision Research Institute, Weill Medical College of Cornell University, New York, NY, [2]Depto. Immunol. Clin. and Reumatol., Fac. Medicina and Centro de Regulación Celular y Patología, Fac. Ciencias Biológicas. Pontificia Universidad Católica de Chile, and MIFAB, Santiago, Chile

To date, all studies on the sorting role of the epithelial adaptor AP1B have been carried out in LLC-PK1 cells, a pig epithelial cell line, which naturally lacks m1B subunit and sorts LDLR and TfR to the apical plasma membrane. Here, we have silenced the expression of dog m1B by transfection of 21mer- double stranded RNA oligonucleotides or pSuper vector carrying silencing sequences. MDCK cells transiently and permanently silenced for m1B (m1B-KD MDCK) distributed LDLR and TfR to the apical membrane. We then used a novel biochemical approach involving pulse chase and the addition of apical or basolateral biotinylated Tf to study the biosynthetic and recycling routes of Tf-R in polarized m1B-KD MDCK cells. Biosynthetic delivery of Tf-R occurred as in control cells, preferentially towards the basolateral membrane. In contrast, recycling of TfR occurred preferentially towards the apical membrane. We conclude that, as previously shown in LLC-PK1 cells (Gan, McGraw and Rodriguez-Boulan, Nature Cell Biology, 2002), the sorting function of AP1B appears to be in a post-endocytic compartment; this recycling compartment does not appear to be located in the biosynthetic route of TfR. Supported by grants from NIH to ERB and by FONDAP and Millenium grants to AG.

**Two Step Targeting of AAM-B to Lipid Droplets (Adiposomes)**

J. K. Zehmer, R. Bartz, P. Liu, R. G. W. Anderson; Cell Biology, University of Texas Southwestern Medical Center, Dallas, TX

Recently our knowledge of lipid droplet (adiposome) proteins has expanded dramatically due to several proteomic analyses in several cell types. However, our understanding of how these proteins are targeted to adiposomes is still very limited. Analyses of adipophilin and perilipin found that these proteins have multiple, redundant regions containing targeting information, but a specific targeting signal has not been identified. We previously found the protein AAM-B (also known as DKFZp586A0522) in a proteomic analysis of CHO K2 adiposomes. In the current study we have examined in detail the targeting of this putative methyltransferase to HeLa cell adiposomes by transient transfection and immunofluorescence of immuno-tagged constructs. We found that AAM-B is directed to adiposomes by two distinct signals. First, an N-terminal hydrophobic alpha helix directs AAM-B to the endoplasmic reticulum. There, a second signal, contained in a 45 amino acid region just C-terminal to the hydrophobic helix, directs AAM-B to the adiposome. An alanine scan of this region identified two 3 amino acid patches that are critical for targeting. The hydrophobic helix and the downstream region, contained in amino acids 1-73, are sufficient to target GFP to adiposomes. Finally, we demonstrate that AAM-B forms homo-dimers or possibly higher-order oligomers, but that oligomerization is not required for adiposome localization.

**Ykt6 and Sedlin Colocalize in a Novel Cytoplasmic Protein-Lipid Particle**

Y. Liang,[1] H. Hasegawa,[2] V. Oorschot,[3] J. Klumperman,[3] J. C. Hay[1]; [1]Division of Biological Sciences, University of Montana, Missoula, MT,

[2]National Institutes of Health, Bethesda, MD, [3]Department of Cell Biology, University Medical Center Utrecht, Utrecht, The Netherlands
The function and targeting of the mammalian SNARE ykt6 has been controversial. While others have reported a Golgi localization and transport function in kidney cell lines, we reported that ykt6 is expressed primarily in neurons, where its longin domain targets the protein to unidentified particulate structures assumed to represent novel membrane organelles. Here we used immunoelectron microscopy to examine the novel structures in PC12 cells. They appeared as ~200 nm electron-dense particles lacking a limiting membrane and exhibiting ykt6 labeling throughout. These particles precede cell fixation and represent the "natural" state of ykt6. To reconcile differing views of ykt6, we quantified its participation in traditional membrane SNARE complexes versus non-traditional organelles. Up to 20% of particulate ykt6 in PC12 cells can participate in SNARE complexes, while ~80% appears to be unavailable and resides within a protease-resistant structure presumably corresponding to the electron-dense particles. The protease-resistant structures lack a chaotropic agent-protective membrane but their buoyant density indicated that they contained significant lipid. Although ykt6 can be doubly lipidated, the particles did not appear to represent ykt6 "micelles" whose association is driven by lipid interactions. Rather, the particles appear to originate by self-association of longin domains, with the lipid, not necessarily covalently attached to ykt6, sequestered in the lipid-binding surfaces of the longin domain. Finally, we found that ykt6 was not the only longin protein present in the particles. Sedlin, mutations in which cause the skeletal disease *spondiloepiphyseal dysplasia tarda*, co-localized with ykt6 to the structures. In summary, ykt6 and sedlin exist naturally in ~200 nm, protease-resistant, protein-lipid particles not related to traditional SNARE function that have the potential to act as cytoplasmic "lipid rafts". We speculate that these longin structures may be important for neuronal lipid storage, transport, or metabolism.

**Stimulation of G-protein Coupled Receptors Induces Nuclear Localization and Membrane Translocation by Palmitoylation of Histamine N-Methyltransferase**

M. Ogasawara,[1] K. Yamauchi,[2] Y. Satoh,[3] K. Maeyama[1]; [1]Depart. of Integrated life science Div. of Pharmacology, Ehime University School of Medicine, Toon city, Japan, [2]Third Depart. of Medicine, Iwate Medical University, Morioka city, Japan, [3]Depart. of Anatomy, Iwate Medical University, Morioka city, Japan
Objects: Histamine *N*-methyltransferase (HMT) is a principal enzyme to inactivate histamine, localizes in airway epithelium and plays a critical role in regulating allergic reaction of histamine. We reported the translocation of HMT molecules to plasma membrane with plasma membrane protein biotinylation method. However, the molecular mechanism of translocation remains elucidated. Using endogenously expressed histamine receptor and β adrenergic receptor in HEK293 cells, we investigated the molecular basis of translocation of HMT. Methods: HEK293 cells stably transformed with C-terminal HA tagged HMT cDNA were cultured for 4 hours with [$^3$H] palmitic acid in the presence or absence of isoproterenol or/and histamine. Cell extracts were immunoprecipitated with antibodies against HA tag. Incorporation of [$^3$H] palmitic acid were measured. Moreover, the HEK293 cells were stimulated in the presence or absence of beta adrenergic receptor agonist, isoproterenol (10υM) and/or histamine followed by staining with antibodies against HA tag and immunofluorescein. Results: HMT molecules were palmitoylated and inhibited by palmitoylation inhibitor, 2-bromopalmitic acid. Beta adrenergic receptor stimulation enhanced the palmitoylation of HMT. Moreover the stimulation of beta adrenergic receptor and /or histamine receptor induced the nuclear translocation of HMT. Conclusion: HMT molecules were modified with palmitoylation, which was enhanced with stimulation of beta adrenergic receptor, suggesting that molecular basis of plasma membrane localization of HMT can be partly explained by lipid modification. Translocation of HMT from cytoplasm to nucleus after stimulation with beta adrenergic receptor and/or histamine receptor suggest that HMT may have other function than histamine inactivation or another function of histamine in the nucleus could be suggested because of histamine transportation into cell through organic cation transporters. Moreover we may need to reevaluate the substrate specificity of HMT for amine derived compounds.

**The Phogrin Luminal Domain Dense Core Granule Sorting Signal Can Act at the Plasma Membrane**

J. Wenzlau,[1] P. Burgos,[1] R. Bauer,[1] C. Wasmeier,[2] H. Davidson,[1] J. Hutton[1]; [1]Barbara Davis Center, UCDHSC, Aurora, CO, [2]Imperial College, London, United Kingdom
Phogrin is an integral membrane protein of neuroendocrine dense-core secretory granules (SGs). Newly synthesized phogrin apparently traffics to SGs without prior exposure at the plasma membrane (PM). Previously we have shown that key targeting information resides in both the luminal and cytoplasmic domains. Mutants lacking the cytosolic domain (ΔC), and a chimera comprising the luminal and transmembrane domains of Tac fused to the phogrin cytoplasmic domain, are both efficiently sorted to SGs in transfected AtT20 cells. However, it is uncertain if either mutant follows an identical intracellular itinerary to the native molecule. To address this question we have studied in more detail the trafficking and post-translational processing of wild-type and mutant phogrin. Pulse-chase experiments show that both wild-type phogrin (WT; 130kDa) and ΔC (100kDa) are proteolytically processed to their mature forms in an acidic post-TGN compartment within 2h of labelling. Processed ΔC co-distributes with both processed mature WT and insulin on sucrose density gradients, suggesting that proteolysis occurs in immature and/or mature SGs. In contrast to WT, a significant fraction of radiolabelled ΔC-precursors can be surface biotinylated, indicative of their mis-sorting to the PM. However, biotinylated ΔC-precursors are also efficiently processed, suggesting that this mutant can follow an indirect route to SGs. Antibody uptake experiments demonstrate that mature WT is internalized after stimulated secretion, and within 30 min accumulates in perinuclear structures that co-localize with internalized transferrin. Phogrin ΔC precursors similarly congregate in transferrin positive perinuclear compartments implicating recycling endosomes in post-endocytic transit to SGs. We conclude that signals in the luminal domain of phogrin can act at the PM and/or transferrin positive endosomes, rather than exclusively at the TGN as we had previously proposed.

**The Transmembrane Domain of the PC3: A Key Motif for Targeting to the Regulated Secretory Pathway**

H. Lou,[1] A. M. Smith,[2] L. C. Coates,[2] N. P. Birch,[2] Y. P. Loh[1]; [1]Section on Cellular Neurobiology, NICHD/National Institutes of Health, Bethesda, MD, [2]Laboratory of Molecular Neuroendocrinology, University of Auckland, Auckland, New Zealand
The biosynthesis of hormones and neurotransmitters involves post-translational cleavage of proprotein precursors at basic amino acid cleavage sites by a family of prohormone convertases. Processing of precursors in regulated secretory pathway occurs primarily in secretory granules that bud

from the *trans* Golgi Network. This study reports a role for the transmembrane domain (aa 617-638) of the prohormone convertase 3 (PC3) in sorting to regulated secretory granules. Membrane extraction and sucrose density gradient analyses showed differential association of full length (PC3-FL) and carboxyl terminus-truncated forms of PC3 with (PC3-638) or without (PC3-616) the transmembrane domain in Neuro2A cell membranes. Similar to PC3-FL, PC3-638 was associated with lipid rafts in membranes but not PC3-616. PC3-638 showed robust stimulated secretion. Immunocytochemical analysis demonstrated a high level of co-localization of PC3-638 with a secretory granule marker, chromogranin A, in cell processes. In contrast, PC3-616 underwent constitutive secretion and was localized mainly in the perinuclear region of the cell body. These results indicate that within the framework of the PC3 molecule, the transmembrane domain ($PC3_{619-638}$) plays a key role in sorting the enzyme to the regulated secretory pathway. We therefore propose that interaction of the transmembrane sorting domain of PC3 with lipid rafts at the *trans* Golgi Network is the mechanism by which PC3 is sorted into the budding granules of the regulated secretory pathway.

**Determining the Subcellular Localization of Type II Membrane Proteins**

R. N. Aturaliya,[1] L. Fink,[1] M. J. Davis,[1] M. S. Teasdale,[1] K. A. Hanson,[1] K. C. Miranda,[1] H. Suzuki,[2] R. D. Teasdale[1]; [1]Institute of Molecular Biology, Brisbane, Australia, [2]RIKEN Genomic Sciences Centre, Yokohama, Japan

Subcellular localization plays a pivotal role in determining protein function. The subcellular localization of membrane proteins is dependant on features such as signal peptides and transmembrane domains which determine membrane organization. A computational membrane organization prediction pipeline, MemO, classifies putative type II membrane proteins as proteins predicted to encode a single alpha-helical transmembrane domain and which lack a predicted signal peptide. MemO was applied to RIKEN's Isoform Protein Set which identified 2,869 transcripts encoding putative type II membrane proteins clustered into 2,149 non-overlapping genomic regions, or Transcriptional Units (TUs). This study focuses on TUs containing exclusively type II transcripts. Transcripts with overlapping InterPro and transmembrane domains were reviewed to remove proteins with inaccurate transmembrane domain predictions. Using this dataset, we developed a systematic protocol to document the subcellular localization of type II membrane proteins. This approach combines mining of published literature to identify subcellular localization data as well as a high-throughput, PCR-based experimental approach to characterize subcellular localization. These approaches have provided localization data for 221 and 169 proteins, respectively. Type II membrane proteins localize to all major organelle compartments, however, some biases were observed including a high prevalence in the early secretory pathway and punctate structures. Collectively, this study reports the subcellular localization of 24% of the final type II dataset comprised of 1,407 TUs. Localization data for all classes of membrane proteins is presented in a web-accessible database, LOCATE (http://locate.imb.uq.edu.au). Currently, the database reports membrane organization predictions as well as literature-mined and experimentally determined high-throughput subcellular localization data. The database contains literature localization data for over 1400 TUs, of which over 1000 represent membrane proteins, and experimental localization data for over 400 membrane proteins.

466

**Differential Targeting of R9AP and Syntaxin 3 in Transgenic *Xenopus* Photoreceptors**

S. A. Baker,[1] M. Haeri,[2] B. E. Knox,[2] V. Y. Arshavsky[1]; [1]Ophthalmology, Duke University Medical Center, Durham, NC, [2]Biochemistry and Molecular Biology, SUNY Upstate Medical University, Syracuse, NY

Photoreceptors are compartmentalized, polarized sensory neurons. At the distal end of the cell is the outer segment, a ciliary organelle specialized in phototransduction. At the proximal end of the cell is the synaptic terminal which communicates with the secondary neurons of the retina. The mechanisms that specifically target proteins to these different compartments are largely unknown. R9AP (RGS9 Anchor Protein) is located in the outer segment and is a member of the extended SNARE protein family. It is required for the delivery of the GTPase activating protein, RGS9 (Regulator of G protein Signaling, family member 9), to the outer segment and for the regulation of its activity. The structural organization of R9AP is identical to that of syntaxin 3 which is the major syntaxin protein in photoreceptor synaptic terminals. Both contain two cytoplasmic domains, a three helical bundle and the SNARE homology domain, followed by a transmembrane domain at the C-terminus. The goal of this study was to identify the domains responsible for the differential targeting of these proteins. Our approach was to transgenically express EGFP-tagged mutants of these proteins in *Xenopus* rod photoreceptors. We have found that C-terminally tagged full-length R9AP and syntaxin 3 are correctly targeted to their respective subcellular locations. Minimal constructs containing just the transmembrane domain of either protein was found to accumulate in the outer segment. We conclude that in photoreceptors the targeting motif is located in the cytoplasmic parts of these proteins. This is in contrast to the finding in polarized epithelial cells where the transmembrane domains of syntaxins 3 and 4 do mediate their apical versus basolateral membrane targeting (Bulbarelli et.al, 2002). We are now using chimeric R9AP/syntaxin 3 proteins to identify the specific location of the targeting motif used in photoreceptors.

**Development of a Novel, Raman-Active Labeling System for Real-Time Monitoring of Cellular Processes**

W. E. Doering, M. Sha, M. Yamanaka, G. Freeman, S. Penn, M. J. Natan; Biotechnology, Nanoplex Technologies, Inc., Mountain View, CA

Imaging of biochemical functionality within live cells can occur only with the use of an appropriate biological stain or dye to generate the contrast needed for image generation. The ability to image simultaneously multiple different functions therefore requires multiple distinct detection tags. Techniques have been traditionally limited to the simultaneous detection of just a few species, due to the limited excitation and emission profiles of organic fluorophores. Recently, quantum dots have shown the potential to expand the multiplexing capability of optical techniques to perhaps five colors. We have recently developed a completely novel optical tag based on surface-enhanced Raman scattering (SERS). The tags are composed of a gold core that is coated with a Raman "reporter" molecule and encapsulated with a silica shell. Upon excitation, the profiles of the tags are determined exclusively by the Raman reporter. SERS nanotags have many optical properties that make them ideal candidates for cellular imaging; they can be easily excited in the near-IR (785 nm for example), they do not photobleach (allowing for extended viewing experiments), and distinct optical signatures are easily generated without changing the properties of the nanoparticles, such as size or surface chemistry. We have selectively conjugated two distinct "flavors" of SERS nanotags to separate antibodies and labeled SKBR-3 breast cancer cells based on the expression of the her2-neu receptor and a nuclear envelope protein. We have also developed efficient optical tags producing 4 distinct spectral responses upon NIR excitation, which is highly favorable to the UV-excitation required to monitor multiple quantum dot flavors. It is straightforward to envision

expansion to 10-20 different flavors of SERS-active tags, which would allow unprecedented real-time tracking of multiple proteins and pathways in cells under NIR excitation.

**Enzyme Recruitment and the Distributions of 3' Phosphoinositides during Fc Receptor-Mediated Phagocytosis**

L. A. Kamen, J. A. Swanson; Microbiology and Immunology, University of Michigan Medical School, Ann Arbor, MI

Enzyme Recruitment and the Distributions of 3'Phosphoinositides during Fc Receptor-Mediated Phagocytosis Changing concentrations of 3' phosphoinositides at the plasma membrane define signaling transitions that allow Fc receptor-mediated phagocytosis in macrophages. Phosphatidylinositol 3 kinase (PI3K) and the lipid phosphatases PTEN and SHIP-1 are capable of modifying levels of 3'phosphoinositides and are important in this process. It was previously shown that both SHIP-1 and p85, the regulatory subunit of type I PI3K, localize to the phagosome. Moreover, 3' phosphoinositides have been localized to the phagosomes, but their dynamics relative to enzyme localization are not well defined. We used ratiometric fluorescence microscopy of YFP chimeras expressed in macrophages to examine the dynamics of phosphoinositides and the enzymes that control their concentrations during FcR-mediated phagocytosis. The distribution of $PI(4,5)P_2$ and $PI(3,4,5)P_3$ were inferred using YFP chimeras of pleckstrin homology (PH) domains from Plcδ1 and Btk, respectively. $PI(4,5)P_2$ was present initially on the plasma membrane but diminished throughout the course of phagocytosis. In contrast, $PI(3,4,5)P_3$ was absent from resting plasma membrane, increased on the phagosome and remained elevated until after closure. YFP-p85 was present on the phagosome throughout phagocytosis and remained after closure in punctate structures. YFP-PTEN and YFP-SHIP-1 showed different distributions during phagocytosis; YFP-PTEN never localized to the phagosome but YFP-SHIP-1 localized to the phagosome at the initiation of phagocytosis and redistributed to the cytosol after closure. Both probes slowed phagocytosis. These results indicate that $PI(3,4,5)P_3$ is the essential 3' phosphoinositide in FcR-mediated phagocytosis. Its levels are regulated by the exclusion of PTEN and the simultaneous recruitment of PI3K and SHIP-1 to the phagosome. These results further indicate that the changing profiles of 3' phosphoinositides on phagosomal membranes are regulated by mechanisms for enzyme deactivation, rather than by sequential enzyme recruitment.

469

**Targeting of the Small GTPase ARL10c to the Lysosomal Membrane**

I. M. Hofmann, S. Munro; Cell Biology, MRC Laboratory of Molecular Biology, Cambridge, United Kingdom

ARF-like proteins (ARLs) are small GTPases with homology to ADP-ribosylation factors (ARFs). Whereas ARFs are important regulators of membrane traffic, ARLs seem to be involved in processes as diverse as vesicle transport (ARL1) and tubulin folding (ARL2). To examine the function of the human ARLs more closely, we started investigating their intracellular localization. ARL1, ARL5 and ARL8 localize to the Golgi, ARL4, ARL4L and ARL7 to the plasma membrane and ARL10c to lysosomes. ARL10c is targeted to the lysosomal membrane by a mechanism unusual for the ARL-proteins. Conventionally, membrane localization of ARF- and ARL-proteins is conferred by both an N-terminal myristate and an N-terminal amphipathic helix, which insert into the lipid bilayer. Instead of the N-terminal myristate ARL10c is N-terminally acetylated, and this acetyl-group is necessary for its lysosomal localization. In addition, mutation of hydrophobic residues in the amphipathic helix of ARL10c abolishes membrane localization of ARL10c. This indicates a function of the N-terminal helix in membrane attachment similar to other ARFs/ARLs. Thus, ARL10c is targeted to the lysosomal membrane by both an N-terminal acetyl-group and the amphipathic helix. Overexpression of ARL10c results in a redistribution of lysosomes towards the cell periphery. Furthermore, ARL10c seems to control lysosomal transport by increasing frequency and run length of transport events and by decreasing pauses and small movements. This suggests a role for ARL10c as positive regulator of lysosomal transport.

470

**Autocrine Motility Factor Receptor, a Ubiquitin E3 Ligase, is Monoubiquitylated and Regulates p97/VCP AAA ATPase ubiquitylation**

P. St-Pierre,[1] T. Dang,[1,2] I. Nabi[1]; [1]Department of Cellular and Physiological Sciences, University of British Columbia, Vancouver, BC, Canada, [2]Département de Pathologie et de Biologie Cellulaire, Université de Montréal, Montréal, PQ, Canada

Activation of autocrine motility factor receptor (AMFR) by its ligand, AMF, is associated with cellular transformation and protection from apoptosis and stimulates tumor cell motility and angiogenesis. AMFR is also a multimembrane spanning ubiquitin E3 ligase involved in endoplasmic reticulum-associated degradation (ERAD) whose cytoplasmic domain contains both a RING finger and a CUE domain. The p97/VCP AAA ATPase regulates ubiquitylation and proteasomal targeting of substrates for ERAD and has been reported to be associated with the AMFR cytoplasmic tail. Here we report two monoubiquitylated forms of AMFR whose expression is dependent on the integrity of the RING finger domain. In contrast, disruption by point mutations of the CUE domain function does not significantly impair monoubiquitylation of AMFR. p97 coimmunoprecipitates with AMFR and exhibits partial colocalisation to the smooth endoplasmic reticulum with AMFR. Expression of AMFR promotes monoubiquitylation of various substrates including p97. AMFR-p97 interaction is not affected by disruption by point mutation of either the RING or Cue domains while monoubiquitylation of p97 is RING finger but not Cue domain dependent. The RING finger domain of AMFR is therefore implicated in monoubiquitylation of both AMFR and p97. Supported by the CIHR.

471

**Delta Aminolevulinic Acid Dehydratase Regulates Proteasome Activity**

F. Bardag-Gorce,[1] A. Banerjee,[2] J. Li,[1] B. A. French,[1] S. W. French[3]; [1]Pathology, LABiomed at Harbor-UCLA Med Center, Torrance, CA, [2]Department of Pharmaceutical Sciences, Wayne State University, Detroit, MI, [3]Pathology, Harbor-UCLA Med Center, Torrance, CA

The proteasome interacts with a large number of proteins in order to perform specific functions. The focus of this study is to examine the proteasome interaction with Delta aminolevulinic acid dehydratase (ALAD), which is involved in the heme biosynthesis pathway. This enzyme interacted and was co-purified with the 20S proteasome using several chromatographic purification steps. Tryptic digestion was used followed by ESI mass spectrometry analysis to identify this 20S interacting protein as ALAD. When the 26S proteasome was isolated using density-gradient centrifugation, ALAD stained positive in Western blot of the 26S proteasome fraction. This result indicated that ALAD interacts with the proteasome. However proteasome inhibition in vivo achieved by giving PS-341 to the rats, did not change the ALAD protein level in liver

homogenates. When mice are fed diethyl 1,4-dihydro-2, 4,6 trimethyl-3,5-pyridine dicarboxylate (DDC), they develop protoporphyria due to the disruption of heme synthesis. In this model the ALAD protein level was decreased and the proteasome beta5 subunit (subunit carrier of the chymotrypsin-like activity) level was up regulated. This data supports the hypothesis that ALAD, as an important enzyme for heme synthesis, is also important as a proteasome modulator, which is consistent with the double function of the ALAD protein. Thus ALAD may function as an important regulator of proteasomal activity. Supported by NIH/NIAAA Grants 8116 and GM-59467.

**Evidence for Metabolic Coupling of Peroxisomes and Lipid Bodies**

D. Binns,[1] T. Januszewski,[2] Y. Chen,[3] Y. Zhao,[3] C. Gilpin,[2] K. Chapman,[4] J. M. Goodman[1]; [1]Pharmacology, University of Texas Southwestern Medical Center, Dallas, TX, [2]Cell Biology, University of Texas Southwestern Medical Center, Dallas, TX, [3]Biochemistry, University of Texas Southwestern Medical Center, Dallas, TX, [4]Biological Sciences, University of North Texas, Denton, TX

We and others have observed close physical interactions between peroxisomes and lipid bodies. In the yeast Saccharomyces cerevisiae growing on oleic acid (a condition in which both peroxisomal and lipid body metabolism is induced) fluorescence microscopy shows that most peroxisomes associate with lipid bodies. Thin section electron microscopy reveals that peroxisomes wrap around lipid bodies and even extend processes into their cores. Purified lipid bodies are enriched in peroxisomal enzymes that catalyze fatty acid beta-oxidation, but not other peroxisomal proteins, suggesting that "peroxisomal" beta oxidation is tightly coupled to the metabolism of lipid bodies, a source of fatty acids. We describe novel morphological structures within lipid bodies we term "gnarls",that may represent accumulations of fatty acids. Gnarls are particularly abundant in strains containing peroxisomes that are unable to metabolize fatty acids, yet they are less developed in a strain entirely lacking in peroxisomes. We propose that peroxisomal contact with lipid bodies stimulates the generation of fatty acids at the lipid body, which are then utilized by peroxisomal enzymes embedded in the lipid body or adjacent to it. If peroxisomes are defective, fatty acids accumulate to create the gnarls.

**The Peroxisomal Membrane Protein, Pex16p, is Involved in the Formation Peroxisomes at the Endoplasmic Reticulum**

P. K. Kim,[1] R. T. Mullen,[2] J. Lippincott-Schwartz[1]; [1]Cell Biology & Molecular Biology, NICHD/NIH, Bethesda, MD, [2]Molecular and Cellular Biology, University of Guelph, Guelph, ON, Canada

Peroxisomes are small, membrane-bound organelles present in almost all eukaryotic cells. Although defects in peroxisome biogenesis are involved in various diseases, the molecular mechanisms involved in peroxisome biogenesis are poorly understood. In yeast, plants, and mammals, evidence exists for both fission and *de-novo* formation of peroxisomes. However, whether the *de-novo* assembly of peroxisomes is dependent on the endoplasmic reticulum (ER) or some other endomembrane system is still a matter of debate. To examine the possible role of the ER in peroxisome biogenesis, the cellular localization of Pex16p (a peroxisomal membrane protein/peroxin essential for peroxisome biogenesis) was examined using cell-free targeting assays and confocal microscopy techniques with green fluorescence protein (GFP) chimeras. We show that Pex16p is co-translationally targeted to the ER *in vitro*, in contrast to the reported post-translational targeting of other peroxisomal proteins. We show also that a Pex16-GFP fusion protein localizes to both ER and peroxisomes in COS7 cells, but only to ER in *pex19* mutant cells, which lack peroxisomes. A modified version of Pex16-GFP fusion protein containing a *bona fide* ER targeting signal sequence at its amino-terminus also localizes to both ER and peroxisome in COS7 cells, and can functionally complement *pex16* mutant cells. These data suggest that the ER-targeted version of Pex16-GFP is sufficient for the production of new peroxisomes and that the machinery responsible for peroxisomal import is derived from the ER. Consistent with this premise, time-lapse imaging of live cells revealed that a Pex16-Photoactivatable-GFP fusion protein that was photoactivated while in the ER was localized eventually to peroxisomes. Overall, these data demonstrate the ER origin of mammalian Pex16p and support an emerging model for peroxisome biogenesis in evolutionary diverse organisms wherein the organelle forms *de-novo* from the ER.

474

**Cloning and Characterization of Peroxisomal Membrane Protein-70 Throughout *Xenopus laevis* Development**

C. A. Cooper,[1] P. A. Walton,[2] S. Damjanovski[1]; [1]Biology, University of Western Ontario, London, ON, Canada, [2]Anatomy and Cell Biology, University of Western Ontario, London, ON, Canada

Peroxisomes are ubiquitous single membrane bound organelles, which are essential for eukaryotic cell function. They facilitate the chemical breakdown of fatty acids through the process of β-oxidation. Peroxisomal membrane proteins (PMPs) are of particular interest as defects in these proteins result in improper peroxisome function. Peroxisomes have been characterized in several organs and tissues and play important roles in cell senescence. Little is known however, about their role in development. Furthermore, there is no research to date concerning how peroxisomes are associated with the complex physiological changes that occur during frog metamorphosis. In this study, *Xenopus* PMP-70 was cloned and characterized and its spatial and temporal expression pattern analyzed throughout early development and metamorphosis. The amino acid sequence of *Xenopus* PMP-70 shows 92% similarity to mammalian PMP-70. Embryo microinjections of a tagged GFP directed to peroxisomes resulted in the localization of GFP in aggresomes prior to embryonic stage 22. This suggests a lack of functional peroxisomes in early development, a finding confirmed by RT-PCR and whole mount *in situ* analysis. PMP-70 was predominantly localized following stage 34 to the developing eye, pharyngeal arches, and dorsal neural tissues. This finding is consistent with semi quantitative RT-PCR which shows a steady increase in PMP-70 RNA throughout development. Interestingly, PMP-70 RNA levels remain relatively constant during the metamorphosis of the heart, limb and tail. In the liver however, PMP-70 RNA increases dramatically at the peak of metamorphosis. This is at a time when fatty acid stores are being metabolized at an increased rate as tadpoles undergoing metamorphosis do not take in food. Although peroxisomes continue to be implicated in cell senescence, these findings suggest important roles for peroxisomes during the development of specific tissues and organs.

**Intracellular Redistribution of Catalase Provides Increased Cellular Protection Against Non-peroxisomal Oxidative Stress**

A. Pellicoro, F. A. J. van den Heuvel, K. Landman, K. N. Faber; Gastroenterology and Hepatology, UMCG, Groningen, The Netherlands

Background & aims: Catalase is a peroxisomal enzyme that detoxifies $H_2O_2$ produced by peroxisomal oxidases. Catalase is also regarded as an antioxidant enzyme that protects cells against non-peroxisomal oxidative stress. Human cells are continuously exposed to oxidative stress and there

is ample evidence that reactive oxygen species are a key factor in development of aging. Moreover, oxidative stress is an important contributor to the pathology of a variety of diseases. Catalase may redistribute to the cytosol in aging cells or when cells are exposed to $H_2O_2$. We determined the effect of intracellular redistribution of catalase on protection of cells against exposure to $H_2O_2$. Methods: Cells from the human hepatoma cell line HepG2 were grown in the presence of variable amounts of $H_2O_2$, with or without the addition of the catalase inhibitor 3-aminotriazol (3-AT). Sytox green was used to visualize (by fluorescence microscopy) and quantify (by fluorometry) necrosis. HepG2-derivative cell lines were generated that overexpress peroxisomal or nuclear catalase. RNA interference (RNAi) was used to 1) decrease expression of catalase or 2) disrupt peroxisomal targeting of catalase by reducing expression of the signal receptor, Pex5p. Real time RT-PCR, Westernblot analyses and immunohistochemistry were used to determine mRNA levels, protein levels or the subcellular location of catalase, respectively. Results: 3-AT and RNAi-reduction of catalase strongly sensitized HepG2 cells for $H_2O_2$-induced necrosis. Both nuclear and peroxisomal overexpressed catalase gave significant protection against $H_2O_2$ stress. The nuclear catalase was more protective than the native one. RNAi-reduction of Pex5 resulted in cytosolic catalase. These cells showed an increased protection against extra-peroxisomal $H_2O_2$. Conclusions: Redistribution of catalase to the cytosol provides increased cellular protection against extracellular oxidative stress. This may be a functional adaptation to face increased oxidative stress during aging or disease.

## Gene Structure and Expression (476-495)

### Transcriptional Regulation of the Mammalian ATP Synthase Alpha-Subunit Gene

G. A. Breen, A. Alam, R. Pittman; Molecular and Cell Biology, University of Texas at Dallas, Richardson, TX

Mitochondrial biogenesis is a highly regulated and coordinated process. Our laboratory has been studying the transcriptional regulation of the nuclear gene that encodes the α-subunit of the mammalian mitochondrial ATP synthase complex (*ATPA*). We have now identified a number of regulatory factors which regulate the expression of the *ATPA* gene. For example, we have determined that the transcription factor, upstream stimulatory factor 2 (USF2), binds to an E-box element (CANNTG) in the upstream promoter of the *ATPA* gene and stimulates expression of this gene. We have also determined that USF2 activates the *ATPA* gene through binding to an initiator element in the core promoter. Furthermore, we have determined that the transcriptional coactivator, p300, interacts functionally with USF2 to activate the *ATPA* gene. We have also identified a negative regulatory factor, COUP-TFII/ARP-1, which represses the expression of the *ATPA* gene. Furthermore, we have determined that COUP-TFII/ARP-1 inhibits the USF2-mediated activation of the *ATPA* gene promoter. Electrophoretic mobility shift assays revealed that COUP-TFII/ARP-1 and USF2 compete for overlapping binding sites in the upstream promoter of the *ATPA* gene. Recently, we have demonstrated a role for the coactivator, PGC-1α, in the transcriptional regulation of the *ATPA* gene. It is likely that the net expression of the *ATPA* gene will result from the relative concentration and affinity of these regulatory factors (and probably other factors) expressed in a given physiological state. These factors might play important regulatory roles linking changes in expression of the *ATPA* gene with changes in cellular energy needs.

### Transcriptional Effect of Oxidative Stress in Normal Human Keratinocytes using Low Density cDNA Microarray

M. Bonnet-Duquennoy, K. Lazou, S. Talbourdet, S. Schnebert, R. Kurfürst; Life Sciences Dpt, LVMH Recherche, St Jean de Braye, France

Skin is a major target of oxidative stress due to reactive oxygen species (ROS) that originate in the environment and in the skin itself. ROS are generated during normal metabolism and cause oxidative alterations on cell constituents causing development of cutaneous disorders as ageing and more serious lesions as cancer. Although ROS play a crucial role on skin regulation, their biological targets and pathogenic mode of action are still not fully understood. In order to study mechanisms of oxidative stress response, we developed a sensitive, rapid and quantitative microarray method. We have chosen OLISA™ (OLIgo Sorbent Array) technique, an oligonucleotide microarrays developed by bioMérieux. The gene panel screened involved 105 skin-related genes coding for proteins associated with cell death, proliferation, anti-oxidant defense mechanisms, signal transduction, epidermal structure and differenciation. With this technique, gene expression was assessed in normal human keratinocytes at the basal level and after a hydrogen peroxide treatment (25µM). We showed that more than 85 of genes (80%) were detected in the cells studied. We observed major modification at transcriptional level between 6 and 24 hours after hydrogen peroxide treatment. Moreover, we showed that 30% of detected genes had differing expression levels. Focusing on anti-oxidant genes, 75% of detected genes were significantly regulated. Significant increases in metallothionein, thioredoxin and SOD1 expression were observed showing induction of defense mechanism by oxidative stress. A marked difference was observed in the decreased gene expression of p63 and p73, transcriptional factors involved on cell cycle regulation and keratinocyte differentiation suggesting alteration of these mechanisms by oxidative stress. In conclusion, this method associated with human keratinocyte culture provides a good strategy for understanding physiological response to oxidative stress in epidermis and studying new protective molecules.

478

### Protein Folding Information in Nucleic Acids which is Not Present in the Genetic Code

J. C. Biro; Homulus Foundation, San Francisco, CA

**Background:** All the information necessary for protein folding is supposed to be present in the amino acid sequence. It is still not possible to provide specific ab initio structure predictions by bioinformatical methods. It is suspected that additional folding information is present in protein coding nucleic acid sequences, which is not represented by the known genetic code. **Results:** Nucleic acid subsequences comprising the 1st and/or 3rd codon residues in mRNAs express significantly higher free folding energy (FFE) than the subsequence containing only the 2nd residues ($p$<0.0001, $n$=81). This periodic FFE difference is not present in introns and therefore it is a specific physico-chemical characteristic of coding sequences and it might contribute to unambiguous definition of codon boundaries during translation. The FFE in the 1st and 3rd residues is additive, which suggests that these residues contain a significant number of complementary bases and contribute to selection for local RNA secondary structures in coding regions. This periodic, codon-related structure-forming of mRNAs indicates a connection between the structure of exons and the corresponding (translated) proteins. The folding energy dot plots of RNAs and the residue contact maps of the coded proteins are indeed similar. Residue contact statistics using 81 different protein structures confirmed that amino acids that are coded by partially reverse and

complementary codons (Watson-Crick (WC) base pairs at the 1st and 3rd codon positions and translated in reverse orientation) are preferentially co-located in protein structures. **Conclusions:** The preferentially (specifically) interacting amino acids are coded by partially complementary codons, which strongly supports the connection between mRNA and the corresponding protein structures and indicates that there is protein folding information in nucleic acids that is not present in the genetic code.

**Characterization of the Luteinizing Hormone beta-Subunit Precursor Protein cDNA in the Rabbit**

O. Suzuki, M. Koura, Y. Noguchi, K. Takano, K. Uchio-Yamada, J. Matsuda; Laboratory of Experimental Animal Models, National Institute of Biomedical Innovation, Ibaraki-shi, Japan

To elucidate the molecular basis of efficient superovulation in the rabbit, we determined the cDNA sequences of the luteinizing hormone β-subunit (LHB) for three breeds of rabbit (Japanese White, JW; New Zealand White, NZW; and Dutch Belted, Dutch) using a combination of 5'- and 3'-rapid amplification of cDNA ends (RACE) with pituitary cDNA libraries, and compared them with those of other mammals. The RACE experiments revealed that the LHB cDNA of all three breeds were the same length (524 bp from the 5'-end to the polyA site), with a putative AATAAA polyadenylation signal sequence at positions 505 to 510. Their 426-bp-long coding sequences had a higher GC content (>73%) than that of other mammals (~65%). The deduced amino acid sequence of JW, which was 141 residues long, was exactly the same as that of NZW, but differed from that of Dutch at two positions. Phylogenetic analysis of the deduced amino acid sequences of the three rabbits' LHB and those of laboratory and domestic animals suggest that the rabbit stands in a phylogenetically intermediate position between rodents and domestic animals, as we showed in a similar analysis of FSH β-subunits at the 2004 ASCB meeting. These unique features of rabbits might be related to their unique reproductive endocrine system, copulatory ovulation. The cDNA sequence of JW LHB has been deposited in GenBank (accession number: AY614703).

**SUMO Modification and Acetylation Regulate the Activity and Stability of the ETS Transcription Factor, Myeloid Elf-1 like Factor**

H. Nakamura,[1] M. S. Suico,[1] Z. Lu,[1] H. Saitoh,[2] T. Shuto,[1] M. Nakao,[2] H. Kai[1]; [1]Molecular Medicine, Kumamoto University, Kumamoto, Japan, [2]Regeneration Medicine, Kumamoto University, Kumamoto, Japan

Myeloid elf-1-like factor (MEF) or ELF4 is an ETS protein, which has a wide distribution in hematopoietic and non-hematopoietic tissues. MEF is known to activate the promoters of granulocyte macrophage colony-stimulating factor and interleukin-3 and the transcription of perforin in NK cells. It also up-regulates the basal expression of the anti-microbial peptides, lysozyme and human beta defensin-2. We also previously demonstrated that MEF is a candidate tumor suppressor gene in the X chromosome. The numerous target genes of MEF and its biological functions signify the importance of this Ets transcription factor. Therefore, we attempted to investigate the regulation of MEF protein. Here we show that MEF is modified by conjugation with SUMO-1 (small ubiquitin-related modifier) both in vitro and in vivo at lysine 657. This modification led to the decrease of MEF activity on its target gene, lysozyme, as proven by reporter assays and RT-PCR. These data suggest that SUMO negatively regulates MEF. Another important modification that commonly occurs in histones and transcription factors is acetylation. We demonstrate here that MEF is acetylated and the functional consequence of this modification is the enhancement of MEF protein stability. Upon treatment with TSA, an inhibitor of histone deacetylase complex, MEF protein expression was enhanced. A time-course treatment with cyclohexamide, an inhibitor of de novo protein synthesis, confirmed this result. These findings provide important information on the modifications that occur on MEF and how these modifications affect its stability and activity.

**PLZF is a Target of the Transcriptional Repressor CDP in the Intestinal Epithelium**

I. Fréchette, F. Boudreau; Anatomy and Cell Biology, University of Sherbrooke, Fleurimont, PQ, Canada

We recently demonstrated the role of the transcription factor CDP (*CCAAT-Displacement protein*) in colonic repression of SI (Sucrase-Isomaltase) gene during development. It is well documented that SI becomes re-expressed during the first steps of colorectal cancer. However, the role of CDP in the colonic epithelium has not been yet established. In order to gain a better comprehension of CDP intestinal function, we sought to identify additional colonic transcriptional targets of CDP. We performed a microarray analysis utilizing CDP mutant mice and identified PLZF (Promyelocytic Leukemia Zinc Finger) as being upregulated in the colon of these mutant mice. Since PLZF is a transcriptional repressor implicated in the maintenance of stem cells in other systems, we undertook to verify whether CDP could modulate PLZF gene expression. First, we correlated expression of CDP and PLZF in human colorectal cancer cell lines. A Western blot analysis showed weak expression of CDP in cancer cells as compared to normal colonocytes. In contrast, PLZF was expressed in the majority of cancer cells but remained undetectable in normal colonocytes. A computer analysis of the PLZF gene predicted 21 potential interaction sites for CDP. We chose to investigate a 3 kb region upstream to the translation initiation site. A gel shift experiment confirmed the presence of five CDP-interacting sites within this region. Cotransfections of 293T cells with a CDP expressing vector and a PLZF-luciferase reporter plasmid resulted in the reduction of PLZF transcriptional activity. Finally, overexpression of CDP in the human colorectal cancer Caco2 cell line resulted in reduction of PLZF expression. Overall, these results suggest that PLZF is a direct target of CDP in the intestinal epithelium. Further studies will be necessary to unravel the biological significance of this genetic interaction.

**Zebrafish Contain Two Genes and Two mRNAs for AP endonuclease 1**

Y. Wang, L. F. Melo, P. R. Strauss; Biology, Northeastern University, Boston, MA

Abasic sites in DNA are produced spontaneously and by genotoxic agents. Repair is initiated by AP endonucleases, highly conserved proteins from *E. coli* to man. Since knockout of APendo is an embryonic lethal in mice, we are investigating the role of APendo in embryonic development in zebrafish *Danio rerio*. Zebrafish cDNA for APendo encodes a protein with 310 amino acids and 78% homology to mammalian APendo 1. The greatest divergence is in the amino terminus, residues 1 through 40. The expressed protein has a Km of 100 nM and a turnover number of 4 $s^{-1}$, similar to the human protein. The zebrafish genome contains two copies of a gene encoding AP endo. One copy, found on chromosome 4 (Sanger

database) consists of 4 introns ( 80-1128 bp) and 5 exons, the first of which is untranslated. Distribution of introns and exons is similar to that of the human gene. The second copy contains the same coding sequence but has no introns and lacks 700 bp found in the 3' UTR of the other copy. This copy could be a pseudogene, the result of a retrotransposon or a functional gene. Both adult and embryonic zebrafish contain two mRNAs for APendo. The larger one, which is 2.1 kb, contains the unique 700 bp found in the gene located on chromosome 4. The smaller 1.4 kb copy is missing the 700 bp found on the larger form. In short, zebrafish have two genes for APendo that are similar to the one in the human genome and two mRNAs; the encoded protein is very highly homologous to other vertebrate APendos. Supported by NIH CA72702.

**The Role of *Zfpm-1* on *in vitro* Erythropoiesis of Human Cord Blood CD34$^+$ Cells**

H. Yang,[1] S. Kim,[1] C. Jin,[1] K. Cho,[1] H. Park,[1] K. Chung,[1] E. Cho,[1] B. Park,[1] J. Hur,[2] T. Lee[1]; [1]Dept. of Oral Biochemistry, School of Dentistry, Chonnam National University, Gwangju, Republic of Korea, [2]Eden Hospital, Gwangju, Republic of Korea

Erythropoiesis is a complex multistage process for the differentiation of hematopoietic stem cells to mature erythrocytes. However, the molecular basis governing the functional behavior of erythropoiesis is still unclear. Previous results suggest that Prx$^{-/-}$ mice have hemolytic anemia. The EPO level in Prx II$^{-/-}$ mice was twice that of the Prx II$^{+/+}$ mice. Moreover, the number of proerythroblasts was higher in the bone marrow of Prx$^{-/-}$ mice than in Prx II$^{+/+}$ mice. There was a slightly reduced number of Lin$^-$c-kit$^+$Sca-1$^+$ cells, but there was a higher number of TER-119$^+$ cells in the Prx II$^{-/-}$ mice. This study examined the differential expression profiles using a cDNA microarray technique with bone marrow cells in Prx$^{+/+}$ and Prx$^{-/-}$ mice to determine the regulatory factors in the erythropoiesis of CD34$^+$ hematopoietic stem cells. 136 genes including 66 EST genes were differentially expressed in bone marrow cells of the Prx$^{-/-}$ and the Prx$^{+/+}$ mice. In this present, we pointed to 6 genes of RNA & protein binding group in 70 genes except 66 EST genes among differential expressed 136 genes. In order to verify functions of these interested candidates to erytheopoiesis, we established human CD34$^+$ cell culture system by using human umbilical cord blood. At day 7 of *in vitro* erythropoiesis, 4 genes, *eIF3-p44, hnRNPH1, G3bp, and Zfpm-1* were initially up-regulated and then dramatically down-regulated. However, 2 genes, *DJ-1* and *Rbm3* weren't. *Zfpm-1* siRNA treated cells contained 20% more GPA$^+$ cells than unrelated siRNA treated cells, and showed repressed expression of the hematopoietic transcription factors, *c-myc* and *c-myb*, but not *GATA-1*. These results suggest that the repression of *Zfpm-1* accelerates erythropoiesis on *in vitro* culture system. This work was supported by the Korea Research Foundation Grant funded by Korean Government (R08-2003-000-10271-0).

**The MEK/ERK Pathway Regulates Osteoclast Survival Through Egr1 and Egr2**

E. W. Bradley, M. J. Oursler; Endocrine Research Unit, Mayo Clinic, Rochester, MN

Reducing osteoclast numbers through targeting survival pathways may provide future therapeutic targets to slow pathological bone loss. We have shown that chemical inhibition of MEK increases osteoclast apoptosis. We therefore sought to identify downstream targets of MEK-mediated osteoclast survival. Using microarray technology, we identified two genes, Egr1 and Egr2, functioning downstream of MEK in osteoclasts. Egr1 and Egr2 expression was inhibited by chemical inhibition of MEK1/2. Further, over-expression of constitutively active MEK1 increased expression of Egr1 and Egr2. These data confirmed that Egr1 and Egr2 are downstream targets of the MEK/ERK pathway. Over-expression of Nab2, the co-repressor for Egr1 and Egr2, increased osteoclast apoptosis. Since Nab2 blocks both Egr1 and Egr2, we determined the roles of these early response genes in osteoclast survival. Over-expression of Egr1 did not repress osteoclast apoptosis, leading to the conclusion that Egr2 is the downstream effector of MEK/ERK in promotion of osteoclast survival. To determine whether Egr1 could replace Egr2 in supporting osteoclast survival, we chemically blocked MEK1/2 and determined the effect of Egr1 over-expression. Over-expression of Egr1 bypassed the effects of MEK 1/2 inhibition and decreased osteoclast apoptosis. Thus Egr1 could replace Egr2 in promoting osteoclast survival. These data demonstrate that, although Egr1 is not the downstream effector of osteoclast survival, it can substitute for Egr2 when expression is blocked by inhibiting MEK signaling. To determine whether additional targets were important in MEK-mediated osteoclast survival, we compared impacts of MEK inhibition, Nab2 over-expression to inhibit Egr family members, and combined MEK and Nab2 over-expression on osteoclast survival. When compared to chemical inhibition of MEK1/2 alone, over-expression of Nab2 in combination with MEK1/2 inhibition did not further increase osteoclast apoptosis. These data support that MEK-mediated osteoclast survival is through increased expression of Egr family members.

**Dynamic Behavior of Episomal DNA within the Nucleus**

J. Z. Gasiorowski, D. A. Dean; Pulmonary and Critical Care Medicine, Northwestern University, Chicago, IL

The nucleus controls many functions and interactions that are only vaguely understood at this time. Our aim is to study and characterize the mechanisms and interactions that influence episomal transgene expression within the nucleus. Contrary to widespread belief, our studies show that episomal DNA is a dynamic molecule within the nucleus. We found that plasmid DNA microinjected directly into a nucleus moves into a speckled pattern and occupies less nuclear volume than BSA, dextran, or other inert injected molecules after 4 hours. In addition, a plasmid that contains eukaryotic regulatory sequences and actively transcribes a transgene condenses into a few select areas of the nucleoplasm and occupies less nuclear volume than a bacterial vector. This suggests that episomal DNA moves in a sequence dependent manner by some means other than diffusion. We have also found that plasmids microinjected into nuclei traffic to specific subnuclear domains depending on their sequence. Our experiments show that plasmids with polymerase II regulatory elements will target to nuclear spliceosome regions, while plasmids with the polymerase I promoter often traffic into nucleoli. Alteration of episomal sequences can potentially be used to target transgenes not just into the nucleus, but also to exact regions of the nucleoplasm where expression can be maximized. Finally, we have found that directed intranclear movement of episomes into specific subnuclear domains correlates to changes transgene expression. Further elucidation of intranuclear plasmid trafficking behavior may lead to a better understanding of transgene expression that could improve basic laboratory techniques as well as clinic therapies.

**Ligand Activation of the Androgen Receptor Downregulates the Expression of E-cadherin in Breast Cancer Cells**

Y. N. Liu,[1] H. Z. Lee,[2] J. H. Chen[3]; [1]Graduate Institute of Medical Sciences, Tzu chi University, Hualien, Taiwan Republic of China, [2]Department

of Life Science and Institute of Biotechnology, Nation Dong Hwa University, Hualien, Taiwan Republic of China, [3]Graduate Institute of Molecular and Cellular Biology, Tzu chi University, Hualien, Taiwan Republic of China

Metastasis is a multistep process through which primary cancer cells spread to the secondary site in distant organs. To understand the mechanisms of metastasis we focused on the studies of the regulation of E-cadherin gene expression. Previously we found HNF3α could enhance human E-cadherin gene expression thus reducing the migration ability of metastatic breast carcinoma cell lines MDA435 and MDA231. In that study we noticed there was a regulatory element that exerts suppressive effect on the human E-cadherin gene expression. Gel mobility shift assay indicated this regulatory element may be a binding site for androgen receptor (AR), a member of the steroid receptor superfamily that belongs to a larger family of ligand-dependent transcription factors. Co-transfection of human full length AR cDNA with E-cadherin reporter construct showed the repression of transcription in the present of AR ligand, dihydrotestosterone (DHT). Co-transfection of HDAC1 with AR plus DHT showed the synergistic downregulatory effect on E-cadherin regulatory sequence. These data suggested AR may cooperate with HDAC1 and play suppressed effect to downregulate the E-cadherin expression in breast cancer cells. The effect of AR plus DHT on the migration ability and expression of E-cadherin on the cell membrane of MCF7 and T47D breast cancer cells will be presented.

**What Are Human Kao-nashi (face-less) Genes?**

N. Shimizu,[1] S. Asakawa,[1] T. Sasaki,[1] M. Furutani-Seiki,[2] H. Kondoh,[2] A. Shimizu[1]; [1]Molecular Biology, Keio University School of Medicine, Tokyo, Japan, [2]SORST, Kondoh Research Group, JST, Japan

The Human Genome Project has provided the DNA sequences of 3 billion base pairs and identified over 23,000 protein-coding genes. However, many of these protein-coding genes are not fully proven by experimental evidences. In general, proteins with known motifs are readily classified, but substantial numbers of protein have no obvious motifs in their sequences. We designated these genes/proteins without obvious motifs as KAO-NASHI (Face-less) and initiated a project to unveil their face (kao) by comparative genomics and knockdown analysis using Medaka (a small teleost fish) as animal model. We extracted 1,000 KAO-NASHI genes from 23,000 genes in the human genome using motif analysis by InterPro, homology search by BLAST and document search by PubMed. In order to unveil the functions of these KAO-NASHI genes, we decided to use Medaka (Oryzias latipes) because it is easy to obtain embryos and to observe subtle changes in the organs or anatomical structure. We have identified Medaka orthologs for over 60% of human KAO-NASHI genes using the Medaka EST and whole genome shotgun sequence databases. Developing stage of Medaka embryo was divided into 39 stages based on the diagnostic features of the developing embryos. We extracted mRNA separately from each stage and used for expression analysis of KAO-NASHI genes. Many of the initial 100 genes showed ubiquitous expression during development, but several genes showed stage-specific expression. These expression profiles are invaluable for initial functional annotation. Furthermore, we have applied the gene knockdown strategy using Morpholino oligonucleotides (MOs) injection to obtain information on the effects of a drastic reduction in expression of the target gene. In fact, we have observed some morphological changes during Medaka development after knockdown of several KAO-NASHI genes.

**Transgenic pS2/TFF1 Promoter-Rats: An Animal Model to Study in vivo transcriptional Mechanisms and Gene Regulation**

E. Zhong, H. Bohnemeier, M. Paul, G. Schoenfelder; Inst. of Clinical Pharmacology and Toxicology, Charité-Universitaetsmedizin Berlin, Berlin, Germany

Objective: The human pS2/TFF1 belongs to the family of trefoil peptides. TFF1 locates mainly in the cytoplasm of epithelial cells. The function of the TFF-peptides is not well understood. It was shown that they play a major role in maintaining the surface integrity epithelial cells. pS2/ TFF1 is involved in mucin polymerization, cell motility, cell proliferation and differentiation. TFF1 expression can highly be stimulated by estrogens. Several transcription factors, regulatory proteins and epigenetic factors regulate the cell-specific expression of the TFF1 gene. But, function and transcriptional mechanisms for TFF1 regulation in the female reproductive system remain unclear. Therefore, we established a transgenic rat with a TFF1 promoter-luciferase-construct to elucidate function and regulation of TFF1 under the in vivo situation. Methods and Results: Reporter assays using a TFF1 promoter-reporter, again, revealed dose-dependent response in MCF-7 cells with a series of 17beta-estradiol concentrations. After in vitro tests, we established a transgenic homozygous rat strain on a Sprague-Dawley background. PCR analysis showed that the construct was successfully integrated in the rat genome. Luciferase activity and real-time in vivo imaging of the reporter gene revealed highest transcriptional activity of the pS2-promoter in brain, uterus and vagina. Our realtime-RT-PCR analysis and immunohistochemistry confirmed transcriptional regulation of the pS2/TFF1-promoter. Conclusion: We successfully established the first TFF1 promoter-luciferase transgenic rat model to study function, regulation and morphological effects of TFF1 in a living animal model. With that animal model we are now able to study the impact of estrogens on the transcriptional regulation of TFF1 in different organs especially under in vivo conditions.

***Saccharomyces cerevisiae* Cells in Stationary-phase Cultures Respond to Oxidative Stress Through a Rapid Release of Sequestered mRNA**

A. D. Aragon,[1] G. A. Quinones,[1] E. V. Thomas,[2] S. Roy,[3] M. Werner-Washburne[1]; [1]Biology, University of New Mexico, Albuquerque, NM, [2]Sandia National Laboratories, Albuquerque, NM, [3]Computer Science, University of New Mexico, Albuquerque, NM

*Saccharomyces cerevisiae* cells, growing in rich medium, cease cell division and enter into stationary-phase when carbon sources are exhausted from the medium, typically after 7 days. Stationary phase is extremely important in health and disease, thus, understanding how cells survive and respond in this phase is vital. The objective of this study was to assess the ability of cells in stationary-phase cultures to respond, at the level of mRNA abundance, to oxidative stress. In response to oxidative stress (50 μM menadione final concentration) without addition of a carbon source, 1100 mRNAs exhibited significant increases within 30 minutes. To determine how quickly these transcripts appeared, a newly developed automated sampling device was used to harvest two additional time courses, with one-minute and ten-second intervals, respectively. Analysis of these time courses reveled that the increase in transcript abundance occurred within 80 seconds. There was an overlap of approximately 800 transcripts exhibiting increased abundance across all three time courses. To determine if this response was due to new transcription, an RNA polymerase II mutant, *rpb1-1,* was tested under non-permissive conditions. A similar increase in transcript abundance was observed, indicating that new transcription was not required. To test whether transcripts were in solution but not polyadenylated, mRNA was analyzed by qRT-PCR and

results indicated the transcripts were not present in isolated total RNA. Finally, cell lysates were incubated with and without several proteases, and microarray analysis showed a dramatic increase in soluble mRNA in treated samples from cells in stationary-phase cultures but not exponential cultures. Results indicate that cells in stationary-phase cultures contain a large number of intact, mature mRNAs that appear to be sequestered in protein-mRNA complexes that can be released rapidly in response to stress.

**DNA and mRNA Regulation of Ferritin-L is Coordinated by Hemin**

K. J. Hintze, E. C. Theil; Center for BioIron, Children's Hospital of Oakland Research Institute, Oakland, CA

Cells depend on Fe and for key reactions, in spite of potential catalysis of reactive oxygen species. Therefore, cellular Fe balance is tightly regulated; crucial to this regulation is ferritin, a highly conserved, protein nanocage that concentrates up to 4000 Fe atoms/ferritin protein overcoming the $10^{14}$-fold gradient between Fe solubility and cellular needs. In animals, ferritin is a 24mer, assembled from two gene products, ferritin-H (ubiquitous throughout nature) and L (FTL, specific to animals). Fe-overload increases FTL transcription and Fe and $O_2$ are known to increase translation. Since interactions between transcription and translation regulation have had little systematic study, we cloned the FTL promoter 1400 bp upstream of the transcription start site (TSS), where a consensus, antioxidant response/Maf recognition element (ARE/MARE; 5'-TGACTCAGC-3') occurs at -1345 bp, into a luciferase reporter construct (FTL-LUC). Treatment of FTL-LUC transfected HepG2 cells with ARE/MARE inducers sulforaphane (2μM) and tert-Butylhydroquinone (TBHQ, 10 μM), or hemin induced FTL, thioredoxin reductase or quinone reductase (ARE/MARE containing promoters) similarly; protoporphyrin IX (80 μM) also induced FTL, comparably to hemin; FAC (ferric ammonium citrate) was a relatively poor regulator. ARE/MARE mutation eliminated responses to all inducers. To explore relationships between transcriptional and translational regulation, a chimeric reporter controlled by the FTL promoter plus the cognate mRNA iron responsive element (IRE) was constructed (FTL-LUC+IRE). FAC treatment increased FTL-LUC+IRE activity 2-3-fold, while hemin treatment increased activity 10-fold. ARE/MARE mutation decreased hemin induction to the level of FAC (~2-3-fold). These results demonstrate distinct responses of the ARE/MARE to oxidative stress and the IRE to iron stress and a synergistic induction by hemin which overlaps both regulation systems possibly through the known binding to repressor proteins Bach1 (ARE/MARE) and IRP1 or IRP2 (IRE). Support: NIDDK -20251.

**Small Fragment Homologous Replacement Modification (SFHR) of Genomic HPRT Occurs in the Presence of p53 in Lymphoblastoid Cells**

B. Bedayat,[1] A. Abdolmohammadi,[1,2] R. Maurisse,[1] J. Schwarz,[1] J. Cheung,[1] D. De Semir,[1] J. Patrick O'Neill,[3] J. A. Nicklas,[3] D. C. Gruenert[1,2,3]; [1]Research, California Pacific Medical Center, San Francisco, CA, [2]Department of Laboratory Medicine, University of California San Francisco, San Francisco, CA, [3]Department of Medicine, University of Vermont, Burlington, VT

Gene therapy has opened the door to new therapeutic interventions for the treatment of genetic diseases. In addition to the standard cDNA-based approaches, alternative gene targeting strategies have been developed. In this study, one of these gene targeting strategies, small fragment homologous replacement (SFHR), has been used to correct a point mutation in exon 3 of the hypoxanthine-guanine phosphoribosyltransferase (*HPRT*) gene . This point mutation inactivates HPRT gene and allows the cells to grow in 6-thioguanine (6TG) containing medium, but not in hypoxanthine/aminopterin/thymidine (HAT) containing medium. The lymphoblastoid cell line LT1-1B1 (p53+) was transfected with a 579-bp small DNA fragment (SDF) using the AMAXA Nucleofection/Electroporation system. Several different cell to SDF concentrations were examined. The efficiency of SFHR-mediated modification was assessed in p53+ cells to determine if the presence of p53 inhibited SFHR. Corrected cells were selected in HAT containing medium and further analyzed by PCR of the DNA and by reverse transcriptase PCR (RT-PCR) analysis of mRNA-derived cDNA. Quantitative analysis showed an SFHR correction frequency of up to $10^{-2}$.

**A Genome-wide Search for Candidate Genes Silenced by DNA Methylation in DNMT- Knockout HCT116 Cell Lines**

C. Sers,[1] R. Kuner,[2] A. Buness,[2] P. Lund,[1] M. Ruschhaupt,[2] B. Georffy,[1] A. Poustka,[2] H. Sueltmann,[2] R. Schaefer[1]; [1]Institute of Pathology, Charité, Berlin, Germany, [2]Molecular Genome Analysis, German Cancer Research Center, Heidelberg, Germany

The covalent modification of DNA by methylation is one of the best studied epigenetic mechanisms and results in silencing of gene expression. The overall genomic methylation is lower in cancer cells compared to normal cells. However, cancer cells exhibit hypermethylation of CpG-rich regions within the regulatory regions of distinct genes. DNA methyltransferases (DNMT´s) are considered to be responsible for the maintenance of DNA methylation patterns and for the de novo methylation during embryonic development and probably tumor progression. Genes which are concerned by changes in the global DNA methylation pattern could be identified by changes in the levels of transcribed RNA. In this study, we performed a genome-wide expression study of DNMT cellular models using cDNA-microarrays (37.5K). We compared the wildtype and 5-Aza-CdR treated KRAS-transformed colon carcinoma cell line HCT-116 versus specific knockouts of DNMT1, DNMT3B and double knockout (DKO) DNMT1/3B. We found 184 candidate genes upregulated in the DNMT1 and DNMT3B single knockouts. The strongest changes in gene expression (500 upregulated genes) were observed in the DNMT1/3B DKO. The statistical analysis of Gene Ontology classes resulted in biological processes like immune response and cell proliferation which are potentially inhibited in the cancer cell line by methylation and reactivated after inhibition of both DNA methytransferases. In comparison to DNMT1/3B DKO, the gene expression profile in 5-Aza-CdR treated cells was different. Here, many genes which are involved in more general processes like transcription, translation and replication were deregulated.

**Identifying Heterochromatin Initiators on *D Melanogaster* Chromosome Four**

G. A. Mensah, S. C. R. Elgin, K. Haynes; Biology, Washington University in St. Louis, St. Louis, MO

Heterochromatin is vital to the organization and regulation of a significant portion of the genome; thus understanding the mechanisms involved is essential to epigentics. In contrast to euchromatin, heterochromatin is more densely packaged, is enriched in repetitious sequences, and is located around the centromeres and at telomeres. Active genes that are normally found in euchromatin become silenced once they are translocated into or near heterochromatin, due to position effect variegation (PEV). Our investigation focuses on discovering which sequences trigger heterochromatin

formation. The distal portion of *Drosophila melanogaster* chromosome four (~1200 kb) contains interspersed euchromatic and heterochromatic domains. Previous mapping studies utilizing a mobile *P* construct carrying the PEV-sensitive *white* reporter gene indicate that fragments of repetitive *element 1360* are initiators of heterochromatin in a 200 kb region of the fourth chromosome (Sun et al., 2004). We believe there are additional heterochromatin initiators; not all heterochromatic domains of chromosome four contain *1360* elements. We carried out a *P* mobilization screen to identify other heterochromatin initiators starting with a *P* element in a euchromatic domain on the fourth, where flanking variegating domains lack the *1360* element. Once mobilized, we screened for cases where the *white* reporter shows a variegated eye phenotype, presumably due to a transposition, local genomic deletion or duplication that positioned it near heterochromatin. *P* duplications can also cause silencing of *white* (Dorer and Henikoff, 1994). We are using restriction mapping to identify lines with a single intact *P* element. Subsequently, we will use an inverse PCR (iPCR) based end-mapping technique to create a genetic map pinpointing novel nucleation sites for heterochromatin formation. Of 93 variegating lines recovered, approximately 42% have a duplicated *P*, indicating that this is a major mechanism for triggering heterochromatin formation. [Supported by NIH Grant GM068388]

### Silkworm EST Database and Its Application to Functional Studies

K. Mita,[1] M. Morimyo,[2] K. Okano,[3] Y. Koike,[4] J. Nohata,[1] K. Yamamoto,[1] S. Sasanuma,[1] M. Sasanuma,[1] H. Kawasaki,[5] M. G. Suzuki,[6] T. Shimada,[4] M. R. Goldsmith,[7] S. Maeda[6]; [1]Genome Research Group, National Institute of Agrobiological Sciences, Tsukuba, Japan, [2]National Institute of Radiological Sciences, Chiba, Japan, [3]Microbiology, Oregon State University, Corvallis, OR, [4]Agriculture and Environmental Biology, University of Tokyo, Tokyo, Japan, [5]Agriculture, Utsunomiya University, Utsunomiya, Japan, [6]Molecular Entomology, The Institute of Physical and Chemical Research (RIKEN), Wako, Japan, [7]Biological Sciences, University of Rhode Island, Kingstone, RI

We have sequenced more than 128,000 cDNA clones from 59 cDNA libraries that were constructed from various tissues and different developmental stages to date. All ESTs have been classified into more than 17,500 groups. The comparison with FlyBase suggests that the present EST database covers more than 80% of all the genes of *Bombyx mori*. About 35,000 EST among 128,000 ESTs are compiled into "KAIKObase" accessible at the website http://sgp.dna.affrc.go.jp. [EST microarray]: We synthesized 6,000 specific primers located about 500 bp downstream from the 5'end of each cDNA to remove repetitive sequences from DNAs to be used for the microarray. 6,000 DNAs were amplified by PCR with a T3 vector primer and a specific primer, followed by spotting on glass slides. [Lepidoptera-specific genes]: Comparative studies on gene sequences between Lepidoptera, *Drosophila*, *C. elegans* and other tissues for which genome analysis is well advanced can point to Lepidoptera-specific genes. Direct links of *KAIKObase* to *FlyBase* and *WormBase* provide ready identification of candidate Lepidoptera-specific genes. The genes coding for a chitinase, a sucrase, a glucose-1-phosphatase and a glycerophosphodiesterase are supposed to be candidates of horizontal gene transfer from bacteria to Lepidoptera.

### Age- and Cell Cycle-dependent Changes in EPC-1 Promoter Activity in Human Diploid Fibroblast-like Cells

K. Nakahama,[1] T. Kojima,[1,2] K. Yamamoto,[3] H. Uematsu,[2] I. Morita[1]; [1]Cellular Physiological Chemistry, Tokyo Medical and Dental University, Tokyo, Japan, [2]Department of Gerodontology, Tokyo Medical and Dental University, Tokyo, Japan, [3]Department of Biology, Tokyo Metropolitan Institute of Gerontology, Tokyo, Japan

OBJECTIVE; The changes in gene expression during senescence are very interesting. Early population doubling cDNA-1 (EPC-1) is one of the genes whose expression decreases dramatically during cellular aging. We examined the mechanism of EPC-1 expression during cellular ageing using human diploid lung fibroblast cells (TIG-3) in culture. METHODS; TIG-3 cells were cultured in minimum essential medium supplemented with 10% fetal bovine serum. The expression levels of EPC-1 mRNA and protein were measured by real-time PCR and western blotting respectively. The EPC-1 promoter activities were determined by the Dual-Luciferase Reporter Assay System. RESULTS; The EPC-1 mRNA level of TIG-3 cells at early population doubling level (PDL) was about 3-fold higher than that at late PDL. The change in the amount of EPC-1 protein secreted into the culture medium was similar to that observed for mRNA. In TIG-3 cells at late PDL, the EPC-1 promoter activity was not changed significantly by its promoter length. In contrast, TIG-3 cells at early PDL showed a marked increase in EPC-1 promoter activity when the length of the promoter was longer than 3200 bp. Furthermore, the promoter activity was dramatically decreased after serum stimulation in TIG cells at early PDL. Conclusions; We found the promoter/enhancer region of EPC-1 existed at more than 1761bp upstream from the transcriptional initiation site of the gene, and was regulated by both aging and cell cycle. These findings suggest that the age- and cell cycle-dependent expression of the EPC-1 gene is, at least in part, regulated transcriptionally. The further analysis of the promoter region of the EPC-1 gene will reveal the mechanism(s) of cellular ageing.

## Chromatin Remodeling (496-502)

496

### Chromatin Supraorganization and Extensibility in Mouse Hepatocytes with Aging

A. S. Moraes, M. L. S. Mello; Cell Biology, UNICAMP, Campinas, Brazil

The effects of aging on chromatin supraorganization and extensibility were studied in hepatocytes of liver imprints from 1-, 2-, and 15-week-old, and 1 through 2-year-old mice. Methods used involved topochemistry, image analysis, gravity action, and polarization microscopy. Nuclear areas and Feulgen-DNA amounts were found to increase with aging in agreement with the increase in the liver cell ploidy levels. Furthermore, young and old mice showed a slightly less packed chromatin (smaller average absorbance), but more heterogenously distributed chromatin condensation levels (higher entropy), in relation to adult mice. Con-A reactive nuclear matrix glycoproteins also increased in old mice, while they were almost absent in young mice. A lysis treatment to fixed preparations induced an increased frequency of extended chromatin fiber (ECF) formation following aging. Previous works on accessibility of chromatin to nucleases described an increase in chromatin packing states in nuclei from old mice; a decrease in gene activity was also reported. The mentioned changes following aging could be a function of defects in the heterochromatin formation due to the loss of telomeres with this process, thus explaining the higher ECF formation and chromatin unpackaging in old mice. In young mice, a less packed chromatin state could probably be correlated with a more intense gene activity. Because of that, more points of

interaction between the chromatin and nuclear matrix would appear, thus inhibiting ECF formation, in spite of the less packed chromatin. The differences in content of Con-A responsive nuclear matrix glycoproteins are assumed to be related to different degrees of gene activity with advancing development and aging. (Supported by CNPq/Brazil)

**Cabin1 Represses MEF2 Transcriptional Activity by Association with Methyltransferase, SUV39H1**

H. Jang, H. Youn; Seoul Nat'l Univ. College of Medicine, Seoul, Republic of Korea

Cabin1, a calcineurin binding protein, was known as a transcriptional repressor of MEF2, which can be released from MEF2 in a calcium-dependent fashion. So far, the molecular basis of repression of MEF2 by Cabin1 was identified as two distinct mechanisms. Cabin1 recruits mSin3 and its associated histone deacetylases 1 and 2; Cabin1 also competes with p300 for binding to MEF2. Besides these two mechanisms, we report that Cabin1 represses MEF2 transcriptional activity by recruiting SUV39H1. First, we found that immunoprecipitated Cabin1 complex methylated Histone H3. And among histone methyltransferases, SUV39H1 associated with Cabin1 *in vivo* and *in vitro*. The SUV39H1 binding domain of Cabin1 was found to the amino acid 501-900 region. Second, SUV39H1 repressed MEF2 transcriptional activity on the Nur77 Promoter. The amino acid 501-900 region of Cabin1, which cannot recruit mSin3 and its associated histone deacetylases, also repressed transcriptional activity. Thus, Cabin1 recruits SUV39H1 and uses its histone methyltransferase activity to repress MEF2 transcriptional activity.

**DLAD Activity in Differentiating Lens Fiber Cells**

A. B. De Maria,[1,2] S. Bassnett[1]; [1]Ophthalmology, Washington University, St Louis, MO, [2]Biologia Celular y Molecular, Facultad de Ciencias, Universidad de la Republica, Montevideo, Uruguay

Eye lens transparency is achieved, in part, by elimination of intracellular organelles from fiber cells located in the center of the tissue. Mitochondria, endoplasmic reticulum and Golgi disappear synchronously, leading to the formation of an organelle-free zone. At the edge of this zone, nuclear breakdown involves loss of the lamina and envelope and, ultimately, chromatin degradation. Several nuclease activities have been detected in lens extracts, but only one, DLAD (DNase II-like acid DNase), has been shown unequivocally to play an active role in chromatin degradation. To better define the role of DLAD in fiber cell DNA degradation, we examined DNA fragmentation in wild type and DLAD knockout mice lenses. To visualize the DLAD expression pattern in the lens we developed an imprinting activity assay in which nuclease diffusing from a tissue slice digests an immobilized DNA substrate. The assay indicated that DLAD activity was present throughout the fiber bulk and enriched in the superficial fibers with intact nuclei. DLAD-mediated scission is believed to generate DNA free 3'-$PO_4$ ends. To detect fragmented DNA, lens tissue was TUNEL labeled with and without alkaline phosphatase (CIAP) pretreatment. In wild type lenses, TUNEL label was detected in nuclear remnants, indicating the presence of 3'-OH ends in the degraded DNA. Significantly, the amount of TUNEL labeling was not increased with CIAP treatment, suggesting that 3'-$PO_4$ ends do not accumulate. In DLAD null mice, fiber cell nuclei were not TUNEL positive, hence, DLAD may be the only nuclease responsible for chromatin degradation during nuclear breakdown. The absence of detectable 3'-$PO_4$ termini may be explained by the activity of an endogenous phosphatase that rapidly eliminates the $PO_4$ groups.

499

**Global Role of the Swi/Snf Chromatin Remodeling Complex in the Transcriptional Regulation of Glucocorticoid Receptor-Dependent Genes**

S. John,[1] T. A. Johnson,[1] C. Elbi,[1] D. A. Walker,[1] P. Meltzer,[2] A. Imbalzano,[3] G. L. Hager[1]; [1]Lab of Receptor Biol and Gene Expression, Natl Cancer Inst, Bethesda, MD, [2]Cancer Genetics Branch, NHGRI, Bethesda, MD, [3]Dept of Cell Biol, Univ of Massachusetts Med Sch, Worcester, MA

Brahma (Brm) and Brahma-related gene 1 (Brg1) serve as the ATP-dependent catalytic subunits of the swi/snf family of chromatin remodeling complexes. These complexes disrupt histone-DNA interactions and thereby provide a mechanism by which transcription factors can overcome the stearic hindrance imposed by nucleosomes. Using the well studied steroid responsive mouse mammary tumor virus promoter (MMTV), we show that both Brg1 and Brm can function on the same promoter. In Brg1 and Brm null cell lines, we find that both remodelers can potentiate the hormone-dependent response of the MMTV promoter. Immunofluorescence microscopy in cell lines with an array containing tandem repeats of the MMTV promoter show that endogenous Brg1 and Brm rapidly associate with the promoter in a dexamethasone-dependent fashion. Both biochemical and imaging approaches demonstrate that MMTV transcription is significantly reduced in cells that express catalytically inactive, dominant negative forms of Brg1 and Brm. We assessed the contribution of chromatin remodeling complexes on global gene expression by microarray analysis and found that a significant number of glucocorticoid receptor regulated genes require Brg1 for an optimal transcriptional response. This underscores a global role for Brg1 in nuclear receptor function. *In vivo* photobleaching experiments of Brg1 and Brm on the MMTV promoter demonstrated that chromatin remodeling complexes possess different kinetic properties correlating with their functional effect on MMTV transcription. Quantitative DNA fluorescence in situ hybridization experiments showed that a hormone-dependent decondensation of the MMTV array serves as an indicator of the transcriptional response and inactive Brg1 can prevent the hormone-dependent decondensation of MMTV chromatin. Thus our data indicate that MMTV transcription is regulated dynamically by multiple members of the swi/snf family of chromatin remodelers and the transcriptional response is reflected by chromatin remodeling.

**SWI/SNF Complex and Histone Acetylation Cooperate with STAT5 And C/EBPβ to Regulate β-casein Transcription**

R. Xu, V. A. Spencer, M. J. Bissell; Life Science Division, Lawrence Berkeley National Laboratory, Berkeley,, CA

In culture, treatment with lactogenic hormones and ECM molecules induces differentiation of mammary epithelial cells (MECs), exemplified by expression of milk proteins and formation of tissue-like structures. The gene encoding the milk protein beta-casein has been used widely as a marker for functional differentiation of MECs. Expression of the beta-casein gene is regulated by both extracellular cues and transcription factors, but how these signals lead to chromatin remodeling is not understood. Using chromatin immunoprecipitation (ChIP) assays, we now show that extracellular matrix (ECM) and prolactin cooperate to induce binding of transcription factors and SWI/SNF complex, as well as histone acetylation

in the beta-casein promoter. However, enhancing histone acetylation by treatment with a histone deacetylase inhibitor was not sufficient to induce expression of the endogenous gene. Introduction of an ATPase-deficient SWI/SNF complex significantly reduced beta-casein expression, suggesting that SWI/SNF-dependent chromatin remodeling is required for transcription. Co-immunoprecipitation analyses showed that the SWI/SNF complex is associated with STAT5, C/EBP beta, and glucocorticoid receptor (GR). These observations indicate that the functional differentiation of mammary epithelial cells requires the concerted action of both transcription and chromatin remodeling factors.

**Translocation Mechanism of Chromatin Remodeling Revealed by Single-molecule Studies**

Y. Zhang,[1] C. L. Smith,[2] A. Saha,[3] S. W. Grill,[1] S. B. Smith,[4] B. R. Cairns,[3] C. L. Peterson,[2] C. Bustamante[4]; [1]Department of Molecular and Cell Biology, University of Carlifornia, Berkeley, CA, [2]Program in Molecular Medicine, University of Massachusetts Medical School, Worcester, MA, [3]Department of Oncological Sciences, Huntsman Cancer Institute and Howard Hughes Medical Institute, University of Utah School of Medicine, Salt Lake City, UT, [4]Department of Physics, Department of Molecular and Cell Biology, Department of Chemistry, and HHMI, University of Carlifornia, Berkeley, Berkeley, CA

ATP-dependent chromatin remodeling complexes are a large family of molecular motors that facilitate protein binding to nucleosomal DNA, transfer histone octamers in *cis* or *trans*, assemble chromatin, or exchange histones. Despite their diverse functions, these remodeling complexes share highly conserved ATPase domains and are capable of altering nucleosomal DNA configuration. However, the molecular nature of this modification and the molecular mechanisms by which it is generated remain poorly understood. Here we observe the real-time activity of two remodelers, ySWI/SNF and RSC, on single, stretched nucleosomal array templates. We show that the remodelers bind to nucleosomes and translocate DNA to form large DNA loops. Both remodelers have similar kinetic profiles and translocate at an average velocity of ~ 14 bp/s and a processivity of ~ 100 bp. Although translocation has to initiate below 7 pN of DNA tension, the remodelers can continue reeling DNA against a force up to ~ 12 pN. A DNA loop so generated either dissipates suddenly or reduces its size continuously by what appears to be a reverse translocation. Our data suggest a model for how remodelers use DNA translocation to catalyze nucleosome movements and configurational transitions.

502

***Clockswitch* is an ATP-Dependent Chromatin Remodeling Enzyme Required for Normal Circadian Regulation of the *frequency* Gene in *Neurospora crassa***

W. J. Belden, J. J. Loros, J. C. Dunlap; Genetics Department, Dartmouth Medical School, Hanover, NH

Circadian rhythms in eukaryotic organisms are established by positive and negative transcriptional/translation feedback loops. The filamentous fungus, *Neurospora crassa* contains a model circadian feedback loop that is controlled by daily oscillations in transcription of the *frequency* gene. The PAS domain containing transcription factors White Collar-1 (WC-1) and White Collar-2 (WC-2) form the White Collar Complex (WCC) that positively regulates *frq* expression in a circadian and light dependent manner. Although much is known about the transcriptional regulation of core clock components in *Neurospora*, nothing is known about how nucleosome modifications and chromatin remodeling function in regulating transcription. We demonstrate through chromatin immunoprecipitations that WC-2 binds to the *frq* promoter in a rhythmic fashion whereas WC-1 is continuously bound. We do not detect oscillations in histone H3 acetylation (H3Ac) however there is a drastic reduction in the level of H3Ac upon light induction. Nuclease accessibility experiments suggest that chromatin in the *frq* promoter changes when the gene is expressed. In order to identify the chromatin remodeling enzyme that regulates clock gene expression, a systematic deletion analysis of annotated remodeling factors was performed. We identified a single gene out of 19 annotated DNA remodeling factors that affects clock function. This gene, now designated *clockswitch* (*csw-1)* affects the transcription of *frq* as well as other genes regulated by the WCC. Antibodies generated against the N-terminal variable region indicate that CSW-1 is localized to the Clock activating activating sequence in the *frq* promoter. We also detect CSW-1 dependent chromatin remodeling at the C-box promoter element using limited MNaseI digestion followed by indirect endlabeling. These data demonstrate that chromatin remodeling is necessary for circadianly regulated gene expression.

## Nuclear Matrix and Nuclear Architecture (503-512)

503

**Nuclear Membrane, Chromatin and Nucleoli: A study of Spatial Relations in the *Didinium nasutum* Macronucleus by Means of Stereoreconstruction**

B. P. Karajan,[1] O. G. Leonova,[2] Y. F. Ivlev,[3] J. L. Ivanova,[2] V. I. Popenko[2]; [1]Institute of Cytology Russian Academy of Sciences, Saint Petersburg, Russian Federation, [2]Engelhardt Institute of Molecular Biology Russian Academy of Sciences, Moscow, Russian Federation, [3]Severtsov Institute of Ecology and Evolution Problems Russian Academy of Sciences, Moscow, Russian Federation

A positional relationship of nuclear membrane elements, chromatin and nucleoli in the somatic nucleus of *Didinium nasutum* cyst was studied by stereoreconstruction on the basis of serial ultrathin sections. Mean concentration of nuclear pores at this stage was ~50 pores per $mkm^2$ , i.e. two times lower than at the interphase. Nuclear pores were situated on the membrane non-uniformly, but we did not succeeded in finding a correlation between location of chromatin structures and nucleoli near the nuclear membrane and nuclear pores concentration. At the cyst stage macronuclear chromatin was shown to be represented by a few individual chromatin clumps and, mainly, by fibrils of variable (100-300 nm) thickness and up to 2000 nm in length. The data obtained show that the approach combining electron microscopy, ultrathin sectioning and computer modelling allows one to build up 3D models of large areas of a cell nucleus at ~50 nm resolution and, therefore, it can be used for creation the computer models of cell nucleus functioning.

504

**Recruitment of Nup37 And Nup43 to Kinetochores: Biochemical Analyses and High Resolution Real-Time Visualisation**

S. P. Drummond, T. D. Allen; Structural Cell Biology, Paterson Institute for Cancer Research, Manchester, United Kingdom

Nuclear pore complexes (NPCs) are the gateways for both active and passive bi-directional molecular transport between the nucleoplasm and

cytoplasm during interphase. These mega-dalton assemblies are composed of multiple copies of approximately 30 distinct proteins termed nucleoporins (nups). During mitosis, in higher eukaryotes, NPCs disassemble and become dispersed throughout the cell, either as a diffuse cytoplasmic pool or are targeted to discrete sub-structures. Several nucleoporins, and presumably the nups they remain bound to during mitosis, are re-distributed to kinetochores until they are recruited back to the periphery of chromatin as NPCs are re-assembled. We have used real-time high resolution confocal microscopy to track GFP-tagged nup37 and nup43 in mammalian cells and directly observe the dynamics of these proteins throughout the cell cycle. In addition immuno-gold scanning electron microscopy (SEM) revealed the exact location of these nups during mitosis with respect to previously characterized kinetochore components. In order to investigate the requirements for nup37 and nup43 localisation to kinetochores, pSUPER constructs were used to down-regulate proteins located to kinetochore boundaries and the effects of such biochemical manipulations were again assayed using SEM and real-time deconvolution confocal microscopy.

505

### *In vitro* Assembly of Nuclear Lamins

N. Foeger,[1] N. Mucke,[2] N. Wiesel,[3] Y. Gruenbaum,[3] U. Aebi,[4] H. Herrmann[1]; [1]Department of Molecular Genetics, German Cancer Research Center, Heidelberg, Germany, [2]Department of Biophysics of Macromolecules, German Cancer Research Center, Heidelberg, Germany, [3]Department of Genetics, Hebrew University, Jerusalem, Israel, [4]M.E.Mueller Institute for Structural Biology, Biocenter, Basel, Switzerland

The nuclear lamins (NL) are nucleus-specific intermediate filament proteins that together with a complex set of membrane proteins form a filamentous meshwork tightly adhering to the inner nuclear membrane. This so-called nuclear lamina provides mechanical stability and, in addition, has been implicated in the organization of interphase chromosomes. In contrast, relatively little is known about the assembly mechanism of NLs and the specific properties of NL polymers at the molecular level. Therefore, we have more systematically investigated NL assembly *in vitro*. In particular, we identified and characterized distinct intermediates in the NL filament assembly process by negative staining and glycerol spraying/rotary metal shadowing electron microscopy. Moreover, we investigated the different assembly intermediates by analytical ultracentrifugation. Using *Caenorhabditis elegans* lamin, which has been reported to assemble into 10-nm filaments under low ionic strength conditions (Karabinos *et al*, J.Mol.Biol. (2003) **325**, 241-247), we investigated the assembly kinetics of this NL protein into filaments in more detail. Contrary to present views, we found that NLs may assemble very rapidly into large filament networks. In parallel, we investigated human recombinant lamins A/C, B1 and B2 in our *in vitro* assay system with respect to different filament assembly conditions. Last but not least, the influence of lamin-interacting proteins such as LAP2 on the assembly was explored.

### The Ultrastructure of Cytoplasmic Bodies formed by a Mutant Promyelocytic Leukemia Protein

D. Dinsdale,[1] C. Bellodi,[1,2] T. Smith,[1] J. McWilliam,[1] K. Kindle,[3] F. Bernassola,[4] A. Cossarizza,[2] G. Melino,[1] D. Heery,[3] P. Salomoni[1]; [1]MRC Toxicology Unit, Leicester, United Kingdom, [2]Department of Biomedical Sciences, University of Modena and Reggio Emilia, Modena, Italy, [3]School of Pharmacy, University of Nottingham, Nottingham, United Kingdom, [4]IDI-IRCCS Biochemistry Laboratory, c/o Department of Experimental Medicine, University of Rome, Tor Vergata, Rome, Italy

The tumor suppressor promyelocytic leukemia (PML) protein characterizes the eponymous nuclear bodies of normal cells but mutant forms, associated with acute promyelocytic leukemia (APL), lack the p53 interaction domain and thus the allied pro-apoptotic and growth-suppressive functions. These mutants also lack the nuclear localization signal, suggesting that they localize to the cytoplasm in APL cells. Furthermore, endogenous PML cytoplasmic isoforms have been identified, although their relationship with PML mutant forms is still unclear. Anti-PML antibodies enabled the localization of endogenous nuclear and cytoplasmic PML bodies in both normal and transformed human fibroblasts but the ultrastructure of these bodies was compromised by the mild fixation conditions required to preserve antigenicity. Primary cells were infected with retroviral supernatants from pBABE-HA-Mut1 transfected packaging cells. Antigenicity for both PML and the HA tag was detected in nuclear PML bodies of infected cells and many also exhibited double-labeled cytoplasmic PML bodies. The HA-epitope proved to be much less sensitive to fixation than PML and so samples could be prepared to retain fine cellular detail, particularly the endomembranes. The resulting samples established that the cytoplasmic PML bodies were devoid of a limiting membrane and independent of mitochondria, lysosomes and the endoplasmic reticulum. This finding was unexpected, as an association with early endosomes has been reported in some murine cells, possibly reflecting a particular stage of development or the difference in species.

### Knockout of Cajal Body Marker Protein Coilin Results in Decreased Transcription Efficiency

H. Xu, M. D. Hebert; Biochemistry, University of Mississippi, Medical Center, Jackson, MS

The eukaryotic cell nucleus is organized into different non-membrane bound nuclear subdomains. One of these subdomains, the Cajal body (CB), contains a host of RNA transcription and processing factors including RNA polymerase II subunits, spliceosomal ribonucleoproteins, Survival of Motor Neuron protein (SMN), and fibrillarin. As such, it is likely that this structure plays an indirect role in both RNA transcription and splicing. The marker protein for the CB, coilin, is important for CB formation and composition; coilin knockout mice demonstrate viability and proliferation problems. Embryonic fibroblasts derived from coilin knockout mice do not have canonical CBs. In contrast, two types of residual CBs, each containing a partial repertoire of CB components, are found in coilin knockout cells (Tucker et al. 2001; Jady et al. 2003). To explore CB function, we further characterized the coilin knockout cells. We found that coilin knockout cells have a significantly slower growth rate compared to wild type cells with normal CBs, consistent with a role of CBs in some aspect of transcription control or RNA processing. When challenged with exogenous RNA transcription and splicing substrates, the knockout cells demonstrate notably lower transcription efficiency as shown by RT-PCR and RNase Protection Assays, with no appreciable deficiency in pre-mRNA splicing compared to wild type cells. Thus canonical CBs, organized by coilin, appear to be critical in maintaining transcription efficiency. In order to confirm the result, we are investigating the transcription level of endogenous housekeeping gene in both wild type and coilin knockout cells.

508

**Convergence of DDX1 Foci, Cleavage Bodies, Cajal Bodies and Gems During the S Phase of the Cell Cycle**

L. Li, K. Roy, X. Sun, R. Godbout; Oncology, University of Alberta, Edmonton, AB, Canada

DDX1 foci, cleavage bodies, Cajal bodies (CBs) and gems are nuclear bodies postulated to be involved in RNA transcription, splicing and processing, perhaps by serving as pre-assembly sites for factors involved in these processes. Although all four nuclear bodies are distinct entities, they have been shown to either co-localize or partially overlap with each other. To better understand the relationship between these four nuclear bodies, we have used a three-dimensional image reconstruction program to examine the spatial distribution of DDX1 foci, cleavage bodies, CBs and gems as a function of the cell cycle. Here, we report that while DDX1 foci, CBs and gems are present throughout G1, S and G2 phases of the cell cycle, cleavage bodies are predominantly found during S phase in both HeLa and GM38 normal fibroblasts. All four nuclear bodies associate with each other during S phase, with cleavage bodies co-localizing with DDX1 foci, and cleavage bodies/DDX1 foci residing adjacent to gems and CBs. While inhibitors of RNA transcription had no effect on DDX1 foci or cleavage bodies, a dramatic alteration in the structure of cleavage bodies was observed in the presence of latrunculin B, an inhibitor of actin polymerization, suggesting a role for nuclear actin or an actin-related protein in the assembly of cleavage bodies and/or their correct positioning within the nucleus.

509

**Sp2 Localizes to Stable, Sub-Nuclear Foci Associated with the Nuclear Matrix**

K. S. Moorefield,[1] T. D. Nichols,[1] C. Cathcart,[2] S. O. Simmons,[1] J. M. Horowitz[1]; [1]Molecular Biomedical Sciences, North Carolina State University, Raleigh, NC, [2]Nikon Instruments, Inc., Melville, NY

Sp/XKLF proteins comprise a large family of sequence-specific DNA-binding proteins that share a highly conserved, carboxy-terminal DNA-binding domain. Sp2 is ubiquitously expressed and carries the least conserved DNA-binding domain amongst Sp-family members. We have reported that Sp2 binds poorly to a subset of DNA sequences bound by other family members, and has little or no capacity to stimulate transcription of promoters that are potently activated by Sp1, Sp3, and Sp4. Using an array of chimeric Sp1/Sp2 proteins, we showed further that Sp2 DNA-binding activity and *trans*-activation are each negatively regulated in mammalian cells. As part of an ongoing effort to study Sp2 function and regulation we characterized its subcellular localization in comparison with other Sp-family members in fixed and live cells. We report that Sp2 is localized largely within sub-nuclear foci, distinct from promyelocytic (PML) oncogenic domains (PODs), which are associated with the nuclear matrix. Using time-lapse confocal microscopy we report that Sp2 foci appear to be stable and virtually immobile during an 18 hour time course of observation. We also report that (1) Sp3 is distributed diffusely throughout the nucleus and only a minority of Sp3 or Sp4 is associated with the nuclear matrix, and (2) the association of Sp1 with the nuclear matrix appears to be somewhat less frequent than that of Sp2. Using a panel of partial EYFP-Sp2 fusion proteins we identified a 31 amino acid portion of the Sp2 DNA-binding domain as being necessary to direct nuclear matrix association. This portion of the Sp2 DNA-binding domain is the most divergent amongst Sp-family members. We conclude from these studies that Sp2 preferentially associates with the nuclear matrix and speculate that this association may play an important role in the regulation of Sp2-mediated transcription.

510

**Nuclear Speckles and Nucleoli Targeting by $PIP_2$-PDZ Domain Interactions**

E. Mortier,[1] G. Wuytens,[1] I. Leenaerts,[1] F. Hannes,[1] M. Y. Heung,[2] G. Degeest,[1] G. David,[1] P. L. Zimmermann[1]; [1]CME, Kuleuven, Leuven, Belgium, [2]Department of Biosciences, University of Birmingham, Birmingham, United Kingdom

PDZ domains are protein-protein interaction modules that predominate in submembranous scaffolding proteins. Recently, we showed that the PDZ domains of syntenin-1 also interact with phosphatidylinositol 4,5-bisphosphate ($PIP_2$) and that this interaction controls the recruitment of the protein to the plasma membrane. Here we evaluate the general importance of $PIP_2$-PDZ domain interactions. We report that most PDZ proteins bind weakly to $PIP_2$, but that syntenin-2, the closest homolog of syntenin-1, binds with high affinity to $PIP_2$ via its PDZ domains. Surprisingly, these domains target syntenin-2 to nuclear $PIP_2$ pools, in nuclear speckles and nucleoli. Targeting to these sites is abolished by treatments known to affect these $PIP_2$ pools. Mutational and domain swapping experiments indicate that high-affinity binding to $PIP_2$ requires both PDZ domains of syntenin-2, but that its first PDZ domain contains the nuclear $PIP_2$ targeting determinants. Depletion of syntenin-2 disrupts the nuclear speckles-$PIP_2$ pattern and affects cell survival and cell division. These findings show that $PIP_2$-PDZ domain interactions can directly contribute to subnuclear assembly processes.

**Testing the Role of NuMA in Structuring the Interphase Nucleus**

A. D. Silk, P. S. Maddox, D. R. Foltz, A. Desai, D. W. Cleveland; CMM, UCSD, La Jolla, CA

It is well established that the nucleus is an architecturally complex organelle, in which chromosomes are thought to inhabit defined territories and many nuclear proteins are arranged into discrete sub-compartments. While characterization of the highly organized nature of the nucleus is well underway, few data exist which address the basic question of how, or even the degree to which the nucleoplasm is structured. A good candidate for a structural protein within the nucleus is the Nuclear Mitotic Apparatus protein (NuMA). To test a possible nuclear function for NuMA, a conditional knockout approach has been taken to generate mice that contain an allele of NuMA in which the nuclear localization sequence (NLS) is removable by Cre recombinase action. Additionally cell lines have been established that express an siRNA resistant, NLS deficient NuMA variant that complement mitotic deficits caused by knockdown of the endogenous protein, and allow an investigation into NuMA's nuclear role. Further, to analyze the function of NuMA in nuclear structure, an *in vitro* assay has been developed using spinning disc confocal microscopy. This assay is based on the property of higher order chromatin to undergo reversible restructuring in response to variation in $Mg^{2+}$ concentration. Quantitative analysis of two-color images allows simultaneous spatial and temporal resolution of changes in the distribution of chromatin (marked by fluorescently labeled histones) and nuclear sub-domain proteins. Using this assay, we found that the behavior of NPM1 (nucleophosmin, a nucleolar protein) parallels that of chromatin, while ASF/SF2 (a splicing speckle component) does not. Use of this assay, combined with siRNA-mediated removal of nuclear NuMA will determine how the removal of nuclear NuMA affects interphase chromatin distribution and the chromatin-dependent organization of multiple nuclear sub-domains.

512

### The *in situ* Response of Subnuclear Domains to Mechanical Forces Applied at the Nuclear Envelope

J. Pajerowski,[1] K. N. Dahl,[2] D. E. Discher[3]; [1]Bioengineering, University of Pennsylvania, Philadelphia, PA, [2]Cell Biology, Johns Hopkins, Baltimore, MD, [3]Cellular and Biomolecular Engineering, University of Pennsylvania, Philadelphia, PA

Nuclear plasticity, DNA bending, and related mechanical descriptors are commonly applied to the nucleus and its sub-structures, but there are few if any direct measures on cells. TC7 monkey kidney epithelial cells have been transfected with GFP Lamin A and B23, markers for the nuclear lamins and nucleolus. Micropippete aspiration of intact, suspended cells was conducted. Analysis of deformation yields information about the viscoelastic properties of the intact nucleus, as well as the nucleoli. Nucleolar deformation begins to suggest how forces are transmitted through the nucleus to subnuclear compartments. The non-homogeneous nature of intranuclear material is apparent. Nucleolar tethering events can be observed, as well as the existence of chromatin domains that exhibit varying levels of connectedness. Paralleling previous work in isolated nuclei, the creep compliance of *in situ* nuclei can be fit to a power law. In contrast to isolated nuclei, in situ nuclei exhibit a crossover from an initial power law to a more shallow power law at around 10 seconds. The second power law is similar to that displayed by swollen isolated nuclei. In order to further validate the in situ micropipette assay, cells were exposed to various treatments expected to have an effect on the physical state of the chromatin. Elevated intracellular calcium levels, induced by either selective permeabilization to divalent cations using ionophore A23187, or nonselective permeabilization using digitonin, caused a measurable increase in the stiffness of the nuclei as measured by their creep compliance. This work demonstrates that the technique of micropipette aspiration can be used to probe the structure of the *in situ* nucleus, as well as sub nuclear deformation.

### Characterization of Allurin-Mediated Sperm Chemotaxis in *Xenopus laevis*

L. Burnett, A. Holburn, A. Bieber, D. Chandler; Arizona State University, Tempe, AZ

Allurin, a *X. laevis* sperm chemoattractant, was previously identified, purified, and characterized in our laboratory; however, the mechanics of allurin-sperm interaction leading to chemotaxis remain undetermined. Here we demonstrate allurin-sperm binding and preliminary studies for isolation and characterization of the allurin receptor on *Xenopus* sperm. Allurin binding studies were performed using both allurin conjugated with a fluorescent tracking dye and a crosslinking reagent that stabilizes the allurin-receptor complex. Oregon-Green 488 conjugated allurin, used to label sperm before, during and after activation of motility created a specific staining pattern that demonstrated the location of the allurin receptors on sperm. Furthermore, photo-crosslinking of allurin to its receptor was achieved and allowed primary separation of the receptor complex from total cell proteins. Preliminary data points to a glycosylated receptor complex greater than 150 kD molecular weight. In addition, we have begun to examine the role of specific secondary messengers in allurin-mediated sperm chemotaxis. Calcium is involved in chemotaxis in both invertebrates and mammals; we therefore began investigating what role it may play in allurin-mediated chemotaxis in two ways: fluorescent labeling with Calcium Green and disruption of calcium signaling using the ionophore ionomycin. Here we also report that disruption of calcium signaling by ionomycin results in a reduction of the ability of *Xenopus* sperm to undergo chemotaxis. This study of allurin binding and calcium signaling in sperm will lead to a model of the mechanisms and signal transduction pathways involved in sperm chemotaxis. This study was supported by NSF grant IBN-0130001.

### SK Channel Regulation of the Fertilization $Ca^{2+}$ Signal in Sea Urchin Eggs

C. D. Thaler,[1] C. Patton,[1] J. Maylie,[2] D. Epel[1]; [1]Stanford University, Hopkins Marine Station, Pacific Grove, CA, [2]Obstetrics and Gynecology, Oregon Health & Science University, Portland, OR

Egg activation at fertilization requires an acute rise in intracellular $Ca^{2+}$. In sea urchin eggs, $Ca^{2+}$ influx through voltage gated $Ca^{2+}$ channels and release from internal stores mediated by IP3 and/or ryanodine receptors contribute to fertilization induced $Ca^{2+}$ release. Studies with isolated microsomes suggest that an apamin-sensitive small conductance $K^+$ (SK) channel, activated by submicromolar $Ca^{2+}$, is required for optimal $Ca^{2+}$ release (Biochem J. 300:673-83). SK channel activation will potentiate $Ca^{2+}$ release by increasing the electrochemical driving force for $Ca^{2+}$ (Nature 395:908-912). To examine the potential role of an SK channel during fertilization of sea urchin eggs, the effect of microinjected SK channel blockers on the fertilization $Ca^{2+}$ signal was examined. Injection of tetrabutylamonium, TBuA, a non-selective $K^+$ channel blocker reduced the duration of the $Ca^{2+}$ wave with a dose-response similar to that for intracellular block of cloned SK channels. TBuA (~10 mM) reduced the half-width of the $Ca^{2+}$ signal from 153±3 s (n=9) to 25±1 s (n=16) and decreased the peak by 11±4%. Injection of the selective SK channel blocker, apamin, similarly reduced the duration of the $Ca^{2+}$ wave in ~1/2 of the eggs injected, consistent with restricted access to the SK channel apamin binding site which is presumably located within the ER lumen. Bath application of apamin did not affect the $Ca^{2+}$ signal suggesting that the apamin response is specific for release of $Ca^{2+}$ from intracellular stores. Similarly, block of surface membrane voltage gated $Ca^{2+}$ channels suppressed the initial $Ca^{2+}$ flash but did not affect the response to TBuA injection. These data suggest that an SK channel localized to intracellular $Ca^{2+}$ stores is activated by intracellular $Ca^{2+}$ and exerts a hyperpolarizing influence on the internal stores' membrane potential to maintain a driving force for $Ca^{2+}$ release.

515

### The Role of Phosphatidic Acid in Regulation of Intracellular Calcium during Fertilization in *Xenopus*

B. J. Stith,[1] J. Stafford,[1] Y. Chang,[1] T. Kane,[2] R. Bates,[2] A. Nickle,[2] D. Petcoff[2]; [1]Biology, University of Colorado Denver, Denver, CO, [2]Biology, Metropolitan State College, Denver, CO

The current model for fertilization in *Xenopus laevis* is that sperm somehow activates Src tyrosine kinase and that this enzyme activates phospholipase Cgamma (PLCgamma). Activation of PLC is central to fertilization as it leads to increased inositol 4,5-bisphosphate (IP3). IP3 binds an intracellular receptor to release intracellular calcium and induce subsequent fertilization events. Through Western blotting and RT-PCR that show only one isoform of PLD, we suggest that sperm activate phospholipase D1b to elevate phosphatidic acid (PA), and that PA then activates Src

tyrosine kinase which activates PLC during *Xenopus* fertilization. PA increased during *Xenopus* fertilization (from ~1 to 2.8 ng per cell; peaked at ~1 min) and that prevention of this increase inhibited fertilization. Addition of PA to eggs released intracellular calcium, and this release was inhibited by an IP3 receptor blocker (PLC inhibitor U73122 also inhibited calcium release in a plasma membrane preparation; U73343 was inactive). PA also increased IP3 mass in the absence of elevated intracellular calcium. PA or sperm addition to *Xenopus* eggs activated *Xenopus* Src (as measured by a phosphospecific ELISA kit for tyrosine 418 phosphorylation from BioSource, Inc.; PS was ineffective). As six different tyrosine kinase inhibitors reduced IP3 production or calcium release by PA (~50%), PA may activate PLC in part through activation of Src. Using Western blotting with a phosphospecific PLCgamma antibody, addition of PA to eggs not only stimulated Src activity but also increased activating tyrosine phosphorylation of PLCgamma.

**Where Does Extracellular Calcium Act in the Bicarbonate-Signaled Activation of Mouse Sperm?**

A. E. Carlson, B. Hille, D. F. Babcock; Physiology and Biophysics, University of Washington, Seattle, WA

The maturation of mammalian sperm within the female reproductive tract begins with an early activation of rapid motility that is produced by an increased flagellar beat frequency. The bicarbonate anion is the probable physiologic activator of this increase in motility, acting directly to stimulate the atypical adenylyl cyclase of sperm and engage cAMP-dependent protein kinase to phosphorylate components of the flagellum. Previously, we found that extracellular $Ca^{2+}$ is required for bicarbonate to increase and maintain an elevated flagellar beat frequency of epididymal mouse sperm. Here we have asked where extracellular $Ca^{2+}$ acts in this bicarbonate-signaling path. Using ratiometric photometry with the $Ca^{2+}$ sensitive indicators fura-2 or FFP18, we monitored intracellular [$Ca^{2+}$] in small groups of sperm during stimulus by perfusion with 15 mM $NaHCO_3$. Bicarbonate did not increase either cytosolic or near-membrane [$Ca^{2+}$], indicating that bicarbonate action does not produce a required entry of $Ca^{2+}$. When external $Ca^{2+}$ was removed before and during treatment with bicarbonate, intracellular [$Ca^{2+}$] decreased only slowly over several tens-of-seconds. However, the actions of bicarbonate to increase cAMP content and the flagellar beat were blocked completely within a few seconds after removal of external $Ca^{2+}$, suggesting that bicarbonate does not require a critical threshold intracellular [$Ca^{2+}$]. The most likely remaining explanation is that external $Ca^{2+}$ has a required role in the entry of the bicarbonate anion into the sperm. *Support from U54-HD12629 of the SCCPR program of NICHD. A.E.C. supported in part by NRSA T32 GM07270 from NIGMS.*

**Hyperactivated Motility of Sperm is Regulated by pH-Sensitive $Ca^{2+}$ Channels**

B. Marquez, S. S. Suarez; Biomedical Sciences, Cornell University, Ithaca, NY

Sperm hyperactivated motility consists of high flagellar bend amplitude and asymmetrical beating that is required for sperm penetration of the oocyte zona pellucida during fertilization and is induced by an increase in flagellar $Ca^{2+}$. Our objective was to determine the role of pH in promoting $Ca^{2+}$ signaling of hyperactivated motility. The cell-permeant weak base $NH_4Cl$ (25 mM) increased the curvilinear velocity (VCL: 345.5 ± 3.6 μm/sec vs. 200.7 ± 4.4 μm/sec control) and lateral head displacement of motile bovine sperm (ALH: 14.8 ± 0.2 μm vs. 8.6 ± 0.4 μm control), indicative of hyperactivation. Fluorometric analyses of sperm loaded with 5 μM BCECF-AM or fluo 3-AM, revealed that $NH_4Cl$ evoked elevation of intracellular pH (7.04 ± 0.05 vs. 6.86 ± 0.02 control) and $Ca^{2+}$ (262.5 ± 1.5 nM vs. 43.5 ± 3.5 nM control), respectively. Using single-cell image analysis, increased pH and $Ca^{2+}$ were detected in the flagellum. When extracellular $Ca^{2+}$ was buffered below 50 nM with 10 mM BAPTA, $NH_4Cl$-induced elevation of $Ca^{2+}$ and hyperactivation (VCL 269.5 ± 3.6 μm/sec, ALH 10.4 ± 0.2 μm) were reduced whereas alkalization was unaltered, suggesting that the rise in intracellular pH precedes the influx of $Ca^{2+}$. The $Ca^{2+}$ channel blocker $Ni^{2+}$ (100 μM) also decreased hyperactivation stimulated by $NH_4Cl$. These results indicate that signaling of hyperactivated motility involves activation of pH-sensitive channels in the flagellum that are permeable to $Ca^{2+}$ (NSF MCB-0421855).

518

**Localization and Expression of Plasma Membrane $Ca^{2+}$-ATPase in Bovine Spermatozoa and Testis**

T. Brandenburger, G. Aumüller, B. Wilhelm; Department of Anatomy and Cell Biology, Philipps-University, Marburg, Germany

Mammalian spermatozoa, like other eukaryotic cells, use $Ca^{2+}$ signals to control physiological processes. Calcium entering sperm from outside or from intracellular stores must be returned to the extracellular milieu or the intracellular storage organelles. It is known that the plasma membrane $Ca^{2+}$-ATPase (PMCA) performs the major task of $Ca^{2+}$ clearance in mouse spermatozoa. Mammalian PMCAs are encoded by four separate genes leading to four different isoforms named PMCA 1 to 4. Especially PMCA 4 has been reported to be important for male fertility. In our study we examined the protein- and gene expression of PMCA-isoforms in bovine spermatozoa and bull testis. Performing RT-PCR we could show that PMCA 1, 2 and 4 are expressed in bull testis. In situ-hybridization analysis on bull testis demonstrated a different distribution pattern of PMCA isoforms in the germ cells. Our immunofluorescence- and Western-blotting experiments on bovine epididymal sperm clearly pointed out that the PMCA-isoforms are unequally distributed. Immunoreactivity of PMCA 4 was restricted to the plasma membrane of the midpiece of epididymal sperm, while PMCA 1 immunoreactivity was observed in the acrosomal region, cytoplasmic droplet and the principal piece. We have recently shown that bovine sperm PMCA is stimulated by PDC-109, a secretory protein from bovine seminal vesicles. PDC-109 is located underneath the plasma membrane of the midpiece of bovine sperm once these got in contact with seminal vesicle secretion. Further studies have to elucidate, whether or not PMCA 4 is the isoform which is stimulated by PDC-109.

519

**A Novel Approach to Identify Bovine Sperm Membrane Proteins that Interact with Receptors on the Vitelline Membrane of Bovine Oocytes**

B. J. Pate,[1] K. L. White,[1] D. Chen,[2] P. Desai,[2] K. I. Aston,[1] B. R. Sessions,[1] B. C. Weimer[2]; [1]Animal, Dairy, and Veterinary Sciences, Utah State University, Logan, UT, [2]Center for Integrated Biosystems, Utah State University, Logan, UT

At fertilization, the sperm triggers intracellular calcium oscillations, which are pivotal to oocyte activation and development. The biological significance of these changes in intracellular calcium concentration is not fully understood. A working hypothesis for the interaction between the sperm and the oocyte is that protein ligands on the inner acrosomal membrane of the sperm bind to protein receptors on the oocyte vitelline

membrane. The aim of these experiments is to find and identify the sperm protein ligands involved in bovine sperm-oocyte interactions. In situ fluorescent labeling of proteins and 2-D gel electrophoresis were used to identify specific sperm membrane proteins that bind to membrane proteins in the oocyte vitelline membrane. Zona - free bovine oocytes were incubated in PB1+ containing Alexa Fluor 555 C2-maleimide that binds to cystein residues. Acrosome - reacted sperm were similarly labeled by incubation in Sperm TALP containing CyDye DIGE Fluor Cy5 that binds lysine residues. Unbound label was washed away from the cells, and spermatozoa and oocytes were combined in Fertilization Medium. After allowing cells to bind utilizing their native receptor/ligand complexes, the couplets were transferred into medium containing a bifunctional cross-linker, one end of which binds cystein, the other binding lysine. The cross-linked complexes were then lysed and protein extracts were examined by 2-D gel electrophoresis. The lysine and cystein labels fluoresced at different wavelengths and a scan of the gel using each wavelength was superimposed onto the other and the cross-linked protein spots were identified by their yellow coloration. These spots will be picked and proteins identified by mass spectrometry. This technique will allow identification of proteins from the bovine sperm cell that interact with proteins on the oocyte vitelline membrane.

**Expression of the Y-located TSPY Gene in the Rat Suggests a Role in Chromatin Remodeling during Spermiogenesis**

T. Kido, Y. Lau; Department of Medicine, VA Medical Center, University of California, San Francisco, San Francisco, CA

The Y-located testis specific protein Y-encoded (TSPY/Tspy) genes encode a family of proteins conserved at a carboxyl domain, termed TSPY/SET/NAP1 domain. The human TSPY is a repetitive gene located within the critical region of the gonadoblastoma locus on the Y chromosome (GBY) and has been postulated to be the gene for this oncogenic locus. It is expressed in spermatogonia and spermatids of normal testis and ectopically in gonadoblastoma and testicular germ cell tumors. The rat Tspy, however, is a single copy gene whose product is homologous with the human TSPY only at the SET/NAP1 domain. To investigate the possible function(s) of the rat Tspy, we have studied its expression in postnatal testes using RT-PCR and immunostaining techniques. Our results show that rat Tspy expression starts in the testis around 28 days of age. Immunostaining demonstrate that Tspy is primarily located in the elongated spermatids, different from the expression patterns of human TSPY. Comparative analysis of their promoter sequences reveals that the human TSPY promoter is CpG-rich while the rat Tspy promoter is CpG-poor, but harbors a cAMP responsive element (CRE) essential for many spermatid-specific genes. Interestingly, the rat Tspy co-localizes with the displaced histone H2B in the elongated spermatids. Since the NAP1 is involved in histone accessibility/remodeling, the co-localization of rat Tspy and histone H2B suggests that they might interact in these germ cells. Indeed histone H2B could be co-precipitated with rat Tspy using the GST-pull down assay. These results suggest that the rat Tspy may play a role in spermiogenesis by interacting with histone H2B during the chromatin remodeling in elongated spermatids.

**Role of Type II Phosphatidylinositol 4-Kinase in the Male Germline of *Drosophila***

J. A. Burgess,[1] H. Wei,[2] J. A. Brill[1]; [1]Medical Genetics and Microbiology, University of Toronto, Toronto, ON, Canada, [2]Developmental Biology, Hospital for Sick Children, Toronto, ON, Canada

The lipid phosphatidylinositol 4-phosphate (PI4P) is emerging as a key regulator of cellular trafficking through the secretory pathway. Consistent with this view, at least two mammalian PI4-kinases, PI4KIIα and PI4KIIIβ, have been definitively localized to the Golgi where they regulate Golgi-derived secretory cargo. The *Drosophila melanogaster* ortholog of PI4KIIIβ, *fwd*, is known to be essential for cytokinesis in the male germline, but is otherwise dispensable for development. We have shown that a Fwd-GFP fusion protein localizes to the Golgi, but *fwd* mutants do not exhibit a dramatic loss of PI4P on the Golgi as assessed using a YFP-PH-FAPP reporter construct. This observation suggests that, in *Drosophila*, Fwd might be partially redundant with PI4KIIα, the other Golgi targeted PI4K. *In situ* hybridization analysis revealed that both *PI4KIIα* and *fwd* are expressed in the testes. In order to determine if PI4KIIα is required for spermatogenesis, I generated transgenic flies expressing a *PI4KIIα* RNAi 'snap-back' construct specifically in the testes. Male flies carrying this transgene are sterile and exhibit a late defect in spermatogenesis. Since RNAi might not reveal the null mutant phenotype for PI4KIIα, I used transposon based mutagenesis to generate a series of deletions all starting from the 5'end of *PI4KIIα* extending to varying distances 3'. All deletions cause embryonic lethality, suggesting *PI4KIIα* is an essential gene. To circumvent lethality and investigate the role of PI4KIIα during spermatogenesis, I have constructed a rescue construct that is expressed exclusively in somatic tissue. This construct fully rescues the lethality and will be used to observe the mutant phenotype in the germline. We conclude that PI4KIIα is required for spermatogenesis and likely represents the major PI4K activity during development.

522

**Effects of Roselle and Ginger on Cisplatin-induced Reproductive Toxicity in Rats**

A. Amin, A. Hamza; Biology Department, UAE University, Al-Ain, United Arab Emirates

Cisplatin-based polychemotherapy has been associated with high cure rates for the most frequent malignant diseases seen in young men. In view of these high cure rates, increasing clinical importance is now being attached to chemotherapy-induced fertility disorders. Cisplatin is known to induce cellular damage to testis and disrupt spermatogenesis and to cause other reproductive dysfunctions in both experimental animals and human. In this report, we used an acute cisplatin-toxicity rat model (10 mg/kg b.wt.) to analyze the protective effects of *Hibiscus sabdariffa* (HS) and *Zingiber officinalis* (ZO) against cisplatin-induced reproductive toxicity. Oral administration of extracts of HS or ZO (1 g/kg/day) for 26 days, that began 21 days before single, cisplatin intraperitoneal injection, produced significant protection of reproductive function. Both extracts reduced the extent of cisplatin-induced reproductive toxicity, as evidenced by decreases in sperm abnormality and increases in sperm motility. Cisplatin-induced alterations in testis lipid peroxidation were also markedly improved by test extracts, and cisplatin-induced alterations in the testis antioxidation defense system were profoundly prevented by extracts. In groups where cisplatin was combined with either HS or ZO, antioxidation enzymes like superoxide dismutase, reduced glutathione, and catalase were significantly elevated compared to the cisplatin-treated group. The results provide further insight into the mechanisms of cisplatin-induced reproductive toxicity and confirm the antioxidant potential of both HS and ZO.

### *C elegans* Sperm Cells are Damaged by Hypoxic Exposure

D. L. Miller, M. B. Roth; Basic Sciences, Fred Hutchinson Cancer Research Center, Seattle, WA

Cellular damage resulting from oxygen deprivation, or hypoxia, can occur during decreased oxygen availability or upon reoxygenation (reperfusion injury). It is not understood why oxygen deprivation results in cellular damage, which specific oxygen concentrations cause damage or, more importantly, how such damage could be prevented. We have been investigating the cellular response to various oxygen tensions in *C. elegans*. We show that a particular cell type, sperm, is uniquely susceptible to damage when exposed to particular hypoxic oxygen tensions. Although they are in different developmental states, hermaphrodite spermatozoa and male spermatids are equally sensitive to hypoxic exposure. Damaged sperm exhibit a motility defect *in vivo,* morphological abnormalities and fail to complete spermiogenesis *in vitro.* We are utilizing the powerful developmental genetics of *C. elegans* to explore sperm cell responses to hypoxia and mechanisms to prevent damage caused by decreased oxygen availability.

### Coxsackievirus and Adenovirus Receptor (CAR) is Expressed in Male Germ Cells and Forms a Complex with the Differentiation Factor JAM-C in mouse Testis

M. Mirza,[1] L. Philipson,[2] R. F. Pettersson,[1] K. Sollerbrant[1]; [1]Ludwig Institute for Cancer Research, Stockholm, Sweden, [2]Department of Cell and Molecular Biology, Karolinska Institute, Stockholm, Sweden

The coxsackievirus and adenovirus receptor (CAR) is a cell surface protein that belongs to the CTX subfamily within the immunoglobulin superfamily. CAR, like several of the CTX family members, is an adhesion protein and a component of tight junctions. CAR is expressed in at least two membrane-bound isoforms that differ only at the C-terminus of the intracellular tail. We here present evidence showing that CAR is expressed in male germ cells from mice, rats and humans. CAR was detected already in round spermatids in the testis and in purified, mature spermatozoa. The two isoforms of CAR occupied different subcellular sites in the acrosomal region of the spermatozoa. Interestingly, CAR was exposed on the cell surface of acrosome-reacted but not acrosome-intact cells suggesting that CAR may have a role in the fertilization process. LNX and LNX2, two scaffolding proteins that we previously identified capable of binding to CAR, was also found to be expressed in the spermatozoa. Finally, we find CAR to form a protein complex with the spermatid-differentiation factor JAM-C. Together these findings imply a function for CAR in male fertility. These results also suggest that CAR is not accessible to adenovirus-based gene therapy vectors in the spermatozoa, and we therefore believe that the risk of CAR-mediated germ-line infection is low.

525

### Identification of Aquaporins (AQPs) in the Male Reproductive Tract of Adult Rats

L. Hermo,[1] A. M. Murphy,[1] B. Dayanandan,[1] J. Cloutier,[2] C. A. Mandato[1]; [1]Anatomy and Cell Biology, McGill University, Montreal, PQ, Canada, [2]Neurology and Neurosurgery, McGill University, Montreal, PQ, Canada

In the male reproductive tract (MRT), water balance plays an important role in sperm transport, concentration and maturation. In many biological systems, water passes through membranes slowly by way of simple diffusion, however, certain specialized membranes exhibit a much higher capacity for water permeation due to the presence of transmembrane water channels known as AQPs. To date, several of the diverse AQP family members have been identified in the adult MRT, however, considering the extensive distribution of AQPs in the kidney and the similar embryological derivation of the two organs, we hypothesize that other AQPs family members will be expressed in the MRT. In this study, we used specific RT-PCR primers corresponding to each member of the AQP family to define their expression in the MRT. The RT-PCR results confirmed the presence of AQP 7, AQP 8 and AQP 9 transcripts in the testis, AQP 1 and AQP 9 transcripts in the efferent ducts, as well as AQP 1, AQP 3 and AQP 9 in the epididymis. In addition to these aquaporins, mRNA for AQP 5 and AQP 7 were found to be expressed in the epididymis, while AQP 7 was also present in the efferent ducts. In situ hybridization (ISH) confirmed the presence of the AQP 5 mRNA in the epididymal epithelium, using DIG-labeled antisense and sense (negative control) AQP 5 specific riboprobes. The antisense probe detected AQP 5 mRNA expression in the epididymal epithelium, with a strong reaction being present in the epithelial principal cells of all regions. In summary, our data revealed the presence of two as yet undefined AQPs (AQP 5 and 7) in the epididymis and AQP 7 in the efferent ducts.

### Initial Characterization of the Testis Specific Serine Kinases (TSSK) Family of Proteins in Mature Mouse Sperm

J. Sosnik, M. S. Reesse, P. E. Visconti; Veterinary and animal Sciences, University of Massachusetts, Amherst, MA

Post translational modifications of proteins through phosphorylation play a role in many cellular processes such as the transduction of extracellular signals, intracellular transport, and cell cycle progression. Our group is interested in the study of signaling events that are involved in sperm differentiation and function. Recently, a novel family of ser/thr kinases (testis specific serine kinases (Tssk)) has been found postmeiotically expressed in the male germ cells. The conserved testicular expression pattern of Tssk genes as well as the importance of phosphorylation in signaling processes strongly suggests that Tssk(s) have important role(s) in germ cell differentiation and/or sperm function. In addition, mice null for one member of this family (mTssk6) has recently been described having a male infertile phenotype (Spiridonov et al., 2005). In this work, using antibodies that recognize all the members of the Tssk family as well as some specific antibodies against individual members of the family, we show through immunofluorescence and western blots the presence of several members of the Tssk family in mature mouse sperm. This constitutes a first step to advance in the understanding of the role of this kinase family. Further biochemical characterization, as well as the analysis of null mutants (KO) of Tssk(s) will be very important for the analysis of the functions of Tssk's. If the predicted importance of Tssk's in spermatogenesis and/or sperm function is confirmed, this research can ultimately help to design novel human contraceptives.

### Parthenogenetic and Nuclear Transfer Embryo Development of Bovine Oocytes Denuded and Centrifuged at Different Time during Maturation

G. P. Li, T. D. Bunch, K. L. White, B. R. Sessions, K. I. Aston, B. J. Pate; Animal Dairy and Veterinary Sciences, Utah State University, Logan,

UT

This study was designed to examine the effects of removal of cumulus cells and/or centrifugation of maturing bovine oocytes on maturation and subsequent parthenogenetic and nuclear transfer embryo development. At 0, 4, 8, and 15 hr after the beginning of maturation the cumulus cells were removed and some oocytes were centrifuged followed by further maturation to 24 hr. The results showed that removal of cumulus cells or centrifugation of the denuded oocytes had no effect on the maturation rates except in the group of oocytes denuded and centrifuged at the beginning of maturation in which only 50% oocytes expelled the first polar body (PB1). However, denuding and centrifugation did affect the pattern of spindle microtubule distribution and division of chromosomes. Swollen and loose spindles were observed in anaphase I and telophase I oocytes. Activated oocytes denuded at IVM 8 hr whether centrifuged or not resulted in the lowest development (3.0%). The highest parthenogenetic development to blastocyst (17.6%) was observed in the group of oocytes denuded at the onset of maturation. Centrifugation of oocytes denuded before 8 hr of IVM was detrimental to parthenogenetic development. After nuclear transfer, centrifugation of oocytes denuded at 4, 8, and 15 hr IVM resulted in numerically lower or significantly lower blastocyst development than the non-centrifuged oocytes. However, significantly higher blastocyst development occurred in centrifuged oocytes when they were denuded at the beginning of maturation. In conclusion, the removal of cumulus cells and centrifugation of denuded oocytes affect oocyte spindle patterns. Oocytes denuded and centrifuged at different times during maturation are affected differently in terms of embryo development following parthenogenetic activation or nuclear transfer.

### *in vitro* Maturation of Human Oocytes in Barium Alginate Membranes

M. Torre,[1] E. Albani,[2] P. Levi Setti,[2] E. Munari,[3] U. Conte,[1] S. Villani,[4] M. Faustini,[5] G. Ricevuti,[1] E. Benzoni,[3] D. Vigo[3]; [1]Dipartimento di Chimica Farmaceutica, Università di Pavia, Pavia, Italy, [2]Istituto Clinico Humanitas, Rozzano (MI), Italy, [3]Dipartimento di Scienze e Tecnologie Veterinarie per la Sicurezza Alimentare, Università degli Studi di Milano, Milano, Italy, [4]Dipartimento di Scienze Sanitarie Applicate e Psicocomportamentali, Università di Pavia, Pavia, Italy, [5]Dipartimento di Scienze e Tecnologie Veterinarie per la Sicurezza Alimentare, Università degli Studi di Milano, Milano, Italy

Aim of the present work was to evaluate the maturation yields of human oocytes co-cultured in a pseudo-follicular granulosa cells structure. Germinal vesicles (GV) and granulosa cells were recovered from gonadotropin-treated women: GV were suspended in Ménezo Upgraded B2 INRA Medium and splitted into two groups: micro drops culture (control group) and three-dimensional co-culture (3D) group. Cumulus cells were harvested and resuspended in Ham's F10 with albumin medium at the concentration of $20 \cdot 10^6$ cells/ml. A saturated solution of $BaCl_2$ was added to the granulosa cells to a concentration of 20 mM. The suspension was then extruded through a needle and dropped into a medium viscosity sodium alginate solution 0.5% in culture medium (Ham's F10 with albumin). A single germinal vesicle was injected by means of a sterile capillary in each capsule that was finally incubated in a culture well containing 500 µl of the same culture medium at 37°C and 5% $CO_2$. GV were cultured without their cumulus masses in microdrops (25 µl) of Ménézo medium. Dishes were placed into incubator at 37°C, 5% $CO_2$. After 24 and 48 hours of culture, oocytes were classified as immature (metaphase I), or mature (metaphase II). Logistic regression shows a relevant association between success in oocytes maturation and the new culture system. Maturation probability is almost three folds higher in three-dimensional co-culture after 24 hours of incubation (P=0.001). At 48 hours the probability of maturation is greater in three-dimensional co-culture than in micro-drops one (P<0.001). A significant increase in oocyte maturation yields was obtained (co-culture: 90.3%; microdrop: 52.0%, Odds Ratio 8.51; P<0.001) in 3Dl co-culture. The risk of maturation in co-cultured oocytes is eightfold with respect to a traditional maturation technique, permitting a high number of gametes available for *in vitro* fertilization programs.

### Molecular and Genetic Interactions of SAX-7 with the Dystrophin-Associated Proteins, Gamma-Syntrophin and KIN-4, in the Germline

K. M. Baker, K. Opperman, L. Chen; University of Minnesota, Minneapolis, MN

The L1 family of cell adhesion molecules (L1CAMs) has been implicated in neuronal development. Non-neuronal L1CAM expression and function have been identified recently. However, their roles and mechanisms are poorly understood. We have identified requirement for the *C. elegans* L1CAM homologue, SAX-7, in multiple non-neuronal tissues, including the germline. To better determine SAX-7 functions and mechanisms, we performed a directed yeast two hybrid screen for PDZ proteins that interact with the SAX-7 consensus PDZ binding motif. We identified two proteins, gamma-syntrophin and KIN-4, both of which are associated with the dystrophin-glycoprotein complex (DGC) (1, 2). Reduced levels of gamma-syntrophin or KIN-4 accomplished by RNAi in *sax-7* mutant animals but not in wild-type animals resulted in obvious germline defects. This genetic interaction suggests that the molecular interaction between SAX-7 and gamma-syntrophin and KIN-4 is functionally significant, particularly with respect to germline development. 1. Piluso et al. (2000) J. Biol. Chem. 275: 15851-15860; 2. Lumeng et al. (1999) Nat. Neurosci. 2: 611-617.

### Characterization of Src Family Kinase Signaling in Echinoderm Egg Activation

I. K. Townley, M. Raisch, A. Reade, K. Foltz; Molecular, Cellular and Developmental Biology, UCSB, Santa Barbara, CA

In echinoderms (sea urchin and starfish), a current model of egg activation at fertilization involves the stimulation of at least one Src family kinase (SFK) and subsequent activation of phospholipase C gamma (PLCγ). PLCγ generates inositol trisphosphate ($IP_3$) causing release of $Ca^{2+}$ from the egg ER. Inhibition of SFK or PLCγ activity blocks $Ca^{2+}$ release. The SFK activity is upstream of PLCγ, but whether there is direct or indirect interaction between the two proteins is unknown as are the identities of other SFK substrates and interacting proteins. Immunofluorescence microscopy using affinity purified antibodies revealed that the SFKs are localized to the plasma membrane before and after fertilization, albeit with distinct labeling patterns, while PLCγ is recruited to the plasma membrane after fertilization. Biochemical methods such as co-purification via fractionation of eggs, affinity chromatography, and co-immunoprecipitation indicate that the SFK and PLCγ proteins interact in a fertilization-dependent manner, consistent with the immunolocalization data. Further, additional proteins that interact with the SFK in a fertilization-dependent manner have been detected and we are identifying these proteins. Collectively, the data suggest that there is a signaling complex in eggs that exhibits dynamic composition before and after fertilization. Biochemically, this complex can be isolated in a detergent resistant membrane fraction (lipid raft). Experiments are underway to test the effects of disrupting the signaling complex during fertilization. Supported by an NSF award to

KRF.

**Proteomic Analysis of Signaling at Egg Activation and during the First Mitotic Cell Cycle**

M. M. Roux, K. R. Foltz; MCDB, UCSB, Santa Barbara, CA

Post-translational modifications of the maternal proteome drive cellular activity during egg activation and throughout early embryogenesis. Changes in phosphorylation of protein modules are necessary/sufficient for successful fertilization and initiation of the developmental program. The Mitogen Activated Protein Kinase (MAPK) cascade is a highly conserved signal transduction module responsible for integrating extracellular signals whose output regulates many cellular activities. In unfertilized sea urchin eggs, constituitively active MAPK results in arrest in a haploid G0 stage of the cell cycle. Oocyte specific MAPK Kinase Kinase (Mos) is the best candidate for maintainence of this arrest. Mos has been shown to be the key component of Cytostatic Factor (CSF) which is responsible for Metaphase II arrest in vertebrate oocytes. We have recently identified and cloned the purple sea urchin (*Strongylocentrotus purpuratus*) Mos and shown that it contains an extended N-terminal domain that may be responsible for this Echinoderm specific arrest. Upon fertilization, degradation of Mos inactivates MAPK allowing for re-entry into the mitotic cell cycle. Loss of MAPK activity is sufficient for successful progression into the first mitotic S-phase. A proteomics approach has been used to identify targets of the MAPK cascade involved in release from G0 and initiation of DNA synthesis. Echinoderms naturally spawn large batches of mature eggs highly synchronized in this G0 pronuclear stage, eliminating complications stemming from meiotic regulation of this same pathway. MAPK activity can be controlled in these eggs through natural fertilization or chemical inhibitors both *in vivo* and *in vitro*. Using 2D electrophoresis, phosphorylation dependent imaging and Q-Tof MS/MS, a reproducible subset of proteins in the egg have been identified as putative targets of MAPK signaling during mitotic re-entry. The roles of these protein are currently under investigation Funding: NSFGRF, NSF IBN-0415581

**Computer Modeling of CUB Domains in Proteases: Binding and Enzymatic Predictions**

R. T. Almaraz, G. A. Barisone, J. L. Hedrick; Animal Science, University of California, Davis, CA

The vitelline envelope glycoproteins of amphibian eggs are processed by serine active site proteases containing CUB domains. These proteolytic modifications, namely the processing of ZPC by oviductin and of ZPAX by the hatching enzyme, are essential to fertilization and development. We hypothesize CUB domains provide specific carbohydrate binding functions to theses proteases, therefore making catalysis more efficient. To test this hypothesis, we performed 3D modeling studies and carbohydrate docking calculations on oviductin. The protease subunit of oviductin was modeled using α-chymotrypsin (pdb ID: 5cha) as a template. CUB1 was modeled after Masp2 (pdb ID: 1NTO-G) and CUB2 after C1s (pdb ID: 1NZI-A). Egg envelope oligosaccharides were used in the docking calculations. A putative carbohydrate binding site was identified on CUBs with binding specificity for high mannose oligosaccharides. We expressed and purified CUB domains for binding experiments in *E. coli*. The expressed oviductin CUB domain bound to egg envelopes. These results support our hypothesis that CUB domains, by binding to oligosaccharide moieties can act as "tethers", thereby assisting the protease domain in locating and hydrolyzing its particulate glycoprotein substrate. CUB domains are a widespread protein module, are involved in many biological processes, and are present in all metazoans. We expect our oviductin model will contribute to understanding CUB structure-function relations.

**Confocal Scanning Microscopy of Fluorescent Lectin-labeled Ascidian Eggs**

M. M. Botkin, R. A. Koch; Biological Science, California State University, Fullerton, Fullerton, CA

The purpose of this project is to determine the presence and localization of components of the extracelluar matrix in *Ascidia ceratodes* eggs. The ascidian egg complex, surrounded by ovijelly in the oviduct and immediately upon ovulation, is composed of a six-part vitelline coat having four non-cellular layers and two cellular components bounding the central oocyte. The non-cellular layers are the central dense layer, outer fibrous layer (OFL), inner fibrous layer, and perivitelline fibrous layer (PVFL). The cellular components consist of the follicle cells on the outer surface and test cell embedded in the PVFL and adjacent to the oocyte. Single and double labeling experiments were performed. Ascidian eggs, isolated by needle dissection, were exposed to pH 6.0 artificial seawater (ASW) to remove ovijelly, hydrated in pH 8.0 ASW, fixed in 3% formaldehyde, incubated in fluorescently labeled lectins, and photographed with a confocal microscope. Succinylated-ConA, SBA, and LPA each labeled the surfaces of follicle and test cells. UEA-1 strongly labeled the follicle cells. PNA and MPA weakly labeled the follicle cells. Succinylated-WGA labeled the OFL and follicle cells. Thus, we conclude that α-mannose, α-glucose, α & β GalNAc, α & β-galactose, GalNAc (α1, 3) Gal, and sialic acid are located on follicle and test cell surfaces. High amounts of α-L-fucose and Fuc (α1, 2) Gal (β1, 4)-GlcNAc are present on the follicle cells, whereas α & β-galactose, α GalNAc, and Gal (β 1, 3) GalNAc are weakly present on the follicle cells. Finally, β-GlcNAc and (GlcNAc-β (1, 4) GlcNAc) $_{1\text{-}4}$ are present on the OFL, surface of the follicle cells, and ovijelly. Many of these glycans co-localize. Our knowledge of these carbohydrate distribution groups will help us understanding the conditions influencing sperm-egg binding and sperm penetration. (Funded by NIH R25-GM56820)

534

**Proteomics of Fish Egg Cortical Granules III (Phosphorylated Proteins)**

K. Murata,[1] Y. Xie,[2] S. Yin,[2] J. Loo,[3] J. L. Hedrick[1]; [1]Animal Science, University of California, Davis, CA, [2]Biological Chemistry, University of California, Los Angeles, CA, [3]Biological Chemistry; Chemistry and Biochemistry, University of California, Los Angeles, CA

Egg cortical granule components play essential roles in fertilization and development in all animals. When released into the perivitelline space during the cortical reaction, these components modify the egg envelope thereby regulating sperm egg interaction (polyspermy block) and the relation between the environment and developing embryo (hardening, alternation of envelope molecular permeability). As a global strategy to determining the total macromolecular composition of cortical granules, a proteomics strategy was used. Due to advantages of size and ease of handling, Chinook salmon eggs were used as the source of cortical granule material. After activation of eggs with cold water, the perivitelline space fluid was collected by microdissection of the egg envelope (chorion). The perivitelline space fluid was dialyzed against IEF buffer, the components

separated by two-dimensional polyacrylamide gel electrophoresis, and stained with SYPRO Ruby. About 285 spots were detected. The same gel was restained with Pro-Q Diamond to detect the phosphorylated proteins. About 115 spots were detected. We analyzed the phosphorylated proteins using MS methods and preliminarily identified 48/115 spots. Supported in part by USDA 2003-35203-12831.

## Cell Polarity I (535-549)

535

### ADF/Cofilin and Neuronal Polarity

K. C. Flynn,[1,2] J. R. Bamburg[1,2]; [1]Cell and Molecular Biology Program, Colorado State University, Fort Collins, CO, [2]Program in Molecular, Cellular, and Integrative Neurosciences, Colorado State Univeristy, Fort Collins, CO

In hippocampal neurons, the establishment of neuronal polarity occurs when the axon differentiates from one of several immature neurite processes. The family of Rho GTPases play an essential role in the initial signaling events during axon formation. In addition, a local change in actin filament dynamics in one growth cone specifies axon formation. However, the actin regulatory proteins functioning downstream of the Rho GTPases have not been identified. Likely candidates are the proteins in the actin depolymerizing factor (ADF)/cofilin (AC) family, which enhance actin filament turnover by severing filaments and increasing depolymerization rates from their minus end. Hippocampal neurons express both cofilin and ADF in about a 4:1 ratio. Here we show enhanced AC activity in engorged growth cones occurred prior to axonogenesis, although not all neurites with engorged growth cones developed into axons. Active AC remained enriched in the axonal growth cone of polarized neurons. Induction of multiple axons occurred in neurons overexpressing wildtype *Xenopus* AC (XACwt), and to a lesser degree in neurons overexpressing the non-phosphorylatable but active XAC(S3A), suggesting AC phosphocycling may be important in axonogenesis. Conversely, overexpression of inactive XAC(S3E) did not significantly affect axonogenesis. Reduction in cofilin expression by adenoviral-mediated siRNA depressed axonogenesis and neurite outgrowth, both of which are rescued by coexpression of XACwt.. Growth cone size was reduced in neurons with decreased cofilin and was increased in neurons overexpressing XACwt. Taken together, these results suggest that AC activity in growth cones regulates axon specification. (Supported by NIH grants GM35126, NS40371 and NS43115).

### Mechanism of Polarized Protrusion Formation on Neuronal Precursors Migrating in the Developing Chicken Cerebellum

A. Sakakibara, A. F. Horwitz; Department of Cell Biology, University of Virginia, Charlottesville, VA

Cell migration *in vivo* relies on the integration of extracellular signals, which are presented in a spatio-temporal manner in a three-dimensional environment. To elucidate the mechanism by which cells undergo migration *in situ,* we developed a novel imaging system for observing the migration of neuronal precursors in the developing cerebellum. The combination of electroporation-based gene transfer with an organotypic explant culture enabled us to label rhombic lip-derived neuronal precursors with GFP and subsequently image their dynamics. With this system, we observed that the cells show an unusually long polarized protrusion. We then studied the signaling responses that lead to this high degree of polarity. First, we demonstrated a critical role for Cdc42 in the maintenance of a monopolar shape *in vivo.* Expression of dominant negative (N17) Cdc42 abrogated polarity and resulted in rounded cells. However, perturbing downstream polarity effectors of Cdc42, e.g., the aPKC/Par3/6 complex, or APC, did not disrupt the unipolar morphology, suggesting that other downstream effectors might be involved. We next investigated the PI3-kinase pathway, which is implicated in polarized gradient sensing in *Dictyostelium* and neutrophils. Surprisingly, inhibition of PI3-kinase up-regulated non-localized branches off the long protrusion but showed no major polarity defect. Overexpression of phosphatase-dead PTEN enlarged the tip of the protrusions whereas wild-type overexpression narrowed it. Taken together this suggests that the primary function of PI3-kinase in these cells is to target active protrusions to the tip of leading process, and that PTEN may control the magnitude of protrusions rather than their localization. Finally, we showed that receptor tyrosine kinases and Rac are required for generation of the protrusions. Our results show that mechanisms of cell polarization *in vivo* share some properties with *in vitro* studies but also reveal important differences.

537

### Shootin1 is Involved in Spontaneous Neuronal Polarization

M. Toriyama,[1] T. Shimada,[1] K. B. Kim,[1] M. Mitsuba,[1] E. Nomura,[1] K. Katsuta,[1] P. Roepstorff,[2] N. Inagaki[1]; [1]Division of Signal Transduction, Nara Institute of Science and Technology, Ikoma, Japan, [2]Department of Biochemistry and Molecular Biology, University of Southern Denmark, Odense, Denmark

Most neurons form a single axon and multiple dendrites to develop polarity. However, the mechanisms by which neurons generate only one axon to break symmetry remain poorly understood. In order to identify molecules that are involved in neuronal polarization, we performed two types of screenings of the proteome in cultured rat hippocampal neurons. One is the screening of proteins enriched in axons, and 200 positive protein spots were detected by the screening of 5,164 proteins. The other is screening of proteins up-regulated during the initial step of neural polarity formation (from stage 2 to stage 3); 277 positive protein spots were detected out of 6,197 proteins. Mass spectorometric analysis identified a novel brain specific molecule shootin1 that was detected by both screenings. Expression level of shootin1 became up-regulated and highly localized axonal growth cones during neuronal polarization. After synapse formation, shootin1 was disappeared at axonal terminus. Before polarization shootin1 began fluctuating accumulations in multiple growth cones of undifferentiated neurites, coincident with competitive elongation of the neurites. The nascent axon finally wins in a competition for exclusive and continuous shootin1 accumulation. Overexpression of shootin1 led to formation of multiple axons, whereas suppression of endogenous shootin1 by siRNA delayed neuronal polarization. Accumulated shootin1 in the growth cones recruited phosphatidylinositol 3-kinase (PI3-K) activity and mPar3 (previously reported involved in cell polarization) and induced axon formation. These observations suggest a model in which competitive interactions involving shootin1 among neurites ensure the generation of a single axon which is necessary for spontaneous symmetry-breaking in neurons.

538

### The Polarity Protein PAR-3 Mediates Dendritic Spine Morphogenesis Through Regulation of the Rac GTPase

H. Zhang, I. G. Macara; Center for Cell Signaling, University of Virginia, Charlottesville, VA

PAR-3 has been implicated in cell polarity establishment in many contexts, but the key molecular functions of the protein have been unclear. Relatively little is known about PAR-3 in neuronal polarization, and no role has been reported for any PAR protein in dendritic spine formation, a process central to the establishment of the brain circuitry. Here we show that PAR-3 is essential for dendritic spine morphogenesis in primary hippocampal neurons. Knockdown of PAR-3 expression results in the formation of multiple filopodia- and lamellipodia-like dendritic protrusions, a phenotype reminiscent of neurons expressing constitutively active Rac. PAR-3 regulates spine formation by binding the Rac GEF, TIAM1, and spatially restricting it to dendritic spines. Our data show a novel role for PAR-3 in dendritic spine morphogenesis and suggest that a principal function of PAR-3 in mammalian cell polarization is the control of actin cytoskeleton remodeling through spatial restriction of Rac-GTP formation.

539

### Schwann Cell Polarity

C. Berti, L. Wrabetz, M. L. Feltri; San Raffaele Scientific Institute, DIBIT, Milano, Italy

Three protein complexes generate polarity in several cellular contexts: 1) Par3/Par6/aPKC, 2) Crb/Pals1/PATJ-MUPP1, 3)Scrib/mDlg/mLgl. They are highly conserved throughout evolution and are part of tight (TJ) and adherens junctions (AJ). Mutations in components of these complexes lead to defects in polarity. In vertebrates, they control polarity of several cell types, including epithelia, astrocytes and neuronal growth cones, where the complex is found at the leading edge. Schwann cells surround axons and form myelin in the peripheral nervous system and, like neurons, are highly polarized cells. Similar to epithelial cells they have an apical surface facing the axon and a basal surface facing the basal lamina, but in addition they must polarize along the longitudinal axis. To explore the molecular mechanisms controlling polarity in Schwann cells, we investigated the expression of polarity complexes in sciatic nerve teased fibers and myelinating explant co-cultures. In vivo, we confirmed previous results and characterized new TJ components and polarity markers, such as PARs, claudins and claudin-associated PDZ proteins, and show that they localize in distinct regions of non-compact myelin. Surprisingly, members of the same complexes in epithelial cells do not always colocalize in Schwann cells in vivo, suggesting that Schwann cells exploit polarity molecules in a unique way. Furthermore the PAR complex may be important for myelination, as specific inhibition of aPKCζ using one of its pseudosubstrates in myelinating Schwann cells-axon co-cultures showed a reduction in the ability of treated cultures to form myelin. Schwann cells specific inhibition of aPKCζ will be performed to evaluate if the effect is Schwann cells intrinsic.

540

### Unravelling the Role of Atypical PKC-Par3-Par6 Protein Complex in Neural Proliferation and Polarity

V. Broccoli,[1] V. Belloni,[1] R. Tomasoni,[1] A. Le Bivic,[2] J. Wijnholds[3]; [1]Stem Cell Research Departement, San Raffaele Scientific Institute, Milan, Italy, [2]Developmental Biology Institute of Marseille, Faculte des Sciences de Luminy, Marseille, France, [3]Netherlands Ophthalmic Research Institute, Amsterdam., The Netherlands

Cell polarity is an essential mechanism that regulates cell adhesion and migration properties and allows compartmentalization of cell domains with specific functions. In many different cell types, cellular polarization is initiated by the restricted localization of a protein complex composed of an atypical protein kinase C (aPKCz or l), Par3, Par6. Here, we show the presence of this complex in the embryonic mammalian nervous central system and its restricted localization on the apical side of the neural progenitors. This protein complex was co-localizing with cell junction structures. We propose that this protein complex is necessary for inducing and maintaining cell-junction formation during neural tube shaping. Moreover, aPKC-Par3-Par6 complex was detected in embryonic neural stem cells. We inhibited the protein complex function by using a specific inhibitor of aPKC kinase activity. This treatment causes a general loss of proliferative activity on neural stem cells. Interestingly, aPKC inactivation leads to GSK-3b hypophophorylation and consequently to a inactivation of b-catenin. Thus, accordingly, we found that aPKC is able to bind directly to GSK-3b and to regulate its phosphorylation level. These findings reveal an unpredicted role played by the aPKC-Par3-P6 in regulating neural proliferation whose molecular mechanisms in vivo should be still carefully investigated.

541

### Annexin2 is Required for Lumen Formation in MDCK Three-dimensional Cell Cultures

F. Martin-Belmonte,[1] V. Gerke,[2] K. E. Mostov[1]; [1]Anatomy, University of California, San Francisco, San Francisco, CA, [2]Center for Molecular Biology of Inflammation, Institute for Medical Biochemistry, Munster, Germany

Lumen formation is a fundamental step in the development of the structural and functional units of glandular organs, such as kidney tubules and mammary acini. The Madin-Darby canine kidney (MDCK) epithelial cell line forms acinar structures called cysts, when embedded in a three-dimensional (3D) extracellular matrix (ECM) and represents an excellent model to analyze epithelial morphogenesis in vitro. MDCK cysts are generated from a 3D cluster of unpolarized cells that does not have a central lumen. To form the central lumen, unpolarized MDCK cells first acquire apical-basal polarity and then form de novo a central lumen surrounded by an apical belt of actin cytoskeleton. In epithelial cells, the actin cytoskeleton is regulated by the Rho family of small GTPases including the prototypical members RhoA, Rac1 and Cdc42. To exert their function, the Rho GTPases must be activated in specific plasma membrane regions. Although it has been proposed that the localization of these proteins is one of the main events that regulate their activity, the mechanisms that control the localization of the Rho GTPases are still poorly understood. Here, we show that the phosphatidylinositol (4,5) bisphosphate binding protein annexin2 tethers Cdc42 to the apical membrane of epithelial MDCK during cysts formation. Furthermore, when the function of annexin2 is disrupted by the expression of the dominant negative forms of this protein, Cdc42 is mislocalized causing the disorganization of the apical actin belt and the inhibition of central lumen formation.

542

### Examination of Mammalian Par 6 Nuclear Function

E. G. Cline, W. J. Nelson; Molecular and Cellular Physiology, Stanford University, Stanford, CA

In mammalian epithelial cells, Par 6, Par3, and aPKC form a complex localized to cell membranes in the region of the tight junction. This complex is important for cell polarity. Immunofluorescence studies of MDCK II cells with an affinity-purified antibody have shown that Par 6-alpha is localized not only to the apical junction region of cells, but also in distinct "speckles" in the nucleus. This nuclear localization has been confirmed biochemically and in several different cell lines. Nuclear localization of Par 6 suggests a role in gene expression either through transcription or

mRNA maturation and transport. Fluorouridine incorporation assays and GAL-4 transactivation assays indicate that Par 6 is not involved in activating transcription. Par 6 nuclear speckles colocalize with the spliceosome component SC35 and with overexpressed Paraspeckle Protein -1, suggesting a role in post-transcriptional mRNA biogenesis. The Par 6 nuclear staining pattern also changes in response to transcription inhibiting drugs in the same manner as proteins involved in splicing. Expression of the HTLV-1 viral transcriptional transactivation protein Tax, which interacts with Par 6, causes aggregation of transcription and splicing factors, and Par6 in the nucleus. Taken together, these results indicate roles for Par6 in gene expression and mRNA biogenesis.

**Hepatic Progenitor Cells Establish Epithelial Polarity in the Three Dimensional Culture**

N. Tanimizu,[1] A. Miyajima,[2] K. Mostov[1]; [1]Anatomy, University of California San Francisco, San Francisco, CA, [2]Institute of Cellular and Molecular Bioscience, University of Tokyo, Tokyo, Japan

The mammalian liver contains two types of epithelial cells, hepatocytes and cholangiocytes. Both of them originate from hepatoblasts. Mouse cholangiocyte differentiation around portal vein starts at about embryonic day 15. Immature cholangiocytes make ductal plates, generate the apical lumen between two cell layers, and then form bile duct tubules. Several mutant mice and human infants have been reported to show defects in bile duct development, which cause cholestasis, fibrosis, and cirrhosis of liver, though the functions of the mutated genes in cholangiocyte morphogenesis have not been clear. One of the reasons is that there is no *in vitro* culture system applicable to study cholangiocyte differentiation from hepatic progenitor cells. We established a liver progenitor cell line, HPPL, from mouse hepatoblasts (1). Since HPPL preserves proliferative capability and multi-differentiation potential of hepatoblasts, it is useful to study the process of bile duct formation from their progenitors. We are applying the three dimensional culture system in which cells grow in a gel of extracellular matrix proteins to understand the mechanism of cholangiocyte polarization and tubulogenesis. In collagen gel, HPPL proliferate and form extended structures by the stimulation of HGF. However, these structures did not have an apical lumen. On the other hand, when HPPL was kept in the mixture of Matrigel and collagen, some of HPPL formed cysts that had the apical lumen. These cysts expressed cytokeratin 19, which is a marker of cholangiocytes, suggesting HPPL developed the epithelial polarity as cholangiocytes. Considering that cholangiocytes are associated with the basement membrane during embryonic development, the interaction between HPPL and components of Matrigel induced the polarization of HPPL in the culture. 1. **Cdc42 Regulation of Atypical Protein Kinase C**

S. X. Atwood, K. E. Prehoda; Institute of Molecular Biology, University of Oregon, Eugene, OR

Atypical protein kinase C (aPKC) is a key regulator of cell polarity. aPKC forms a complex with Bazooka/Par-3 and Par-6 that functions to separate apical and basolateral plasma membrane domains of epithelia and asymmetrically localize cell fate determinants in stem cells. The small Rho GTPase Cdc42 interacts with this complex through an interaction with Par-6 that is thought to be important for regulating aPKC activity. However the mechanism by which Cdc42 alters aPKC kinase activity through Par-6 is poorly understood. We show that binding of Cdc42 does not remodel the Par-6/aPKC complex, but instead modulates a secondary interaction between the CRIB-PDZ protein interaction domain of Par-6 and aPKC. We also show that Cdc42 localizes to the cytoskeleton and not the membrane of Drosophila embryos where presumably aPKC can bind to and phosphorylate its ligands. Our data provides evidence for an allosteric model for the regulation of aPKC activity by Cdc42 as well as a novel model for the localization of the Par-6/aPKC complex to the cell periphery.

**Evidence for Epithelial-to-Mesenchymal Transition in a Mouse Model for Autosomal Recessive Polycystic Kidney Disease**

S. P. Ryan, C. Carlin; Dept of Physiology and Biophysics, Case Western Reserve University, Cleveland, OH

Epithelial-to-mesenchymal transition (EMT) is a highly regulated biological event with important roles during embryonic development, tissue repair, and tumor metastasis. EMT is well studied in the kidney, where epithelial cells lining nephrons are either shed into the lumen and die, or transition to fibroblasts, following renal injury. Autosomal Recessive Polycystic Kidney Disease (ARPKD), characterized by epithelial cell hyperproliferation and acquisition of a secretory phenotype leading to cyst formation, is a devastating disease affecting approximately 1:20,000 persons annually. We hypothesize that ARPKD represents a failed attempt at EMT. If true then cystic cells should exhibit a subset of characteristic EMT features. We tested this hypothesis using a cell culture system developed by mating BPK mice [bpk (+/-)], a murine model of ARPKD, with the Immorto-Mouse [H-2K(b)-ts-A58(+/+)]. Principal cell lines were isolated from the kidney collecting tubule segments from either cystic or non-cystic animals. Cells are grown in a chemically defined media on permeable filter inserts, which allows for polarization of the epithelial cells and domain-specific experiments. When looking at particular markers for EMT, we discovered that N-cadherin is overexpressed in the cystic cells. N-cadherin is a mesenchymal marker, typically induced during EMT. This overexpression was verified through both western blotting of cellular proteins and confocal microscopy. We have shown previously that the EGF receptor (EGFR) is found predominantly on the basolateral surface in normal cells, but is more evenly distributed on both apical and basolateral surfaces in cystic cells. Since the epithelial cell adhesion molecule E-cadherin is an important landmark for basolateral membrane cargoes, we hypothesize that overexpression of N-cadherin in the cystic cells is a contributing factor to EGFR mislocalization, which has been linked to hyperproliferation and cyst expansion and ARPKD.

546

**The Keratin-binding Domain of the γ-Turc Component GCP6 is Important for MTOC Localization and Architecture of Microtubules in Polarized Epithelial Cells**

A. S. Oriolo, F. A. Wald, P. J. Salas; Cell Biology and Anatomy, Univ. of Miami School of Medicine, Miami, FL

This work was intended to determine the molecular mechanisms that anchor γ-tubulin-containing structures to intermediate filaments (IFs), and to determine if apical non-centrosomal microtubule (MT) organizing centers (MTOCs) are important in the nucleation of MTs and stabilization of the *minus* ends in polarized epithelial cells. A screen of mammalian cDNA libraries by yeast-two hybrid showed that a 190 kDa component of the γ-tubulin ring complex (γ-Turc), GCP6, binds keratins. This finding was independently confirmed by expressing full-length HIS-tagged GCP6 and

using it in Far-Western analysis and pull-downs on purified keratins and IFs. Likewise, the same keratin-binding properties were shown for the C-terminal of GCP6 alone. Co-immunoprecipitation indicated that this is the same CDK1-responsive protein previously identified as a component of the MTOC/IF interphase. shRNA knock-down of GCP6 resulted in changes in the distribution of γ-tubulin, the architecture of MTs, and the localization of the MT nucleating activity in CACO-2 cells. Overexpression of the keratin-binding domain alone under the Tet-responsive promoter also resulted in redistribution of the γ-tubulin signal and basolateral nucleation of MTs. The HA-tagged GCP6 keratin-binding domain colocalized with IFs in vivo. MT nucleation experiments did not show any activity at the centrosomes, except in mitotic cells, but rather showed broadly distributed nucleation across the apical cortical region of CACO-2 cells, coincidental with the localization of non-centrosomal γ-tubulin in polarized cells. These results highlight the importance of IFs as a cortical scaffold for MTOC localization, shed light on the molecular mechanisms responsible for disorganization of MTs in K8 knock-out enterocytes, and are compatible with a model of MT nucleation at small non-centrosomal MTOCs in polarized epithelial cells.

**Role of the Crumbs Complex in the Morphogenesis and Homeostasis of Epithelia**

A. Le Bivic, M. Delgrossi, D. Michel, J. Arsanto, C. Beclin, D. Massey-Harroche; NMDA, IBDM, Marseille, France

Epithelial polarity is essential for the normal physiology of multicellular organisms since epithelia protect from the external environment and allow communication and exchanges with it. Control of cell polarity and proliferation in epithelial layers is also crucial for the homeostasis and shape determination preventing the development of polyps and tumors. Several protein complexes important for the development and the maintenance of epithelial cell polarity have been identified in the last years. Among these complexes, the Crumbs complex has a conserved role in the building and maintenance of epithelial apical junctions (Zonula Adherens in Drosophila and tight junctions (TJs) in mammals) acting coordinately with the PAR3/PAR6/aPKC complex. In mammalian epithelial cells, the Crumbs complex is made of Crb3, Pals1 and Patj and the exact contribution of each of these proteins in the mechanisms controlling epithelial homeostasis is not yet understood. We have used a human intestinal epithelial cell line, Caco2, as a model to understand the role of each member of the Crb3 complex by using a RNA interference strategy. We have studied in this work the impact of Patj knock down (KD) on cell polarity, TJ formation and proliferation in Caco2 cells. We have observed that several markers of TJs (Occludin and ZO-3) are mislocalized on the lateral membrane in Patj KD cells while Crb3 and Pals1 are re-distributed in intracellular compartments indicating that Patj acts as a linker between the Crb3 complex and the TJ. Moreover, we have found that Patj interact directly with the Tuberous Sclerosis complex that give multiple hamartomas when mutated in human. Patj acts as an regulator of the mTOR pathway through TSC and is thus the first component of the Crb complex involved in the control of tissue growth and homeostasis.

**aPKC/Par Proteins Show Asymmetric Localisation in Lens Epithelial Cells**

Y. Sugiyama,[1] A. R. Prescott,[2] R. A. Quinlan[1]; [1]School of Biological and Biomedical Sciences, Durham University, DURHAM, United Kingdom, [2]School of Life Sciences, University of Dundee, Dundee, United Kingdom

The eye lens comprises the anterior lens epithelial cells and its differentiated derivative, the lens fibre cells. Both cells have apico-basal polarity and cell polarity is expected to have important role for their physiological function and maintenance of cell shape. Since lens cell polarity is also maintained during lens development it suggests that is involved in lens formation as well. To analyse the role of cell polarity in the lens, we have tried to determine if aPKC/PAR machinery is responsible for lens cell polarity formation. aPKC/Par3/Par6 are major epithelial cell polarity proteins and the establishment of polarity is accompanied by their asymmetric localisation to the tight junction (TJ) region of epithelial cells. Using adult bovine lenses, we have found that aPKC/Par3/Par6 all locate asymmetrically at the apical cell contact region of lens epithelial cells. This region was also positive for the TJ proteins, ZO-1/occludin/claudin-1. The finding of expression of TJ specific proteins, occludin and claudin-1 in the lens was a somewhat surprising result as it has been previously reported that lens epithelial cells do not posses classical TJ structures. Furthermore, we detected the adherens junction (AJ) proteins, E-cadherin and N-cadherin, and a gap junction protein, Cx43, in the same apical cell contact region. The asymmetric localisation of aPKC/Par3/Par6 suggests this protein machinery is involved in establishing lens cell polarity. The finding that the apical cell contact region of the lens epithelial cell contains TJ, AJ and gap junction proteins simultaneously suggests lens epithelial cells develop atypical cell junction structure comparing to the typical epithelial cell junction. To clarify this particular junctional structure, we are now analysing it using immuno-electron microscopy. To indicate direct involvement of aPKC/PAR in lens development and analyse their roles, we have been developing mouse aPKC knockout lenses.

**Numb Controls Integrin Endocytosis for Directional Cell Migration with Par-3 and aPKC**

T. Nishimura, K. Kaibuchi; Cell Pharmacology, Nagoya University, Nagoya, Japan

Cell migration is characterized to extend a leading edge protrusion and to establish new adhesion sites at the front. Integrins are major cell adhesion receptors and play key roles in development, immune response, and cancer metastasis. Polarized membrane recycling including integrin is thought to be one of the driving forces for cell migration. However, molecular mechanisms for how integrins are internalized at the specialized cell area are largely unknown. We here found that endocytic protein Numb preferentially localized at the substratum-facing surface and polarized away toward the leading edge. Numb is a PTB domain containing adaptor protein implicated in clathrin-dependent endocytosis by binding to Eps15 and AP-2 complex. Numb bound to integrin-bs, and suppression of Numb inhibited integrin endocytosis, but not transferrin endocytosis. Correlated with the defects of integrin endocytosis, suppression of Numb impaired cell migration toward integrin substrates. Furthermore, Numb interacted with the polarity complex PAR-3 and was directly phosphorylated by aPKC. aPKC phosphorylation controlled the membrane localization of Numb, and thereby resulted in the defects of integrin endocytosis and integrin-stimulated cell migration. These observations suggest that Numb mediates integrin endocytosis at the substratum-facing surface for polarized cell migration, and that localization and functions of Numb are regulated by PAR-3 and aPKC.

### Chromogranin A Deficiency in Transgenic Mice Leads to Aberrant Chromaffin Granule Biogenesis

T. Kim,[1] C. Zhang,[1] Z. Sun,[2] H. Wu,[2] Y. P. Loh[1]; [1]NICHD, NIH, Bethesda, MD, [2]Peking University, Beijing, China

Dense-core secretory granules (DCGs) store and secrete neurotransmitters, hormones and neuropeptides in neuroendocrine and endocrine cells. In adrenal chromaffin cells, DCGs store and secrete catecholamines (CA), pro-enkephalin and chromogranin A (CgA) upon the stimulation by acetylcholine. Chromogranin A (CgA) is a highly abundant soluble glycoprotein present in DCGs. CgA binds CA for storage in the lumen of chromaffin granules, and it is co-released along with CA in a regulated manner. Recently CgA was shown to be a key regulator of DCG biogenesis at the trans-Golgi network in neuroendocrine PC12 cells (Kim et al., 2001 Cell 106:499-509). To study the role of CgA in DCG biogenesis *in vivo*, we generated transgenic mice expressing CgA antisense RNAs. CgA antisense transgenic mice showed significant reduction in CgA expression to 30-70% of wild type animals in adrenal glands. In addition, other granule proteins such as chromogranin B, carboxypeptidase E and dopamine β-hydroxylase were also decreased significantly in the adrenal of these mice. The reduction of CgA led to significant depletion (~30-50%) of DCG formation in adrenal chromaffin cells from these transgenic mice. The quantity of DCGs formed in the transgenic mice was directly correlated with the amount of CgA in adrenal medulla. Interestingly DCGs formed in transgenic mice were considerably enlarged in the luminal volume around the dense core, a phenomenon that occurs to maintain constant "free" CA concentration in the lumen of these granules. DCG swelling was correlated inversely with the quantity of DCGs formed in the adrenals, thus with the quantity of CgA in these mice. Our data indicate that CgA play an important physiological role in regulating chromaffin granule biogenesis and CA storage *in vivo.*

### The Effect of Somatostatin on the Release of $^3$H-1-methyl-4-phenylpyridinium from Bovine Adrenal Chromaffin Cells

L. Ribeiro, F. Martel, I. Azevedo; Biochemistry, Faculty of Medicine, Oporto, Portugal

Besides cholinergic regulation, catecholamine secretion from adrenal chromaffin cells can be elicited and/or modulated by noncholinergic neurotransmitters and hormones. This study was undertaken to investigate the influence of somatostatin on [$^3$H]MPP$^+$ secretion, evoked by KCl or cholinergic agents, from bovine adrenal chromaffin cells**.**The release of [$^3$H]MPP$^+$ from these cells was markedly increased by excess (50 mM) KCl (to 542±60 % of basal release, n=23). At concentrations between 50 μM and 10 mM, acetylcholine (ACH) significantly increased the release of [$^3$H]MPP$^+$ . The effect of ACH was concentration-dependent until 1 mM, where a maximal stimulation of 483±64 % over basal release was observed. However, the highest concentration of ACH (10 mM) induced a more modest increase than the previous dose (265±24 % over basal release). The acetylcholine-evoked release of [$^3$H]MPP$^+$ from these cells was mainly mediated by nicotinic receptors since: a) nicotine and 1,1-dimethyl-4-phenylpiperazinium (DMPP), selective nicotinic agonists, stimulated the release of [$^3$H]MPP$^+$, b) a nicotinic antagonist, hexamethonium, markedly blocked the acetylcholine-evoked response and c) pilocarpine, a muscarinic agonist, was devoid of effect on [$^3$H]MPP$^+$ secretion. At all concentrations tested, somatostatin and octreotide interfered neither with [$^3$H]MPP$^+$ basal release nor with KCl-induced release of [$^3$H]MPP$^+$. On the other hand, somatostatin (0.01-0.3 μM) increased the release of [$^3$H]MPP$^+$ induced by a high concentration (10 mM) of acetylcholine (to about a maximum of 210% over ACH-induced release) but, at higher doses (1 and 10 μM) was devoid of effect. Octreotide (1-10 μM) had no effect. These results support the hypothesis that somatostatin may increase the release of catecholamines from adrenal medullary cells.

### Control of Catecholamine Release from the Adrenal Medulla of $\alpha_{2a}$, $\alpha_{2b}$ and $\alpha_{2c}$ KO Mice

E. Moura, J. Afonso, H. de Sousa Lopes, M. A. Vieira-Coelho; Institute of Pharmacology and Therapeutics of Porto University, Porto, Portugal

$\alpha_2$-adrenoceptors have been reported (Brede et al, 2003) to inhibit adrenaline release from cultured adrenal chromaffin cells of mice. The aim of this work was to evaluate the effect of the $\alpha_2$-adrenoceptor agonist dexmedetomidine (MED) on catecholamine release from the adrenal medulla of knock out mice for each of the three $\alpha_2$-adrenoceptor subtypes: $\alpha_{2A}$, $\alpha_{2B}$ and $\alpha_{2C}$. Isolated adrenal medullae from control (CT) mice and $\alpha_{2A}$, $\alpha_{2B}$ and $\alpha_{2C}$ KO mice aged 30 weeks, were placed in suprafusion chambers and continuously washed with Krebs-Henseleit solution at a rate of 0.5mL.min$^{-1}$ for 90 minutes. Samples of suprafusion fluid were then collected every 5 minutes. Dimethylphenylpiperazinium (DMPP) (500μM) was added to the fluid for 5 minutes either in the absence or in the presence of MED (100nM). The assay of catecholamines in the tissues and in the fluid was carried out by HPLC-ED. Results are given as arithmetic mean±se. Statistical analysis was done by ANOVA. DMPP increased the release of NA and AD in all strains (CT: 4.59, 2.56; $\alpha_{2A}$: 4.18, 3.13; $\alpha_{2B}$: 3.30, 2.17; $\alpha_{2C}$: 4.66, 2.35 % increase in release, NA and AD respectively, n=5). The inhibitory effect of MED on NA induced release was similar between the KO mice strains (CT: 89; $\alpha_{2A}$: 33; $\alpha_{2B}$: 38; $\alpha_{2C}$: 36 %, n=5) whereas for AD induce release it was less marked for the $\alpha_{2C}$ KO mice (CT: 90; $\alpha_{2A}$: 54; $\alpha_{2B}$: 43; $\alpha_{2C}$: 29 %, n=5). In conclusion, although all three $\alpha_2$-adrenoceptor subtypes play a role in the regulation of the spontaneous release of NA and AD from the adrenal medulla of mice, the $\alpha_{2C}$ subtype might be the predominant subtype for AD release. ### Role of Alpha 1-adrenoceptor Subtypes in the Cardiac Failure Induced Sprague Dawley and Spontaneously Hypertensive Rats

S. Atif Abbas,[1] M. Zubaid,[2] M. N. Noriah[1]; [1]Faculty of Pharmacy, International Islamic University, Kuantan, Malaysia, [2]School of Pharmaceutical Sciences, Universiti Sains Malaysia, Penang, Malaysia

The function of kidney deteriorates during the development of cardiac failure because of changes in renal haemodynamics and neurohormonal activity. This study aimed to examine the alpha 1 adrenoceptor subtypes involved in mediating adrenergically induced renal vasoconstriction in a rat model of cardiac failure and hypertension. Normal Sprague Dawley (SD) and spontaneously hypertensive rats (SHR) were used in the study. Cardiac failure was induced by the combined treatment of caffeine (40mg/kg) and isoprenaline (5mg/kg) for seven days. On day eight, the rats were used for acute study. The left kidney was exposed, the renal artery cleared and an electromagnetic flow probe on it for renal blood flow (RBF) measurements. The reduction in renal blood flow induced by increasing frequencies of electrical renal nerve stimulation, close intrarenal bolus doses of noradrenaline, phenylephrine or methoxamine were determined before and after administration of amlodipine, 5-methylurapidil,

chloroethylclonidine and BMY 7378. Data, means ± s.e.m were compared with 2 way ANOVA followed by Bonferroni post hoc with the significance level of 5%. The results obtained indicated that the renal vasoconstrictor responses in this model were attenuated mainly by amlodipine, 5 methylurapidil and BMY7378 but not by chloroethylclonidine. Furthermore, administration of chloroethylclonidine did not show a significant reduction in methoxamine induced renal vasoconstriction in cardiac failure SD and SHR. This supported the view that alpha 1 A-adrenoceptors are involved in renal vasculature SD and SHR regardless of its pathophysiological state. The findings from this study further suggested that besides the alpha 1A the alpha 1D- adrenoceptors also contribute to the adrenergically induced renal vasoconstrictor responses in cardiac failure SD and SHR.

554

**Agonist Induced Internalization and Lipid Raft Trafficking of G alpha s Regulates Adenylyl Cyclase**

J. A. Allen,[1] J. Z. Yu,[1] A. Bhatnagar,[2] B. L. Roth,[2] M. M. Rasenick[1]; [1]Department of Physiology and Biophysics, University of Illinois at Chicago-College of Medicine, Chicago, IL, [2]Department of Biochemistry, Case Western Reserve University School of Medicine, Cleveland, OH

Many G protein-coupled receptors are internalized by endocytosis and recent studies have indicated that some G proteins also undergo agonist induced internalization. Previously, our laboratory has shown that stimulation of Beta-adrenergic receptors (BetaAR) results in lipid raft-mediated internalization of G alpha s (Gs). The objective of this current study is to determine whether agonist induced internalization of Gs from lipid rafts regulates cAMP synthesis. C6 glioma cells or C6 cells in which caveolin-1 was stably knocked down by RNAi (C6 Cav-1) were transfected with Gs-GFP and trafficking was assessed using fluorescence microscopy. Upon stimulation of C6 cells with the BetaAR agonist isoproterenol, Gs-GFP was rapidly removed from the plasma membrane and internalized within vesicles. However, Gs-GFP internalization was blocked by disrupting lipid rafts/caveolae with cyclodextrin and other cholesterol disrupting drugs. Subcellular fractionation studies revealed that agonist treatment significantly increased Gs localization in Triton X-100 insoluble lipid raft membrane fractions, while BetaARs were removed from lipid rafts. In addition, cyclodextrin disruption of rafts significantly increased isoproterenol and forskolin stimulated adenylyl cyclase activity. In experiments studying C6 Cav-1 cells, Gs-GFP did not internalize during agonist treatment, indicating that rafts/caveolae are necessary for Gs internalization. In addition, isoproterenol and forskolin stimulated adenylyl cyclase activity was significantly increased in the C6 Cav-1 cells vs. wild type C6 cells. These results suggest that during receptor activation, Gs is internalized through lipid raft/caveolae microdomains of the plasma membrane where it is less available to adenylyl cyclase, diminishing cAMP synthesis. We suggest that lipid rafts/caveolae act as negative regulators of BetaAR/Gs/adenylyl cyclase signaling.

**Trafficking of AMPA Receptors at Synapses is Regulated by LIN-10 and RAB-10**

D. R. Glodowski,[1] C. Chen,[2] B. D. Grant,[2] C. Rongo[1]; [1]Waksman Institute, Rutgers University, Piscataway, NJ, [2]Dept of Molecular Biology and Biochemistry, Rutgers University, Piscataway, NJ

In neurons, the regulated cycling of AMPA-type glutamate receptors (AMPARs) into and out of the synapse leads to changes in synaptic strength that are thought to be important for processes like learning and memory. We are using *C. elegans* to study AMPAR trafficking in an intact nervous system by visualizing localization of a chimeric protein containing the AMPAR subunit, GLR-1, fused to GFP (GLR-1::GFP). In the dendrites of wild-type animals, GLR-1::GFP is localized to discrete postsynaptic puncta. By contrast, mutants in *lin-10*, a Mint2 ortholog containing PTB and PDZ domains, accumulate GLR-1::GFP in large patches (1,2,3). In addition, *lin-10* mutants are deficient in their response to nose-touch mechanosensation, similar to *glr-1* mutant animals. To gain insight into the mechanism by which LIN-10 directs AMPAR trafficking, we used several genetic and cell biological approaches. First, using antibody labeling experiments that distinguish GLR-1 at the plasma membrane from intracellular GLR-1, we demonstrate that, in *lin-10* mutants, GLR-1 accumulates intracellularly. Second, by coexpressing GLR-1::GFP with RFP-tagged proteins that reside in distinct endosomal compartments, we show that excess GLR-1 accumulates in early endosomes in *lin-10* mutant animals. Third, we show that LIN-10 associates with these early endosomes, since GFP-tagged LIN-10 colocalizes with RFP::RAB-10, an early endosomal protein. Moreover, *rab-10* mutant animals display behavioral and GLR-1 localization phenotypes similar to those of *lin-10* mutants. Thus, we have identified RAB-10 as a novel regulator of AMPAR trafficking. Taken together, our data suggest that LIN-10 and RAB-10 function at synapses to mediate AMPAR trafficking out of early endosomes. (1) Rongo, C. et al. (1998) Cell: 94, 751-759. (2) Whitfield, C.W. et al. (1999) Mol Biol Cell: 10, 2087-2100. (3) Glodowski, D.R. et al. (2005) Mol Biol Cell: 16, 1417-1426.

**Role of Chaperone Proteins in KA2 Kainate Receptor Trafficking**

P. Vivithanaporn, G. T. Swanson; Pharmacology and Toxicology, University of Texas Medical Branch, Galveston, TX

Glutamate receptor trafficking is controlled by interactions between chaperone proteins and specific trafficking motifs within receptor carboxy terminal domains. We found recently that intracellular retention of the ionotropic glutamate receptor subunit KA2, a member of the kainate receptor subfamily, is caused by the association of coatomer protein complex I (COPI) with an arginine-rich domain in the KA2 cytoplasmic domain. In a variety of other integral proteins, COPI competes for binding with 14-3-3 family proteins, which appear to promote plasma membrane expression. Here we tested the hypothesis that 14-3-3 and COPI proteins together regulate kainate receptor trafficking through competitive interactions with the carboxy terminal domain of the receptor subunit. We initially determined if KA2 subunits and 14-3-3 proteins were associated in a macromolecular complex after transfection of COS-7 cells with myc-KA2 cDNA. Myc-KA2 was detected in Western blots with anti-myc antibody following immunoprecipitation of the 14-3-3ζ isoform from cell lysates. Mutation of retention/retrieval determinants in the KA2 c-terminus, R862-6 and L908-9, reduced the interaction of homomeric KA2 receptors with COPI by 67% but increased interaction with 14-3-3ζ by 4 fold (n = 5). Mutation of R862-6 alone also increased the association of the receptor subunit with transfected VSVG-14-3-3ζ by 2 fold (n = 3) and increased plasma membrane expression by 5 fold as determined by cell ELISAs. Thus, increased 14-3-3ζ association was correlated with reductions in COPI binding and higher cell surface expression of the receptor. Homomeric KA2 receptors also interact with the 14-3-3β isoform, while neither GluR5-2b nor GluR6a subunits had detectable level of interactions with COPI or 14-3-3ζ proteins. These results indicate that competitive interactions between chaperone proteins modulate kainate receptor trafficking and targeting, which in turn control the availability of receptors at the cell surface.

**Glutamate Expression is Reduced by Melatonin in Cortex, Hippocampus and Brainstem of Rats with Induced Endotoxic Shock**

E. López-Robles, E. Meza-Lamas; Immunology, Universidad Autónoma de Zacatecas, Zacatecas, Mexico

Bidirectional communication between the immune systems and brain allow a regulation in response to infections. The endotoxic shock is caused by lipopolysaccharides (LPS) of gram-negative bacteria, followed by overproduction of pro-inflammatory cytokines; after arriving to the central nervous system (CNS) such cytokines modify neuro-endocrine and immune functions and stimulates the overproduction of neurotransmitters like glutamate. Melatonin (MLT) is a neuro-immunomodulator which exerts protective effects in septic shock and inflammation. We studied the role of melatonin in the glutamate expression in cortex, hippocampus and brainstem of rats with endotoxic shock induced by LPS (*E. coli* 0111:B4). Melatonin was administered in a course time in relation to LPS administration. Sprague-Dawley adult males 10/group received intraperitoneal injection as follows: (i) Control, 500 µl of normal saline. (ii) Control-MLT, 10 mg/body weight of melatonin (500 µl ethanol:saline). In the next groups 3µg/body weight of MK-801 was applicated 30 minutes before of $DL_{100}$ LPS (iii) Single injection of $DL_{100}$ LPS. (iv) LPS+MLT, dose of LPS and dose of melatonin simultaneously. (v) LPS+MLT/30, dose of melatonin 30 min after LPS. (vi) LPS+MLT/60, dose of melatonin 60 min after LPS. Brains were obtained at 90, 150 and 270 min after LPS, then cortex, hippocampus and brainstem were dissected and homogenized in sulphosalcilyc acid at 5%, then analyzed and compared with standard of amino acid glutamate by HPLC. Our results show that bacterial LPS up-regulates the amino acid glutamate in cortex and brainstem, furthermore the melatonin significantly decreased these levels. In conclusion, melatonin significantly decrease the glutamate production, in consequence melatonin would regulate the manifestations of endotoxic shock in CNS.

**Vesicular Glutamate Transporter T3 is Modulated in the Basal Ganglia of a Rat Model of Parkinson's Disease**

K. K. L. Yung, E. K. Y. Chung; Biology, Hong Kong Baptist University, Hong Kong, Hong Kong Special Administrative Region of China

Parkinson's disease is a serious motor disorder in human and it is caused by a degeneration of dopaminergic neurons in the substantia nigra pars compacta. One effect after dopamine denervation is an overactivity of glutamate pathways in the brain. The transport of glutamate into synaptic vesicles is mediated by a group of vesicular glutamate transporters, namely the VGLUT1 and VGLUT2, which are characterized and found in most of the population of glutamatergic synapses. Recently, a third vesicular glutamate transporter VGLUT3 has been identified and it is structurally and functionally related to VGLUT1 and T2. VGLUT3 protein was found to be expressed in cholinergic, glutamatergic, GABAergic as well as dopaminergic neurons in the basal ganglia. VGLUT3 protein is then suggested to play a role in Parkinson's disease. The objectives of the present project were to study the changes of expression of VGLUT3 in an animal model of Parkinson's disease, the 6-hydroxydopamine-lesioned rat. By immunocytochemistry, VGLUT3 immunoreactivity was seen to reduce in perikarya of GABAergic neurons in the globus pallidus of the lesioned side. In contrast, in the subthalamic nucleus of the lesioned side, VGLUT3 immunoreactivity was found to be increased in perikarya of neurons. In the substantia nigra pars reticulata, a significance increase in VGLUT3 immunoreactivity was also observed in perikarya of GABAergic neurons. The expression of VGLUT3 by GABAergic, cholinergic and dopaminergic neurons in basal ganglia raises the possibility that glutamate may be co-released with other neurotransmitters. However, the physiological role of VGLUT3 in these cells is still not clear. The modulation of VGLUT3 expression in basal ganglia found in the present study suggests that VGLUT3 may be involved in the etiology and pathogenesis of Parkinson's disease. **Glutamate Receptor Subunit Expression in a Mouse Model of Tuberous Sclerosis**

K. Cordero,[1] D. M. Talos,[2] F. Jensen[2]; [1]Biology, University of Puerto Rico at Mayaguez, Mayaguez, PR, [2]Neurology, Harvard Medical School, Boston, MA

Tuberous sclerosis complex (TSC) is a disorder which manifests epilepsy and mental retardation. The tumor suppressor genes, TSC1 and TSC2, are inactivated in TSC patients. Previous experiments showed an alteration in glutamate receptor subunits in human cortical tubers of TSC patients. These alterations may be involved in the excitability and seizures in TSC patients. We hypothesized that human pathology of TSC is similar to the animal model of TSC pathology. This study consists in a mouse model with the *Tsc1* gene inactivated with the purpose of keep investigating the role of abnormal glutamatergic transmission in TSC-related seizures. Animals without the mutation were used as controls. The experiments focused in looking for the abnormalities in cortical tubers and the alterations on the glutamate receptor subunits. Mice brains were cut at 50µm. Immunofluorescence was performed in TSC tissues and normal tissues. This technique was used for staining glutamate receptor subunits; NMDAR subtypes ( NR1, NR2A and NR2B ) and AMPAR subtypes ( GluR 1-4 ), abnormal neurons and glial cells and the mutation activation marker pS6. Immunostaining of the neurons and glial cells showed the presence of abnormal large cells in the cortex and hippocampus in mutant animals. These cells displayed positive staining for pS6, GluR1, NR1 and NR2B. Immunostaining of normal neurons expressed low immunorectivity for pS6 and exhibited GluR2, NR1 and NR2A subunits in wild type animals. Abnormal and large cells resembled dysplastic neurons of human cortical tubers in mutant animals. These cells were positive stained for PS6 and expressed the AMPAR and NMDAR subunits, GLUR1 and NR2B respectively, for Ca2+ permeability. The results of the immunostainined *Tsc1* animal tissue were consistent with the TSC human tissue.

**Effects of PKC-delta Inhibitor Rottlerin on $Na^+/K^+$ -ATPase Activity in Rat Brain Tissue *in vitro***

K. T. D. Nguyen,[1] J. Shin,[1] T. Knight,[1] R. Clarke,[2] P. Else,[3] V. J. Balcar[4]; [1]Anatomy and Histology, School of Medical Science, University of Sydney, Australia, [2]School of Chemistry, University of Sydney, Sydney, Australia, [3]Department of Biomedical Science, University of Wollongong, New South Wales, Australia, [4]Anatomy and Histology, Institute for Biomedical Research, University of Sydney, Australia

Experiments using protein kinase C (PKC)-delta inhibitor rottlerin have suggested that L-glutamate transport (GluT) could be regulated by PKC-delta mediated phosphorylation. However, rottlerin has also been shown to influence GluT by an unknown PKC-independent mechanism. Using deconvolution microscopy and advanced computer-assisted image analysis we have found that rottlerin indeed blocked the substrate- (D-aspartate-) induced movement (without causing any movement/redistribution of GLAST in the absence of the substrates) of glutamate transporter GLAST into the membranes of astrocytes cultured from neonatal rat brain. We have hypothesised that rottlerin inhibits $Na^+/K^+$-ATPase that normally provides energy for GluT. We have earlier shown that rottlerin can act as an uncoupler of oxidative phosphorylation in brain slices and this may result in an

apparent "inhibition" of $Na^+/K^+$-ATPase activity. Indeed, rottlerin significantly inhibited of $Na^+/K^+$-ATPase activity in both brain slices and cultured brain astrocytes as determined by $Rb^+$ uptake ($Na^+/K^+$-ATPase handles $Rb^+$ about equally well as $K^+$; $Rb^+$ was estimated by atomic absorption spectroscopy). Could a direct effect of rottlerin on $Na^+/K^+$-ATPase contribute to the inhibition of $Rb^+$ uptake? $Na^+/K^+$-ATPase activity was estimated by measuring inorganic phosphate released by cell-free preparations of actrocytic membranes and, using isolated non-neural membranes, by a fluorescence technique (dye RH421). Both methods have indicated that rottlerin is a potent inhibitor of $Na^+/K^+$-ATPase. Surprisingly, ouabain was only a weak inhibitor of $Na^+/K^+$-ATPase in actrocytic membranes. This could explain why ouabain, an inhibitor of GluT in brain slices, is often less effective in cultures of glial cells: expression of the most closely GluT-related ("ouabain-sensitive") $Na^+/K^+$-ATPase may vary from one preparation to another, depending on the particular culturing conditions. Inhibition of glutamate transport by rottlerin can, however, be mediated by the direct inhibitory effect of rottlerin on $Na^+/K^+$-ATPase(s).

**Histochemical Localization of Activin Receptors IA, IB, IIA and IIB on Normal and Stroked Brain Tissue**

K. C. Lopez; Biology, University of Puerto Rico, Mayaguez, PR

A stroke is a blockage or rupture of an artery that results in a lack of oxygen and glucose to the brain and, thus, death of brain cells. Stroke is a leading cause of death and disability in the US for which few therapies are available. Preliminary data from others in this laboratory suggest that a ligand called activin is produced by nerve cells and that they may increase after a stroke. This ligand is being studied because it is believed that it can minimize the amount of cell death during a stroke. Strokes were induced in mice using transient middle cerebral occlusion (MCAO). The expression of activin receptors IA, IB, IIA, and IIB was assayed using immunohistochemistry techniques to study and compare the location of the receptors on stroked and normal brain tissues. These studies are designed to test the hypothesis that neurons have activin receptors and that the amount of activin receptors will increase in the surroundings of the stroked area. The technique used to stain the tissue showed that all of the receptors mentioned earlier are present in the cortex. The identity of the cells with activin receptors will be explored using double label fluorescence and cell type specific antibodies.

**The Distribution of M1 and M3 Muscarinic Receptors and CB1 Cannabinoid Receptors at the Lizard Neuromuscular Junction**

K. A. Lewin, A. R. Graves, C. A. Lindgren; Biology, Grinnell College, Grinnell, IA

The current study used immunofluorescence to localize M1 and M3 muscarinic acetylcholine receptors (mAChRs) and type 1 cannabinoid (CB1) receptors at the lizard neuromuscular junction (NMJ). Previous work in our laboratory has shown that the activation of M1 mAChRs facilitates neurotransmitter release, while stimulation of M3 mAChRs inhibits release via the activation of CB1 receptors. We report that (1) M1 mAChRs are located on motor nerve terminals, perisynaptic Schwann cells (PSCs), and muscles; (2) M3 mAChRs are located on PSCs and muscles; and (3) CB1 receptors are located on nerve terminals and PSCs. Activation of M1 receptors in any of the three synaptic compartments may enhance neurotransmitter release, although activation of presynaptic M1 mAChRs provides the simplest explanation of M1-mediated enhancement. As for the M3-mediated inhibition, we propose that activation of postsynaptic M3 mAChRs causes the retrograde release of endocannabinoids, and the activation of presynaptic CB1 receptors ultimately inhibits neurotransmitter release. Interestingly, all receptor subtypes examined in this study were located on PSCs, suggesting a potential role for these cells in the muscarinic modulation of neurotransmission at the lizard NMJ.

**Microsporidian Spore Walls Equipped with Extracellular Nicotinic Acetylcholine Receptor(nAChR)-Gated Channel Proteins**

E. Weidner; Biological Sciences, Louisiana State University, Baton Rouge, LA

Microsporidian spores of the genus Spraguea are common nerve parasites in fish of the genus Lophius. We reported earlier (Pleshinger and Weidner, 1985) that Sprageua spores activate with a calcium ion influx. This calcium influx requires preconditioning with shift in extrasporular pH to the alkaline in the presence of polyanionic mucin. Micromolar concentrations of calcium antagonists lanthanum or verapamil blocked spore activation and discharge. Here we report the presence of nAChR alpha proteins in the outer spore envelope of Spraguea. This was determined by specific nAChR antibodies using immunolabeling and Western blots. In addition, nAChR alpha units were identified by fluorescent bungarotoxin. High resolution imaging indicates nAChR proteins confine to linear rows in the outer envelope of the Spraguea spore wall. The gated channels of Spraguea activate by a sudden pH shift in the presence of activator mucin. In the natural environs, spores attach to mucous glands in the anglerfish cirri (lower jaw). The spores enter mucous cells and discharge near adjoining neuronal junctions. It is essential the spores inject invasive sporoplasm directly into tthe target neuronal fibers.The primary target cells are supramedullary neurons known to extend fibers to the skin and mucous glands. Current questions: how do the nAChR proteins operate in the spore wall and are these proteins of host or parasite origin?

**Altered High Affinity Choline Uptake in Primary Cortical Neurons from Presenilin-1 M146V Mutant Knock-in Mice**

Q. Guo, D. J. Payette, J. Xie; Department of Physiology, The University of Oklahoma Health Sciences Center, Oklahoma City, OK

The cholinergic neurotransmission plays a major role in regulation of many physiological functions. High affinity choline uptake is generally believed to be the rate-limiting step in acetylcholine synthesis in cholinergic neurons, and is essential for cholinergic transmission in the central nervous system. The high-affinity choline transporter-1 (CHT1) is a $Na^+$ and $Cl^-$-dependent, hemicholinium-3 (HC-3) sensitive choline transporter. Cholinergic hypofunction is associated with memory deficits in Alzheimer's disease (AD). Mutations in presenilin-1 (PS-1), which are causally linked to the pathogenesis of majority of familial AD cases, alter processing of the amyloid precursor protein (APP) in favor of production of the neurotoxic beta-amyloid peptide (Abeta), and increase neuronal vulnerability to apoptotic cell death. We previously found that pro-apoptotic proteins, such as Par-4, may alter CHT-1 mediated choline transport, resulting in a decreased choline uptake. We now report that high affinity choline uptake in primary cortical neurons from PS-1 M146V mutant knock-in mouse is significantly reduced compared to wild-type controls. Kinetic assays showed that the PS-1 mutation inhibited hemicholinium-3 (HC-3) sensitive choline uptake by reducing affinity of CHT1 to its substrate without significantly affecting the maximum levels of expression of CHT-1 in the plasma membrane. These results suggest that PS-1 mutations may contribute to the pathogenesis of dementia in AD by directly or indirectly affecting CHT-1 mediated choline uptake.

565

**EphB2 Receptor Signaling in Cultured Hippocampal Neurons involves Recruitment and Activation of FAK, Src, Paxillin, and RhoA**

M. L. Moeller,[1] Y. Shi,[1] L. F. Reichardt,[2] I. M. Ethell[1]; [1]Biomedical Sciences, University of California Riverside, Riverside, CA, [2]Physiology, University of California San Francisco, San Francisco, CA

The dendritic spines are the most common postsynaptic sites of excitatory synapses in the central nervous system and their formation is a critical aspect of synaptic development. The dendritic spine formation in hippocampal neurons is induced by synaptic contacts with presynaptic axon terminals and characterized by filopodia shortening and formation of mature mushroom-like spines, which accommodate the postsynaptic components of synapses. Defects in this process may underlie many neurodevelopmental disorders associated with mental retardation and autism. Previous studies by us and others have shown that interactions between EphB receptor tyrosine kinases and their cognate ligands, the ephrin-Bs, play a critical role in spine formation hippocampal neurons (Ethell et al., 2001; Penzes et al., 2003; Henkemeyer et al., 2003). Here we show a direct link between EphB receptor activation and intracellular signaling events associated with focal adhesion kinase (FAK). Activation of EphB2 receptors in cultured hippocampal neurons by ephrin-B2 results in the recruitment and assembly of a large, macromolecular protein complex resembling a focal adhesion complex (FAC). This complex includes FAK, Src, Grb2, and paxillin. Moreover, EphB2 activation leads to the additional activations of FAK, Src, and paxillin. Furthermore, the cre-mediated knockout of *loxP*-flanked *fak* or the siRNA-mediated disruption of FAK expression blocks EphB-mediated filopodia shortening. The results also show that EphB receptor activation induces RhoA activity suggesting that FAK/RhoGEF/RhoA mechanism might be responsible for the EphB-mediated shortening of dendritic filopodia. Based upon our current observations and past work, we speculate that downstream signaling events initiated by FAK might contribute to the EphB2-mediated formation of dendritic spines in hippocampal neurons. This work was supported by the NIMH grant MH67121.

**Axotrophin is Linked to LIF Signaling in the Nervous and Immune Systems**

G. E. Lyons,[1] M. A. Haendel,[1] P. A. D. Muthukumarana,[2] H. L. Thompson,[2] S. M. Metcalfe[2]; [1]Anatomy, University of Wisconsin Medical School, Madison, WI, [2]Surgery, University of Cambridge, Cambridge, United Kingdom

Axotrophin (axot) is highly conserved in mammals and the gene product has no clear homology with other proteins with the exception of a RING variant motif found in E3 ubiquitin ligase domains of the MARCH protein family. Discovered as a stem cell gene during gene trap mutagenesis screening, the axot null mouse revealed that axotrophin is involved in axonal regulation during formation of the corpus callosum in the brain and in the survival of unmyelinated C fibers of the substantia gelatinosa in the dorsal spinal cord. LIF mRNA levels are upregulated in the olfactory bulb and spinal cord of axot null mice. Unexpectedly, we found that axotrophin also plays a critical regulatory role in T lymphocyte responses, repressing proliferation (8-fold) and LIF release (5-fold). Analyses of isogenic T cell clones revealed phenotype-dependent effects, with Treg being associated with LIF release, in contrast to matched TH1 and TH2 effector T cell clones. In vivo, both axot and LIF expression were strongly associated with regulatory transplantation tolerance. This is the first evidence that LIF is regulated by axot and demonstrates new commonalities between embryonic stem cells and regulation of both the immune and nervous systems.

**Gonadotropin Receptor-Mediated Activation of G Protein-Activated Inwardly Rectifying $K^+$ (GIRK) Channels in Hypothalamic GnRH Neurons**

L. Hu, L. Z. Krsmanovic, K. J. Catt; Endocrinology and Reproduction Research Branch, National Institutes of Health, Bethesda, MD

Activation of luteinizing hormone (LH)/human chorionic gonadotropin (hCG) receptors in cultured hypothalamic cells and GT1-7 neurons transiently stimulates and subsequently inhibits cAMP production and pulsatile GnRH release. These changes were prevented by pertussis toxin (PTX), consistent with the coupling of LH/hCG receptors to adenylyl cyclase inhibitory G proteins. During LH treatment of both native and GT1-7 neurons, the frequency of spontaneous APs initially increased and progressively decreased during prolonged exposure. This inhibitory action of LH was also prevented by concomitant treatment with PTX, indicating that it is mediated by liberated $G_i/G_o$ subunits. Furthermore, GIRK1, 2, 3, and 4 channel subunits were found to be expressed in GT1-7 neurons. Whole-cell recording of GIRK current in normal and immortalized hypothalamic GnRH neurons was performed at 30 mM $K^+$ to increase current flow through GIRK channels, and channel activity was recorded as inward current at a holding potential ($V_H$) of -80 mV. The LH/hCG-induced currents were identified as GIRK currents based on their reversal potential of -30 mV, complete suppression by 200 μM $Ba^{2+}$, and inward rectification in the hyperpolarizing direction. During LH/hCG stimulation, maximum inward current was reached within 10-20 ms, followed by slow decay during prolonged stimulation. Pretreatment with PTX significantly reduced LH/hCG-induced GIRK current, indicating that this effect is mediated by liberated $G_i/G_o$ subunits. These data demonstrate that agonist-stimulated gonadotropin receptors in GnRH neurons activate GIRK channels, suppress membrane excitability, and slow spontaneous AP firing, leading to abolition of pulsatile GnRH release.

**Neuroglia Specific Expression of a FRET-based Calcium Indicator in Transgenic Mice**

S. D. Atkin,[1] L. A. Holtzclaw,[1] J. M. Pickel,[2] J. T. Russell[1]; [1]NICHD, NIH, Bethesda, MD, [2]NIMH, NIH, Bethesda, MD

Recent discoveries have highlighted the central role of glial cells in cellular signaling in the nervous system. Oligodendrocytes and Schwann cells receive signals during action potential traffic, and astrocytes monitor and modulate neural activity and plasticity. Such neuron-glial coordination relies on voltage and metabotropic calcium pathways and the mutual communications may play a vital role during development, maintenance of myelin, degeneration, and possibly regeneration of myelinated axons. We are interested in characterizing the calcium-based neuron-glial crosstalk in intact functioning brain tissue and peripheral nerve. One confounding problem is specifically labeling the glial cells of interest with appropriate $Ca^{2+}$ indicators such that physiological $Ca^{2+}$ signals can be recorded. We have developed transgenic mouse lines expressing the Cameleon (YC 3.60) $Ca^{2+}$ indicator protein under the control of a 9.6 kb human S100β glial-specific promoter. The promoter was fused upstream of the YC gene cassette. A sequence-verified clone of the plasmid was tested for cell specific expression by transfection and western analysis of C6 glioma and HEK cell cultures. Cellular $Ca^{2+}$ signals were measured in transfected C6 cells stimulated with 10μM ATP and up to a 90% increase in FRET was detectable. This construct was microinjected into C57Bl6/J embryos and founder mice and progeny were screened by PCR. Expression

characteristics were examined by immunohistochemistry using anti-GFP antibodies in 50µm brain sections from newborn pups. The transgene was expressed in 5 of 11 mouse lines. Expression is highly specific to astrocytes in the developing brain and CFP/YFP fluorescence is robust in two of the lines. Glial cell $Ca^{2+}$ signals associated with neural activity and axonal conduction can now be measured in the living animal, and these experiments are currently underway.

**Autoantibodies Associated with Lupic Psychosis Recognize a Novel Surface Protein and Induce Calcium Entry and Apoptosis in Brain Neurons**

S. Matus,[1] P. Burgos,[1] P. Farías,[2] O. Porras,[3] F. Torrealba,[2] F. Barros,[3] S. Jacobelli,[1] L. Massardo,[1] A. González[1]; [1]Depto. Reumatología. Fac. Medicina. Centro de Regulación Celular y Patología, Fac. Ciencias Biológicas. P. Universidad Católica de Chile, and MIFAB, Santiago, Chile, [2]Depto. Fisiología. Fac. Ciencias Biológicas. P. Universidad Católica de Chile, Santiago, Chile, [3]Centro de Estudios Científicos (CECS), Valdivia, Chile

More than fifteen years ago it was described that the psychosis of patients suffering from systemic lupus erythematosus (SLE) associates with autoantibodies against ribosomal P proteins (anti-P). This observation raised one of the most intriguing and controversial aspects in the pathogenesis of this prototypic autoimmune disorder. Anti-P autoantibodies recognize an epitope located in the carboxyterminus of three P ribosomal proteins, P0 (38 kDa) P1 (19 kDa) and P2 (17 kDa). In cells in vivo, intracellular antigens like ribosomal P proteins are normally inaccessible to circulating antibodies. There is evidence suggesting that these autoantibodies interact at the cell surface with a protein bearing the P-epitope. The antigenic target has not been identified but is currently believed it corresponds to the p38 ribosomal protein. The effect of these antibodies upon neuronal activity also remains completely unknown. We identify a novel transmembrane protein of high molecular mass (p>200) that exposes a ribosomal P epitope at the cell surface and is expressed exclusively by neurons at particular areas of the brain. Neurons in primary culture incubated with affinity purified anti-P autoantibodies rapidly increased their calcium levels and underwent apoptosis. Injection of anti-P antibodies into the brain also induced apoptosis in neurons. These results provide molecular and cellular bases supporting a pathogenic role of anti-P antibodies in neuropsychiatric lupus and open the possibility that dysfunctions of the p>200 protein might have pathogenic relevance in mental disorders in general. **Transcriptional Regulation of Murine Propionyl Coenzyme A Carboxylase Beta Subunit Production**

K. Motejlek,[1] M. Koker,[2] C. Borowski[2]; [1]Gynecological Endocrinology, University Hospital, Aachen, Germany, [2]Institute of Pharmacology, University Hospital Eppendorf, Hamburg, Germany

The function of propionyl coenzyme A carboxylase (PCC) which is found abundantly in mammalian mitochondria is the ATP-dependent conversion of propionyl CoA into D-methylmalonyl CoA. The enzyme is composed of six alpha as well as six beta subunits and mutations in both subunit types result eventually in propionic acidemia in humans. PCC deficient patients show elevated plasma levels of propionic acid and glycine accompanied by symptoms like developmental delay, generalized seizures, coma, and death. Treatment usually includes lifelong dietary protein restriction for the patients. To get a better understanding of the transcriptional regulation of PCC beta subunit production we identified a 390 bp sequence within the full-length PCCB cDNA by deletion analyses that showed an enhanced basal transcription level compared to controls. This cDNA fragment contains a regulatory element of 83 bp in length at its 5'-end which is rich in purines. By bandshift mobility assays a single-stranded DNA-binding protein complex was revealed that showed specific binding to the upper DNA strand in competition assays. The protein complex consists of two subunits with molecular weights of roughly 28 and 42 kDa. As seen in SDS-PAGEs it is very likely that two of the smaller subunits are associated with one 42 kDa subunit. The binding sequence, identified by methylation interference, covers 12 bp in total. The contact site within the enhancer box consists of two identical face-to-face motifs of 5 bp each with 2 bp in between. Whether this single-stranded DNA-binding protein complex is sufficient to regulate PCC beta subunit production by itself or if additional proteins are required has to be determined. Also, any temporal or tissue-specific glycosylation and phosphorylation of this protein complex has yet to be examined. Supported by the University of Hamburg, Germany

**Thread-to-grain Transition of Mitochondria Induced by Cytomegalovirus-encoded vMIA is Independent of Pro-apoptotic Bcl-2 Family Member, Bax**

K. L. Norris,[1,2] M. Karbowski,[1] B. Dlouhy,[1,3] R. J. Youle[1]; [1]SNB, NINDS, NIH, Bethesda, MD, [2]Institute of Biomedical Sciences, George Washington University, Washington, DC, [3]Howard Hughes Medical Institute-NIH Research Scholars Program, Bethesda, MD

The *UL37* gene of human cytomegalovirus (HCMV) encodes the viral mitochondria-localized inhibitor of apoptosis, vMIA, which functions to inhibit apoptotic cell death. Apoptosis inhibition is an important virulence factor of HCMV. vMIA is known to bind Bax, a pro-apoptotic Bcl-2 family member. Bax is located in the cytosol of healthy cells but translocates to mitochondria upon induction of apoptosis. Paradoxically, vMIA binding of Bax and inhibition of apoptosis also results in Bax translocation to mitochondria. In addition, vMIA expression causes changes in mitochondrial morphology. Mitochondria exist in healthy cells in dynamic, highly connected networks, but expression of vMIA results in fragmentation of mitochondria into small, punctate units. The vMIA protein has two domains that are necessary and sufficient for the inhibition of apoptosis, a mitochondrial targeting sequence and a Bax-binding region. Since Bax is known to cause mitochondrial fragmentation during apoptosis, we examined the role of Bax in the vMIA-induced mitochondrial morphology rearrangement. Interestingly, we found that expression of vMIA in mammalian cells lacking endogenous Bax still resulted in fragmentation of mitochondria. Expression of Bcl-xl, an anti-apoptotic Bcl-2 family member that neutralizes Bax, was unable to reverse the fragmented phenotype. Expression of vMIA mutants lacking the Bax-binding function also led to the fragmented phenotype, whereas targeting of vMIA to mitochondria was required for mitochondrial fragmentation. Based on these results, we conclude that Bax binding is not required for fragmentation of mitochondria by vMIA. Future studies will focus on the purpose of the Bax-binding function, as well as the mechanism by which vMIA alters mitochondrial morphology.

572

**Two Critical Factors Affecting the Release of Mitochondrial Cytochrome c as Revealed by Studies Using *N,N'*-Dicyclohexylcarbodiimide as an Inducer of Permeability Transition**

T. Yamamoto,[1,2] S. Terauchi,[1,2] A. Tachikawa,[1,2] K. Yamashita,[3] M. Kataoka,[1] H. Terada,[4] Y. Shinohara[1,2]; [1]Institute for Genome Research, University of Tokushima, Tokushima, Japan, [2]Faculty of Pharmaceutical Sciences, University of Tokushima, Tokushima, Japan, [3]School of Dentistry, University of Tokushima, Tokushima, Japan, [4]Faculty of Pharmaceutical Sciences, Tokyo University of Science, Noda, Japan

Mitochondrial permeability transition (PT) causes inner mitochondrial membrane to become highly permeable. When PT is induced, acceleration of mitochondrial oxygen consumption and swelling of mitochondria are commonly observed. PT also causes the release of cytochrome c (cyt.c) from mitochondria, and these proteins trigger the following processes of apoptosis. However, the relationship between induction of PT and release of cyt.c from mitochondria has not yet been fully understood. *N,N'*-dicyclohexylcarbodiimide (DCCD), a chemical generally used for formation of peptide bond, had been reported to show stimulatory effects on the mitochondrial oxygen consumption and to induce swelling of mitochondria. These data seemed to imply that DCCD caused PT, but this possibility had never been investigated. In this study, to understand the relationship between induction of PT and release of cyt.c from mitochondria, we examined effects of DCCD on the mitochondrial structure and function in detail. As a result, DCCD induced mitochondrial swelling insensitively for cyclosporine A, known as a specific inhibitor of ordinary PT. Further addition of polyethylene glycol (PEG) solution to preswollen mitochondria caused shrinkage of mitochondria, reflecting the increased permeability of inner mitochondrial membrane. These results clearly indicated that DCCD induced PT in a cyclosporine A-insensitive manner. However, unlike many other PT inducers, DCCD failed to cause massive release of cyt.c. To understand the relationship between induction of PT and release of cyt.c, actions of DCCD on mitochondrial structure and function were compared with those of $Ca^{2+}$, known as an ordinary PT inducer. In conclusion, two parameters of mitochondrial volume and rate of mitochondrial oxygen consumption were considered as critical parameters controlling the release of cyt.c.

573

**Induction of Permeability Transition in Yeast Mitochondria Causes Release of Mitochondrial Cytochrome c**

A. Yamada,[1,2] T. Yamamoto,[2,3] M. Kataoka,[2] T. Nagata,[1] H. Terada,[4] Y. Shinohara[2,3]; [1]School of Dentistry, University of Tokushima, Tokushima, Japan, [2]Institute for Genome Research, University of Tokushima, Tokushima, Japan, [3]Faculty of Pharmaceutical Sciences, University of Tokushima, Tokushima, Japan, [4]Faculty of Pharmaceutical Sciences, Tokyo University of Science, Noda, Japan

$Ca^{2+}$ is known to elevate the permeability of mitochondrial membrane of mammals, and this transition is referred to as the mitochondrial permeability transition (PT). When mitochondrial PT is induced, the changes of mitochondrial structure and functions such as acceleration of mitochondrial oxygen consumption, swelling of mitochondria, and dissipation of mitochondrial membrane potential are commonly observed. PT also causes the release of cytochrome c (cyt.c) from mitochondria, and these proteins trigger the following processes of apoptosis. However, the mechanisms of release of cyt.c from mitochondria and induction of PT have not yet been fully understood. To understand the mechanisms causing mitochondrial PT or release of mitochondrial cytochrome c, genetic approach using yeast cells is useful. Previously, it was reported that PT could also be induced in yeast mitochondria. However, the question whether the PT induced in yeast mitochondria is associated with the release of mitochondriral cytochrome c is still uncertain. To understand the relationship between release of mitochondrial cytochrome c and induction of mitochondrial PT, in the present study, we examined functional properties of yeast mitochondria. When PT was induced in mitochondria isolated from yeast cells, acceleration of mitochondrial oxygen consumption, swelling of mitochondria, and dissipation of mitochondrial membrane potential were observed. Furthermore, release of cyt.c from mitochondria was observed when PT was induced in mitochondria isolated from yeast cells. These findings indicate that PT induced in yeast mitochondria is also associated with release of cyt.c from mitochondria as well as PT induced in mammalian mitochondria.

574

**Structural Change of the Cytosolic Second Loop of Mitochondrial ADP/ATP Carrier Revealed by Cysteine-scanning Mutagenesis**

A. Iwahashi,[1,2] E. Majima,[3] H. Terada,[4] Y. Shinohara[1,2]; [1]Institute for Genome Reserch, University of Tokushima, Tokushima, Japan, [2]Faculty of Parmaceutical Scinences, University of Tokushima, Tokushima, Japan, [3]APRO Life Science, Naruto, Japan, [4]Faculty of Parmaceutical Scinences, Tokyo University of Science, Noda, Japan

ADP/ATP carrier (AAC) catalyzes the exchange of ADP and ATP across the mitochondrial inner membrane. Catalytic action of AAC is considered to be achieved by its interconversion between two distinct conformations, named c-state or m-state, in which substrate recognition site faces the cytosolic or matrix side, respectively. AAC is fixed into c-state or m-state by its specific inhibitors, carboxyatractyloside (CATR) or bongkrekic acid (BKA), respectively. Recently, crystal structure of bovine AAC complexed with CATR was reported. The revealed structure of AAC has six transmembrane segments connected by three and two loops facing to matrix and cytosol, respectively. However, it is still uncertain how AAC shows its catalytic activity on nucleotide exchange. To understand the catalytic mechanism of AAC, molecular characterizations of AAC at individual conformations are important. In the present study, to examine the structural properties of AAC at c- and m-state, we prepared various single-Cys yAAC2 mutants, having one particular Cys residue at the cytosolic second loop (LC2). These mutants were incubated with membrane-impermeable and fluorescent SH reagent, easin-5-maleimide (EMA), in the presence of CATR or BKA. By measuring reactivities of individual single-Cys yAAC2 mutant with EMA in c- and m-state, water-accessibility of Cys residue in LC2 was evaluated. As a result, conformation of LC2 changes between c- and m-state, suggesting that LC2 has important role as a gate.

575

**Intracellular Distribution of an Adenine Nucleotide Translocase in *Drosophila* Flight Muscles and the Challenge of Nucleotide Transport**

V. K. Vishnudas, S. S. Guillmette, J. O. Vigoreaux; Department of Biology, University of Vermont, Burlington, VT

Fast contracting muscles that experience high energy demands depend on diffusible ATP delivery mechanisms involving phosphagens. The *Drosophila* indirect flight muscles (IFM), however, do not appear to have a phosphagen based mechanism of ATP replenishment. Simple diffusion of nucleotides between the mitochondria (energy producer) and the myofibrils (energy consumer) is likely to maintain adequate ATP levels. In the myofibrils, ATP is hydrolyzed into ADP and Pi by myosin. Insect flight muscles are reported to exhibit high ATP flux (1000 μ mols $g^{-1}$ $m^{-1}$) during

flight. However the net flux of ADP by passive diffusion is low suggesting that other mechanisms may exists to facilitate the transport of ADP from myofibrils to mitochondria. Mass spectrometry analysis of *Drosophila* IFM skinned fibers revealed the presence of an adenine nucleotide translocase (ANT), encoded by the *stress sensitive B* (*sesB*) gene. Western blot analysis using an anti-bovine heart ANT antibody shows a single 32 kDa band in IFM skinned fiber samples. Immunofluorescence and quantitative immunoelectron microscopic studies suggest this ANT-like protein is associated with the myofibril. These results raise the possibility that an ANT shuttle system may be responsible for maintaining the flux of ATP and ADP into and out of the myofibrils. In order to address this possibility, we have made transgenic lines that express GFP tagged to the N terminus of two *sesB* cDNAs that differ in the length of their 3' Untranslated region (UTR). Mitochondrial proteins rely on cis elements in the 3' UTR of their mRNA for the correct localization of the mRNA and co translational import of the mature protein. The role of the different 3'UTRs in dictating the intracellular distribution of *sesB* is being examined by confocal microscopy.

576

**Function of StAR Signal Sequence is Controlled by its Pause**

M. Bose, D. Debnath, H. S. Bose; Department of Physiology and Funtional Genomic, University of Florida, Gainesville, FL

Steroidogenic acute regulatory protein (StAR), a 37kDa phosphoprotein, regulates steroidogenesis by facilitating cholesterol from the outer (OMM) to inner mitochondrial membrane (IMM). Mutant StAR cannot move cholesterol resulting in an inborn child disorder and fetuses die prematurely after birth. StAR, a 285-aminoacid protein, has a mitochondrial leader sequence, and cleaved to an intra mitochondrial 30kDa protein. To understand StAR's signaling process associated with its pause sequence, we hypothesized that deletion of its pause should increase its speed of entry into mitochondria and will not foster cholesterol movement, resulting no activity. Substitution of StAR leader (1-30 aa) or leader and pause together (1-62 aa) with mitochondrial matrix targeted protein, P450scc and its import into isolated mitochondria shows that StAR activity is proportional to its residency on the OMM. Signal sequence substituted StAR (Scc/N-30 StAR) imported slower than signal and pause (Scc/N-62 StAR) together. To characterize StAR-signaling mechanism in detail, we expressed Del-StAR (D31-62 aa) in E.coli, purified to homogeneity and characterized spectroscopically. Circular Dichroism analysis showed that Del-StAR is more a-helical at or below pH 4.5 and remains structured up to pH 1.0 without increasing coil. Partial proteolysis of Del-StAR with trypsin at pH 8.0 protected a band of 24 kDa, and with pepsin at pH 4.0 protected a ~5 kDa band. We found that partial proteolysis of biologically active N-62 StAR protected a 16 kDa band with Trypsin and Pepsin independently. Urea unfolding of Del-StAR at different pHs is 1.33 ±3 kcal/mol from pH 4.5 to 2.5, but it is 3.5 for N-62 StAR at pH 4.5 and no cooperativity of unfolding below pH 4.5. All these data suggest that the signal sequence changes StAR folding for its import.

**Comparison of Organellar Protein Profiles Between Hydrogen Peroxide Treated and Normal HeLa Cell Lines Using a Novel Technique for Separation and Enrichment of Organelles**

D. E. Kalman, J. A. Smith, H. Tran, W. Lan; Alfa Wassermann Proteomic Technologies, LLC, West Caldwell, NJ

Separation, fractionation and enrichment of subcellular components such as organelles is essential to study subcellular proteomes. Previously, differential and density gradient ultracentrifugation have been used to separate organelles. However, the efficiency and quality of these separation methods are limited by their batch mode and lengthy process time. In contrast to the traditional methods, we present a new technology: proteomics continuous-flow ultracentrifugation (pCFU$^{tm}$). pCFU provides a unique tool to separate and enrich organelles and organellar subtypes in one single and easy process. In this study, HeLa cells treated with hydrogen peroxide were compared to normal HeLa cell lines. Re-suspended cell pellets were dounce homogenized, followed by low-speed centrifugation to remove nuclei. pCFU was employed to further fractionate the supernatant and separate organelles by their buoyant density through a sucrose gradient. Mitochondria and ER enriched fractions were identified by Western blot analysis. To study the effects of hydrogen peroxide treatments on HeLa cells, the protein profiles of the organelle-enriched fractions from the treated cell lines were compared with those from normal HeLa cell lines using 2D gel electrophoresis and gel image analysis. Selected protein spots were digested with trypsin, and identified using nano-LC-ESI-MS/MS. Significant differences were observed between the protein profiles of the hydrogen peroxide treated HeLa cells and the normal HeLa cells. The results demonstrated that pCFU is a unique tool for fractionation, separation and enrichment of organelles and organellar sub-types. Consequently, pCFU technology in conjunction with 2D gel analysis significantly enhances subcellular proteomics studies.

**Mdv1 Interacts with Assembled Dnm1 to Trigger Mitochondrial Division**

K. Naylor,[1] V. Okreglak,[2] E. Ingerman,[1] J. E. Hinshaw,[3] J. Nunnari[1]; [1]Molecular and Cellular Biology, University of CA, Davis, Davis, CA, [2]Molecular and Cellular Biology, University of California, Berkeley, Berkeley, CA, [3]Laboratory of Cell Biochemistry and Biology, National Institutes of Health, NIDDK, Bethesda, MD

The dynamin-related GTPase, Dnm1, self-assembles into punctate structures that are targeted to the outer mitochondrial membrane where they mediate mitochondrial division. Post-targeting, Dnm1-dependent division is controlled by the actions of the WD repeat protein, Mdv1, and the mitochondrial TPR-like outer membrane protein, Fis1. Our previous studies suggest a model where at this step Mdv1 functions as an adaptor linking Fis1 with Dnm1. To gain insight into the exact role of the Fis1/Mdv1/Dnm1 complex in mitochondrial division, we performed a structure-function analysis of the Mdv1 adaptor. Our analysis indicates that dynamic interactions between Mdv1 and Dnm1 play a key role in division by regulating Dnm1 self-assembly.

**Mgr1p And Mgr3p Form a Substrate-Binding Subcomplex Within a Yeast Mitochondrial AAA-protease**

C. D. Dunn,[1] M. S. Lee,[2] F. A. Spencer,[3] R. E. Jensen[1]; [1]Cell Biology, Johns Hopkins School of Medicine, Baltimore, MD, [2]Genetics and Biology Center, National Heart, Lung, and Blood Institute, Bethesda, MD, [3]Institute of Genetic Medicine, Johns Hopkins School of Medicine, Baltimore, MD

Mutation or depletion of the mitochondrial genome is associated with several human diseases, including cancer, diabetes, myopathy, and neurodegeneration. In contrast to most other eukaryotes, the yeast *Saccharomyces cerevisiae* can live without mitochondrial DNA (mtDNA). To

identify the genes that allow for the growth of cells containing impaired mitochondria, we performed a microarray-based, genome-wide screen for yeast knockouts that can no longer tolerate mtDNA loss. Among the many candidates that we identified were two novel genes that we call *MGR1* and *MGR3* (Mitochondrial Genome Required). Both Mgr1p and Mgr3p are located in the mitochondrial inner membrane and associate with Yme1p, the catalytic subunit of the i-AAA protease complex. We find that Mgr1p and Mgr3p are required for efficient degradation of misfolded substrates, and both proteins form a subcomplex that can bind i-AAA substrates even in the absence of Yme1p. Our work highlights the requirement for robust quality control at the mitochondrial inner membrane in cells lacking mtDNA. Studies are underway to identify the key substrates of the i-AAA protease and to pinpoint the mechanisms by which Mgr1p and Mgr3p facilitate proteolysis by the i-AAA complex.

**Expression Pattern of OPA1 Protein Isoforms in *Mouse* Brain**

V. R. Akepati,[1] A. Otto,[2] E. C. Müller,[2] C. Alexander[1]; [1]Neurodegeneration, Max-Delbruck-Centre for Molecular Medicine, Berlin-Buch, Germany, [2]Neuroproteomics, Max-Delbruck-Centre for Molecular Medicine, Berlin-Buch, Germany

Autosomal dominant optic atrophy (ADOA) is the most common form of hereditary optic neuropathies. Mutations in the OPA1 gene encoding a dynamin-related mitochondrial protein underlie ADOA and may perturb the biogenesis and maintenance of the mitochondria. The OPA1 protein is localized to the mitochondrial intermembrane space, where it is tightly bound to the outer leaflet of the inner membrane. It has eight mRNA isoforms as a result of the alternative splicing of exons 4, 4b and 5b. In this study we investigated various mouse tissues for specific expression of different OPA1 protein isoforms and their involvement in complex formation. We raised monoclonal antibodies against OPA1 isoform 1, bacterially expressed as a GST fusion protein. Western blot analysis of mitochondrial lysates with anti-OPA1 monoclonal antibody identified five bands of OPA1 in heart, liver, kidney and brain migrating around 100kDa. Certain OPA1 isoforms presented with higher abundance then others within one given tissue. In addition, comparison of the band patterns of the used lyastes revealed tissue specific expression levels of various isoforms. Immunoprecipitation of OPA1 from mouse brain mitochondrial lysate, followed by tandem MS/MS mass spectrometry analysis identified that isoform 1 and 7 were predominantly expressed in brain. We applied glycerol density-gradient ultracentrifugation to investigate complex formations by these different isoforms. The results indicate that isoforms of OPA1 form the different molecular weight complexes ranging from 200kDa. In parallel, we performed a high-throughput Yeast two-hybrid screen for various proteins expressed in brain that pulled out FEZ-1 (Fasciculation and elongation protein Zeta), Vim (Vimentin) and Hip5 (Huntington interacting protein 5) as possible interacting partners. Isoform 1 of OPA1 is predominantly expressed in brain, which forms a different molecular weight complex. Whether these complexes are composed as homo-oligomer or hetero-oligomer is yet to be investigated.

**Studies of the Putative Twin Pore Structure of the Mitochondrial Protein Import Complex TIM23 and the Essential Role of Tim17p**

S. M. Grigoriev,[1] S. Martinez-Caballero,[1] J. M. Herrmann,[2] M. Campo,[3] K. W. Kinnally[1]; [1]Basic Sciense, New York University College of Dentistry, New York, NY, [2]Institut für Physiologische Chemie, Universität München, München, Germany, [3]Departamento de Bioquímica y Biología Molecular y Genética, Facultad de Veterinaria, Universidad de Extremadura, Cáceres, Spain

Most mitochondrial proteins are encoded by the nuclear genome. Import of matrix-bound proteins across the mitochondrial outer and inner membranes is mediated by two distinct translocases, the TOM complex and the TIM23 complex. The single channel behaviors of these complexes were investigated using patch-clamp techniques. The roles of the TIM23 complex components Tim23p, Tim17p, and Tim44p in protein import and channel properties were analyzed using knockdowns and other mutants. While mitochondria depleted of Tim44p fail to import preproteins, they can import short peptides and the electrophysiological properties of the Tim23 channels are not altered. Import of preproteins and translocation of signal peptides into mitochondria is eliminated by depletion of either Tim17p or Tim23p. Tim23 channel activity is abolished by depletion of Tim23p. Interestingly, depletion of Tim17p eliminates the putative twin pore structure and distinctive voltage gating of the Tim23 channel. Studies of the effects of *Tim17* mutations reveal the essential role of the N-terminus in incorporation of Tim17p into the pore of the Tim23 channel, putative twin pore structure and voltage gating. We found that trivalent cations ($La^{3+}$ and $Gd^{3+}$) reversibly block both Tim23 and Tom channels suggesting these cations may interact with the preprotein's binding site(s) of the channels. Trivalent cations are now being used to probe Tim23 channels with modified pores e.g., Tim17ΔN. These studies support the notion that Tim23 channels have twin pores whose size and symmetry are modified directly or indirectly by Tim17p. (This research was supported by NSF grant MCB-0235834 and NIH grant GM57249 to KWK.)

**The Mitochondrial Outer Membrane Protein hFis1 Regulates Mitochondrial Fission and Apoptosis**

T. Yu, Y. Yong; Department of Anesthesiology and of Pharmacology and Physiology, University of Rochester, Rochester, NY

Mitochondrial fission is mediated by a defined set of protein factors and is involved in the early stage of apoptosis. In mammals, two proteins, the dynamin-like protein DLP1/Drp1 and the mitochondrial outer membrane protein hFis1, have been identified to participate in mitochondrial fission. The cytosolic domain of hFis1 contains six α-helices that form two tetratricopeptide repeat (TPR) motifs. To define the role of hFis1, we generated truncated and mutated hFis1 proteins and assessed mitochondrial morphology and DLP1 binding properties. We found that overexpression of α1-deleted hFis1 (hFis1[32-152]) induced aberrant swelling of mitochondria, which was reduced by Bcl-2 overexpression and inhibitors of mitochondrial permeability transition. We also found that the mitochondrial swelling induced by hFis1[32-152] required DLP1 binding to TPR motifs and was caused by increased binding of DLP1 to mitochondria. The co-expression of Bcl-2 with hFis1[32-152] restored the amount of DLP1 in mitochondria to the normal level. Interestingly, overexpression of the dominant-negative mutant DLP1-K38A had little effect on mitochondrial swelling induced by hFis1[32-152] although it markedly reduced mitochondrial fragmentation induced by full-length hFis1, indicating that the hFis1-DLP1 interaction is independent of the DLP1 GTPase activity. Co-expression of Bcl-2 with full-length hFis1 did not affect the mitochondrial fragmentation, whereas Bcl-2 expression reduced the mitochondrial swelling by hFis1[32-152]. These data suggest that Bcl-2 is not directly involved in the DLP1/hFis1-mediated mitochondrial fission but possibly in the early interaction of hFis1 and DLP1 during DLP1 recruitment. Additionally, we found that most of the swollen mitochondria by hFis1[32-152] retained cytochrome *c* up to 72 hours post-transfection, resulting in significant delay of apoptosis. Our data suggest that hFis1 is a main regulator of mitochondrial fission, controlling the recruitment and assembly of DLP1 during both normal and apoptotic fission processes.

**Photophysics of DASPMI Stained Mitochondria in Living Cells**

R. Ramadass, J. Bereiter-Hahn; Kinematic Cell Research Group;Bio-center, Johann Wolfgang Goethe University, Frankfurt, Germany

The styryl dye 2-[4-(dimethylamino)styryl]-1-methylpyridinium iodide (DASPMI) is a low toxicity specific vital stain of mitochondria in living cells. Excitation and emission spectra, and quantum efficiency of DASPMI depend on solvent characteristics. Spectra of DASPMI stained mitochondria in living cells, correspond to those in a phospholipid environment (excitation around 470 nm, emission 560-570 nm). Fluorescence intensity of DASPMI is a dynamic measure for the membrane potential of mitochondria. In living cells, uptake of the dye is strongly influenced by uncouplers of oxidative phosphorylation such as CCCP (carbonylcyanide m-chlorophenylhydrazone). Photophysical properties of DASPMI were investigated using time- and space-correllated single photon counting technique. Spectrally and spatially resolved fluorescence decays of DASPMI stained mitochondria in living cells exposed to respiratory inhibitors are shown. Global analysis of the decays obtained showed a three exponential kinetics. The decay associated spectra of two of the three decay times were altered by different physiological conditions. These alterations on conditions reducing the mitochondrial membrane potential seem to be related to quenching processes (e.g. by energy transfer to oxidized cytochromes) and charge shifts in the mitochondrial membrane.

584

**Mitochondrial HDAC7 is Released from Inner Membrane Space Upon Apoptotic Insult**

R. E. Bakin, M. O. Jung; Radiation Medicine, Georgetown University Medical Center, Washington, DC

Control of global histone acetylation status is largely governed by the opposing enzymatic activities of histone acetyltransferases (HATs) and deacetylases (HDACs). HDACs were originally identified as modulators of nuclear histone acetylation status and have been linked to chromosomal condensation and subsequent gene repression. Accumulating evidence highlights HDAC modification of non-histone targets. Mitochondria were first characterized as intracellular organelles responsible for energy production through the coupling of oxidative phosphorylation to respiration. More recently, mitochondria have been implicated in programmed cell death whereby release of pro-apoptotic inner membrane space factors facilitates apoptotic progression. Here we describe the novel discovery that the nuclear encoded Class II human histone deacetylase HDAC7 localizes to the mitochondrial inner membrane space (IMS) of prostate epithelial cells and exhibits cytoplasmic relocalization in response to initiation of the apoptotic cascade. These results highlight a previously unrecognized link between HDACs, mitochondria, and programmed cell death.

**Aqp8 Water Channels and Mitochondrial Volume in Rat Liver**

G. Calamita,[1] D. Ferri,[2] P. Gena,[1] G. E. Liquori,[2] D. Thomas,[3] M. Svelto[1]; [1]Dept of General and Environmental Physiology, University of Bari, Bari, Italy, [2]Dept of Zoology, University of Bari, Bari, Italy, [3]UMR CNRS 6026, Rennes, France

Mitochondria are remarkably plastic organelles constantly changing their shape to fulfil their various functional activities. Although the osmotic movement of water into and out of the mitochondrion is central for its volume and activity, the molecular pathways for water transport across the inner mitochondrial membrane (IMM), the main barrier for molecules moving into and out of the organelle, are unknown. We recently reported an aquaporin water channel, AQP8, in rodent hepatocyte mitochondria (Ferri et al., Hepatology 2003; Calamita et al., JBC 2005). Here we employ immunoblotting, immunogold electron microscopy and stopped flow light scattering to investigate the correlations among mitochondrial AQP8 expression, mitochondrial morphology and water permeability. Both immunoblotting and immunogold electron microscopy localized AQP8 in the IMM of rat hepatocyte. The liver IMM was found to have a strikingly high coefficient of osmotic water permeability (Pf). Interestingly, the largest mitochondria featured the highest AQP8 expression and IMM Pf. AQP8 was also found in the mitochondria of other organs. The osmotic water transport of liver IMM was partially inhibited by the aquaporin blocker Hg2+, while the related activation energy remained low, suggesting the presence of a Hg2+-insensitive facilitated pathway in addition to AQP8. Overall, these results suggest that AQP8 facilitates the osmotic movement of water across the IMM. Moreover, the existence of an additional pathway other than aquaporins is postulated. AQP8 may be particularly important in the swelling which the mitochondrion undergoes following apoptotic stimuli and during oxidative phosphorylation. Recognition of AQP8 in mitochondria therefore has profound new implications for an understanding of how mitochondria adapt their volume.

**Dnm1, the Mitochondrial Division Dynamin, Forms Spirals that are Structurally Tailored to Fit Mitochondria**

E. Ingerman,[1] E. M. Perkins,[2] M. Marino,[3] J. A. Mears,[3] J. M. McCaffery,[2] J. Nunnari[1]; [1]Molecular and Cellular Biology, UC Davis, Davis, CA, [2]Department of Biology and Integrated Imaging Center, Johns Hopkins University, Baltimore, MD, [3]Laboratory of Cell Biochemistry and Biology, NIDDK, NIH, Bethesda, MD

Dynamin-related proteins (DRPs) are large, self-assembling GTPases whose common function is to regulate membrane dynamics in a variety of cellular processes. Dnm1, a yeast DRP (Drp1/Dlp1 in humans), is required for mitochondrial division, but its mechanism is unknown. Using a variety of biochemical techniques, we identified two novel regulatory features of Dnm1. Dnm1 self-assembly proceeded through a rate-limiting nucleation step and nucleotide hydrolysis by assembled Dnm1 structures was highly cooperative, with respect to GTP concentration. As seen by electron microscopy, Dnm1 formed extended spirals, which possessed diameters greater than those of the prototypic DRP, dynamin-1. The diameters of the Dnm1 spirals, remarkably, were equal to those of *in vivo* mitochondrial constriction sites, which we visualized by electron microscopy in thin sections of yeast cells. Thus, our data support a model in which nucleation-dependent self-assembly of Dnm1 into spirals drives the constriction of the outer and inner mitochondrial membranes during mitochondrial fission. Our data further suggest that Dnm1 has evolved to form structures that fit the dimensions of mitochondria.

**A Mitochondrial DNA Analysis of the Major Ethnic Groups in Sierra Leone and Cameroon**

J. L. Wilson,[1] B. Ely,[2] B. A. Jackson[3]; [1]Department of Chemistry, University of Massachusetts Lowell, Lowell, MA, [2]Department of Biological Sciences, University of South Carolina, Columbia, SC, [3]Biomedical Engineering and Biotechnology Program, Department of Work Environment,

University of Massachusetts Lowell, Lowell, MA

Previous studies of African human mitochondrial DNA (mtDNA) have focused primarily on discerning the origins of modern humans and the worldwide expansion of human populations. These same studies have demonstrated that Africa contains the greatest level of mtDNA diversity in the world (Ingman et al., 2000). However, there has been no published study to characterize genetic differences in the mtDNA of the many ethnic groups of Africa that were the sources of slaves for the Americas and Caribbean. Such a study would be important to blacks of these regions whose African heritage was lost due to slavery. The hypervariable one region of mtDNA from 276 individuals from Sierra Leone and 650 individuals from Cameroon of various ethnic groups were sequenced and haplogroups determined. An analysis of molecular variance indicated that the distribution of these haplotypes within certain ethnic groups was significantly different from that of the other ethnic groups. The results of this study indicate that distinguishing genetic differences can be observed among African ethnic groups residing in historically close proximity to one another (Jackson et al., 2005). Furthermore, it was observed that some mtDNA haplotypes are common among the Sierra Leone and Cameroonian ethnic groups, but have not been observed in other published studies of West African ethnic groups. Therefore, this may be the first genetic evidence for mtDNA lineages that are unique to these regions of West Africa.

### Analysis of *Gregarines niphandrodes* Extranuclear DNA

M. Toso, C. K. Omoto; School of Biological Sciences, Washington State University, Pullman, WA

We investigated whether or not gregarines possess extranuclear DNA and if so, their identity. Gregarines are understudied unicellular parasites of invertebrates in the phylum Apicomplexa. Many apicomplexa possess two types of extranuclear DNA, mitochondrial and plastid. The non-photosynthetic plastids for a number of apicomplexans (*Plasmodium, Toxoplasma, Babesia, Eimeria, Theileria*) contain 35kb circular genome. The apicomplexan mitochondrial genome is unusual in being small, 6kb, and linear. It encodes two proteins: cytochrome C and cytochrome B and small fragments of rRNA gene. Whole genome sequencing of one genus of apicomplexa, *Cryptosporidium*, shows that it lacks both the plastid and mitochondrial genomes. Phylogenetic analyses using both 18S ribosomal RNA gene, and DNA-dependent RNA polymerase, largest subunit (RPB1) indicates that gregarines and *Cryptosporidium* are closely related. This relationship raises the question, "Do gregarines possess extranuclear DNA?" 4',6-Diamidino-2-phenylindole (DAPI) staining of *Gregarina niphandrodes* trophozoites shows extranuclear punctate staining. PCR using plastid-specific primers that amplified LSU rRNA and *tufA*-tRNA sequences from *Plasmodium falciparum* and *Toxoplasma gondii* did not produce any amplicons with *Gregarina niphandrodes* DNA. We did not observe an organelle with plastid ultrastructure in transmission electron microscopy of *Gregarina niphandrodes* trophozoites, yet mitochondria were observed. Using primers for the mitochondrial cytochrome C gene, we have retrieved a partial sequence of the gene from *Gregarina niphandrodes*. Phylogenetic analysis of this sequence indicates that it is a member of the apicomplexan mitochondrial cytochrome C gene family. Therefore, we conclude that *Gregarina niphandrodes* does not possess either a plastid organelle or a plastid genome. However, *Gregarina niphandrodes* possesses extranuclear DNA and it is mitochondrial. We are currently completing the sequencing of this mitochondrial genome.

589

### Regulation of Mitochondrial Morphology by Intracellular $Ca^{2+}$

J. R. Hom,[1] S. Sheu,[1] Y. Yoon[2]; [1]Pharmacology and Physiology, University of Rochester Medical Center, Rochester, NY, [2]Anesthesiology, University of Rochester Medical Center, Rochester, NY

Mitochondria are dynamic organelles that frequently change shape and location within the cell. This dynamic behavior is mediated by defined sets of factors, including proteins involved in fission, fusion and translocation of mitochondria. While many protein factors directly participating in mitochondrial dynamics have been identified, upstream signals that regulate mitochondrial morphology are not understood. In this study, we tested the role of intracellular $Ca^{2+}$ in regulating mitochondrial morphology. We found that mitochondria underwent two phases of fragmentation upon exposure to the ER $Ca^{2+}$-ATPase inhibitor thapsigargin (TG). The initial fragmentation of mitochondria was a transient event, as mitochondria became rapidly fragmented within 10 minutes following the cytosolic $Ca^{2+}$ transient and tubular mitochondria were restored in an hour after cytosolic $Ca^{2+}$ decreased to the resting level. We found that the initial fragmentation of mitochondria is $Ca^{2+}$ concentration-dependent, suggesting that it is likely mediated by cytosolic $Ca^{2+}$ signaling. In addition, inhibition of the mitochondrial fission protein DLP1 blocked the fragmentation, indicating that TG-induced mitochondrial fragmentation occurred via mitochondrial fission process. Furthermore, inhibition of hFis1, the upstream DLP1 recruiting protein, also prevented the TG-induced mitochondrial fragmentation, suggesting that increased cytosolic $Ca^{2+}$ acts at the early stage to activate cellular mitochondrial fission machinery. We also found that prolonged incubation with TG caused non-reversible apoptosis-associated mitochondrial fragmentation. In contrast to the initial fragmentation, the second phase mitochondrial fragmentation occurred regardless of TG-induced cytosolic $Ca^{2+}$ increase, suggesting that sustained TG treatment caused ER stress-mediated apoptosis through ER $Ca^{2+}$ depletion. We also identified a potential role of DLP1 in mitochondrial outer membrane permeabilization that leads to cytochrome *c* release in the absence of mitochondrial fission during TG treatment. Our data demonstrate that $Ca^{2+}$ participates in controlling mitochondrial morphology via intracellular $Ca^{2+}$ signaling as well as apoptosis-related process.

590

### The Opa1 (optic Atrophy 1) Gene Is Essential for Embryonic Development in the Mouse

M. Fiket,[1] M. Seeliger,[2] C. Alexander[1]; [1]Neurodegeneration, Max-Delbrueck-Center for Molecular Medicine, Berlin-Buch, Germany, [2]Retinal Electrodiagnostics Research Group, Dept. of Pathophysiology of Vision and Neuroophthalmology, University Eye Hospital, Tuebingen, Germany

*OPA1* is a nuclear gene encoding a large mitochondrial dynamin-related GTPase implicated in mitochondrial fusion and maintenance. Mutations affecting the coding region of *OPA1* result in the clinical phenotype of autosomal dominant optic atrophy (adOA), which leads to visual loss in humans and retinal ganglion cell death. We sought to generate a mouse model allowing us to analyse OPA1 function in vivo. Most of the disease causing mutations in adOA patients result in haploinsufficiency. Therefore, we disrupted exon 2 of the mouse *OPA1* gene by introducing a Neomycin cassette at the exon/intron border. Our targeting strategy completely abolished functional gene expression from this *mOPA1* allele, theoretically resulting in a dosage effect in heterozygous animals, and loss of function in homozygous m*OPA1*-knock-out mice. Heterozygous mice are viable and fertile. We have examined eyes and optic nerves of such mice at different stages of postnatal development. Plastic sections of retinae

and optic nerves were stained with cresyl violet. Electroretionography (ERG) and scanning laser ophthalmoscopy (SLO) were performed in order to test for functionality of various retinal cell types and retinal ganglion cell properties. Unfortunatelly, we could not detect phenotypic changes in the visual system between *mOPA1*-deficient and wildtype mice. Homozygous mutants are embryonic lethal and die between e7.5 and e8.5. We conclude that, in contrast to humans, mice seem to be able to compensate for the loss of a functional *mOPA1* gene copy. On the other hand, embryonic lethality of homozygous mutants reveals that humans, as well as mice , greatly depend on OPA1 function. Further examination of those very early dying embryos will allow us to understand this unexpectedly harsh phenotype and the essential involvement of OPA1 in mitochondrial function.

591

### Targeting Of Rice Glycoprotein Alpha-amylase I-1 Into Plastid: Plastid Targeting Signal

T. Mitsui,[1,2] S. Asatsuma,[3] C. Sawada,[3] A. Kitajima[3]; [1]Dept. Applied Biol. Chem., Niigata University, Niigata, Japan, [2]Lab. Plant Microbial Genome Control, Niigata Univ., Niigata, Japan, [3]Lab. Plant Microbial Genome Control, Niigata University, Niigata, Japan

Previous our study has shown that alpha-amylase I-1 is involved in degradation of plastidial starch in rice living cells (Plant Cell Physiol. 46:858-869, 2005). In the present study, we performed transient expression and targeting of rice alpha-amylase I-1 fused with green fluorescence protein (GFP) in onion epidermal cells. It was found that alpha-amylase I-1-GFP fusion protein targets into the plastids visualized with the plastidial marker WxTP-DsRed in bombarded onion cells. In contrast, the other alpha-amylase isoforms (II-4, II-5, and II-6) did not localize in the plastids. These results indicate that rice alpha-amylase I-1 contains a plastid targeting signal common to both monocotyledonous rice and onion cells. To determine an important region for the plastidial targeting of alpha-amylase I-1, transient expression and localization of a series of carboxy-terminal truncated native alpha-amylase I-1-GFP fusion protein was tested. The results showed that the peptide region from 301 to 369 amino acid residues including a putative starch binding site is important for plastid targeting of alpha-amylase I-1 in onion cells. We further examined the targeting characteristics of the starch binding site-mutated alpha-amylase I-1-GFP fusion protein in onion cells. The Typ301-Typ302 was a unique amino acid residues in the polypeptide of alpha-amylase I-1, while the other alpha-amylase isoforms, such as II-4, II-5, and II-6, had no the tryptophan dipeptide in this area. The substitution of Ala302 for Typ302 strongly arrested the targeting of alpha-amylase I-1-GFP into the plastids. Based on these overall results, we concluded that the Typ302 residue is necessary for the plastid targeting of alpha-amylase I-1 in onion epidermal cell.

592

### The Outer Envelope of Plant Plastids Functions as Selective Permeability Barrier for Solutes During Plant Development

K. Philippar, A. Timper, R. Thomson, J. Soll; Department for Biology I, Botany, Ludwig-Maximilians-University of Munich, Munich, Germany

Plastids of higher plants originate from the endosymbiosis of a cyanobacterium with an early eukaryotic cell. In the green organs of plants this leads to the evolution of chloroplasts, representing the site of photosynthesis. However, chloroplasts are only one member of the organelle family called plastids. Besides photosynthesis, plastids conduct specialised functions that are essential for plant growth and development (e.g. nitrogen assimilation, storage of carbohydrates and lipids, synthesis of amino acids, fatty acids and secondary compounds). Because of this fundamental biosynthetic capacity, function of the plant cell requires the exchange of metabolites between plastids and the surrounding cytosol. As their Gram-negative ancestors, plastids are delimited by two membranes, the outer and inner envelope. Communication in this integrated metabolic network is thus mediated by transport proteins in the envelope membranes. Due to the presence of porins, the outer envelope has been assumed to be a size-selective sieve only, whereas the inner envelope has been considered to be the actual permeability barrier. However, several channel-like proteins, exhibiting substrate specificity and characteristic gating properties could be isolated from chloroplastic outer envelopes of pea. To prove the concept of a regulated gate in the outer envelope of plastids, we characterized mutants of OEPs ("outer envelope proteins") in the genetic model plant *Arabidopsis thaliana.* Here the OEP24 family shows specific expression pattern in developing seeds and pollen. While a T-DNA insertion mutant of *OEP24.1* is homozygous-lethal and impaired in pollen germination, expression of *OEP24.2* is high in late stages of seed development and in germinating seeds. Therefore, OEP24.1 functions as an essential and selective transport barrier in the outer envelope of plastids, supplying solutes for early pollen development. In contrast, OEP24.2 operates in the storage-type plastid of seeds.

### Syntabulin-Mediated Anterograde Transport of Mitochondria Along Neuronal Processes

Q. Cai, Z. Sheng; Synaptic Function Unit, National Institute of Neurological Disorders and Stroke, National Institute of Health, Bethesda, MD

In neurons, proper distribution of mitochondria in axons and at synapses is critical for neurotransmission, synaptic plasticity, and axonal outgrowth. However, mechanisms underlying mitochondrial trafficking throughout the long neuronal processes have remained elusive. Syntabulin is originally identified by our lab and implicated in the syntaxin-1 transport in neurons (Nat. Cell Biol. 2004, 6:941-953). Here, we report that syntabulin plays a critical role in mitochondrial trafficking in neurons. Syntabulin is a peripheral membrane-associated protein which targets to mitochondria through its carboxyl terminal tail. Using real-time imaging in living cultured hippocampal neurons, we demonstrate that a significant fraction of syntabulin co-localizes and co-migrates with mitochondria along neuronal processes. Knockdown of syntabulin expression with targeted siRNA or interference with the syntabulin-kinesin-1 heavy chain interaction with dominant negative transgenes reduces mitochondrial density within axonal processes by impairing anterograde movement of mitochondria. These findings collectively suggest that syntabulin acts as a linker molecule capable of attaching mitochondrial organelles to the microtubule-based motor kinesin-1, and in turn, contributes to anterograde trafficking of mitochondria to the neuronal processes.

## Endoplasmic Reticulum (594-615)

594

### Regulation of the Unfolded Protein Response by Small GTP Binding Proteins in Celegans

M. Caruso,[1] S. Jenna,[1] M. Vidal,[2] D. Baillie,[3] E. Chevet[1]; [1]McGill University, Montreal, PQ, Canada, [2]Harvard Medical School, Boston, MA, [3]Simon Fraser University, Vancouver, BC, Canada

The Unfolded Protein Response (UPR) is a conserved adaptive mechanism activated in eukaryotic cells subjected to physiological stresses. It is

caused by the accumulation of mis/unfolded proteins in the endoplasmic reticulum (ER) which in turn promote the activation of ER resident sensors and their downstream signaling cascade. This leads to three major outcomes including translation inhibition, activation of the SAPK/MAPK pathway and activation of specific transcriptional programs. In an attempt to characterize novel regulators of the UPR, we have developed a systematic gene silencing approach with *Caenorhabditis elegans* as a model system. Our efforts have at first focused on small GTP binding proteins which are key regulators of the exocytic, endocytic and signal transduction pathways. Therefore, we postulated that an alteration of the expression of these GTPases could impact on the UPR in *C.elegans*. To visualize this phenomenon, we are studying twelve *C.elegans* GFP reporter strains for genes whose expression is potentially UPR-regulated in the worm. We observed that most of these reporters show variable level of expression but are mainly expressed in the intestine under basal conditions. When exposed to the ER stressor tunicamycin, five strains showed a significant increase in GFP expression at both qualitative and quantitative levels. Consequently, from the 60 GTPases encoding genes identified in *C.elegans* genome, we selected only those for which the expression product localized in the intestine and co-localized with compartment markers of the secretory pathway. This strategy resulted in the selection of only one third of the initial GTPase population. These selected targets are systematically silenced in the five reporter strains in the presence or absence of tunicamycin. Preliminary observations revealed that the Rab family of GTPases may represent a novel complex regulator of the Unfolded Protein Response.

**Xbp-1(s) Contributes to Ig Heavy Chain Expression at Both Transcriptional and Post-transcriptional Levels in a Plasmacytoma Cell Line**

Y. Shen,[1] Y. Jin,[1,2] L. M. Hendershot[1,2]; [1]Department of Genetics and Tumor Cell Biology, St. Jude Children's Research Hospital, Memphis, TN, [2]Department of Molecular Sciences, University of Tennessee, Health Science Center, Memphis, TN

ERdj3/HEDJ is a component of unassembled immunoglobulin heavy chain (HC):BiP multi-chaperone complexes and is highly expressed in HC only plasmacytoma cell lines as compared to $Ig^-$ cell lines. Recently ERdj3 was shown to be a target of the XBP-1 transcription factor, which is induced (via ATF6) and spliced (via Ire1) during UPR activation. The spliced form of XBP-1 is required for plasma cell differentiation, thus raising the possibility that XBP-1 contributes to HC stability in plasma cells. In this study, we demonstrate that although XBP-1 is responsible for the up-regulation of ERdj3 during ER stress, it did not control basal expression of ERdj3 under normal physiological conditions in non-lymphoid cells. Thus, we wished to determine if XBP-1(S) contributed to high steady state ERdj3 levels in HC only cells or if instead this represented an increased basal expression of ERdj3. We found that XBP-1(S) was highly expressed in plasmacytoma cells that produce unassembled HCs, indicating that the UPR remains active in a stable plasmacytoma line. When XBP-1 expression was knocked down in the plasmacytoma cells, the expression of *ERdj3* was modestly compromised. Surprisingly, the transcription of BiP was reduced as well both in the absence and presence of the HC. This indicates that XBP-1(S) contributes to the expression of ERdj3 and BiP in plasma cells, and that this regulation is independent of antibody production. Expression of HC was also diminished, but unexpectedly this occurred at the transcriptional level. Our data revealed that XBP-1(S) positively regulated the HC enhancer gene OBF1/BOB1, thus serving to increase HC expression at the transcriptional level.

**The C-Terminal Domain of Calreticulin (CRT) Mediates Retrotranslocation to the Cytoplasm Independently of ER-associated degradation**

N. Afshar,[1] B. E. Black,[2] B. M. Paschal[1]; [1]Center for Cell Signaling, University of Virginia, Charlottesville, VA, [2]University of California, San Diego, San Diego, CA

CRT is a calcium-binding chaperone that undergoes synthesis at the endoplasmic reticulum (ER). However, CRT has been implicated in multiple nuclear and cytoplasmic processes, including cell adhesion, RNA binding, transcriptional regulation, and nuclear transport. In contrast to the dogma that CRT influences these processes from within the ER lumen, we have advanced the alternative view that CRT plays a direct role in these processes by undergoing retrotranslocation to the cytoplasm. We previously used a battery of assays to show that CRT retrotranslocates out of the ER lumen (MCB in press). Here we determine the domain of CRT that mediates retrotranslocation. We targeted an artificial transcription factor (ERX) to the ER lumen with an N-terminal signal sequence. Fusing CRT to ERX enables the transcription factor to escape the ER lumen, and, subsequently, enter the nucleus where it activates a luciferase-based reporter plasmid. Retrotranslocation activity was mapped to the C-terminal region of CRT, which was both necessary and sufficient for retrotranslocation. The latter conclusion was based on the ability of the CRT C-domain to mediate retrotranslocation of PDI. To date, retrotranslocation has been associated with ER-associated degradation of misfolded proteins. CRT retrotranslocation, however, is not dependent on proteasome activity, nor does it involve ubiquitylation. As CRT has been implicated in cell adhesion through its interaction with integrins, we examined the adhesion and motility properties of *crt-/-* mouse embryonic fibroblasts (MEFs). *crt-/-* MEFs were reduced in cell migration two-fold relative to WT MEFs. *crt-/-* MEFs also displayed reduced binding to collagen, which was rescued by transfecting a form of CRT that is not targeted to the ER. CRT is the first example of a protein that relies on retrotranslocation to control its compartmentalization in the cell.

**Autophagy is Activated During ER Stress via the ER-resident Transmembrane Kinase IRE1**

M. Ogata,[1,2] F. Urano,[3] N. Mizushima,[4] K. Imaizumi[1]; [1]Faculty of Medicine, University of Miyazaki, Miyazaki, Japan, [2]Graduate School of Biological Sciences, NAIST, Nara, Japan, [3]Program in Molecular Medicine, University of Massachusetts Medical School, Worcester, MA, [4]Department of Bioregulation and Metabolism, Tokyo Metropolitan Institute of Medical Science, Tokyo, Japan

The endoplasmic reticulum (ER) is the compartment in which protein folding occurs prior to transport to various intracellular organelles. A number of cellular stress conditions lead to the accumulation of unfolded or misfolded proteins in the ER lumen, which constitutes a fundamental threat to the cell and triggers the unfolded protein response (UPR) to avoid cell damage. The UPR involves at least three distinct components, namely transcriptional induction of genes encoding ER-resident chaperones to facilitate protein folding, translation attenuation to decrease the demands made on the organelle and ER-associated degradation (ERAD) to degrade the unfolded proteins accumulated in the ER. Despite of extensive characterization of the signaling pathway for the UPR during ER stress, the morphological changes after ER stress are not well understood. Therefore, we performed electron microscopical examination of cells that were exposed to ER stress. In SK-N-SH neuroblastoma cells, treatment with tunicamycin, DTT, and thapsigargin induced the formation of autophagosomes, which were recognized at the ultrastructural level as double-

membrane vacuolar structures containing visible cytoplasmic contents. Immunoblot analysis revealed that the activated form of LC3 (LC3-II) is increased by ER stress, indicating that ER stress activates autophagy systems. In IRE1α-deficient cells, the formation of autophagic vacuoles induced by ER stress was inhibited. This result showed that IRE1α is essential for autophagy activation after ER stress. Furthermore, cell death induced by ER stress was accelerated by treatment with 3MA, a classical inhibitor of autophagy, suggesting that autophagy plays important roles in cell survival after ER stress.

**Cold Adaptation in Yeast: the Role of ER-associated Degradation and Sterol Biosynthesis**

R. Wright,[1] A. Felthauser,[1] J. Merkel,[1] A. Sturm,[2] M. Bard[2]; [1]Department of Genetics, Cell Biology, and Development, University of Minnesota, Minneapolis, MN, [2]Department of Biology, Indiana University-Purdue University Indianapolis, Indianapolis, IN

In a search for genes involved in membrane biogenesis in yeast, we discovered an unexpected link between cold adaptation and the endoplasmic reticulum (ER) quality control system known as ERAD (ER-associated degradation). Through the process of ERAD, short-lived, misfolded, or unassembled proteins are ubiquitinated and degraded by the proteasome. In a subset of ERAD mutants (*ubc7, cue1,* and *doa10)* expression of increased HMG-CoA reductase results in cold-sensitivity, such that the mutant strains are unable to grow at temperatures of 16°C or lower. In addition, the *UBC7, CUE1* and *DOA10* genes are required for growth at temperatures of 10°C or lower. Analysis of the sterol composition of these cold-sensitive mutants provides a possible mechanistic explanation of the relationship between ERAD, sterol metabolism, and growth at cold temperatures. In the mutant strains, the overall sterol composition is altered, such that the mutants contain decreased levels of squalene and increased levels of lanosterol. These results suggest that a primary defect produced by loss of *UBC7, CUE1,* or *DOA10* function is the inability to properly regulate sterol metabolism. In turn, this altered sterol composition may lead to cold sensitivity. Consistent with this hypothesis, loss of any non-essential gene required for sterol biosynthesis in yeast (*ERG2, 3, 4, 5, 6 24,* and *28)* results in cold-sensitivity. Thus, regulation of sterol biosynthesis appears to be critical for cold adaptation in the yeast, and ERAD plays a role in that regulation.

599

**The Role of IRE1's Kinase Domain during the Unfolded Protein Response**

A. Chawla, M. Niwa; Biology, UCSD, La Jolla, CA

The unfolded protein response (UPR) is a stress response pathway, sensing the accumulation of unfolded proteins in the endoplasmic reticulum (ER), and relaying this information to the nucleus. In yeast, IRE1, an ER resident transmembrane receptor kinase/ endoribonuclease, senses the presence of unfolded proteins. Rising levels of unfolded proteins, lead to IRE1's oligomerization and kinase activation. Activated IRE1 then functions as the site-specific endoribonuclease, cleaving a unique intron from HAC1 mRNA. The spliced form of HAC1 mRNA codes for a potent UPR specific transcription factor, which turns on the expression of ER chaperones and protein folding enzymes, ultimately allowing for the re-establishment of ER protein homeostasis, and turning off the IRE1 nuclease. We have found a novel IRE1 mutant which seems to be impaired in the recovery phase. In wild-type cells, HAC1 splicing, peaks at ~2hrs (60% spliced HAC1), after which it starts to decline, suggesting recovery from ER stress. In the case of the mutant however, HAC1 splicing reaches ~80% of wild-type levels by 2hrs, and is sustained for an extended amount of time (upto 8hrs). To examine if ER stress is sustained, even after HAC1 splicing, in cells carrying the mutant IRE1, we over-expressed one of the major ER chaperones, KAR2, but this did not help the mutant IRE1 to recover faster. In addition, increasing HAC1 splicing in the mutant cells to the level similar to wild-type, did not aid in recovery of the mutant. Together, these observations suggest that the sustained splicing observed in the mutant cells results from the inability of IRE1 to turn off its nuclease. We are currently investigating the molecular bases of the mechanism of shutting off IRE1.

**Dynamic Association of Rab and Arf GTPases with Adiposomes (Lipid Droplets)**

P. Liu,[1] R. Bartz,[1] J. K. Zehmer,[1] Y. Ying,[1] M. Zhu,[1] G. Serrero,[2] Y. Zhao,[3] R. G. W. Anderson[1]; [1]Cell Biology, UT Southwestern Medical Center, Dallas, TX, [2]A&G Pharmaceutical Inc, Columbia, MD, [3]Biochemistry, UT Southwestern Medical Center, Dallas, TX

Recent proteomic and immunoblotting analysis of isolated lipid droplets suggests they are specialized organelles involved in membrane traffic. For this reason we have introduced the term adiposome to denote organelle status. Proteins that appear to be highly enriched in adiposomes are the Rab GTPases. Over 17 different Rabs have been identified that are enriched in this compartment. Here we present three lines of evidence that GTPases involved in regulating membrane traffic are functionally associated with adiposomes. First, we assayed for the ability of Rab GDI to remove Rabs from isolated adiposomes. Using immunoblotting we detected the removal of four different Rabs by GDI in the presence of GDPβs but not GTPγs. Next we used the GDI treated adiposomes to see if Rabs could be recruited from cytosol. Multiple Rabs including Rab5 were recruited and recruitment was dependent on both GTP and the concentration of cytosol. Recruitment appeared to be saturable and individual Rabs did not compete with each other, suggesting the presence of Rab-specific binding sites on adiposomes. The Rab5 effector EEA1 was also recruited to adiposomes in the presence of GTP but not other nucleotides. We also found that multiple Arf GTPases were recruited to adiposomes in response to GTP, including Arf1. Interestingly, coordinate with Arf1 recruitment, the coatomers βCOP and εCOP appeared, suggesting membrane budding activity is associated with adiposomes. These results support our hypothesis that adiposomes are organelles involved in membrane lipid traffic.

**Lipid Body (Droplet) Metabolism is Controlled by Patatin-like Phospholipase Domain Containing Protein 5 (PNPLA5)**

E. B. Goldberg, W. J. Brown; Molecular Biology & Genetics, Cornell University, Ithaca, NY

Lipid bodies (lipid droplets, adiposomes) are highly conserved storage organelles for neutral lipids and cholesterol esters. Recently, a new family of cytoplasmic lipases named Patatin-like Phospholipase Domain Containing proteins (PNPLA1-5) has been discovered to play a key role in the hydrolysis of stored triglycerides and in the regulation of lipid body metabolism. We report here that PNPLA5, a previously uncharacterized member of this family, also plays an instrumental role in lipid body maintenance. In transfected HeLa cells grown under normal culture conditions, GFP-PNPLA5 was found diffuse in the cytoplasm and partially associated with lipid bodies. However, following induction of lipid body formation with excess oleic acid, GFP-PNPLA5 was located primarily on lipid bodies. Importantly, following lipid loading, over-expression of GFP-PNPLA5

visibly reduced the size of induced lipid bodies. In addition, when cells were starved of lipids to deplete the lipid body pool, GFP-PNPLA5 was found completely cytoplasmic. Finally, following lipid loading, GFP-PNPLA5 was found to co-localize with another family member, adiposome triglyceride lipase (ATGL) (a.k.a. PNPLA2), although ATGL was more punctate and less uniform in distribution on lipid bodies than GFP-PNPLA5. Our data reveals that PNPLA5 localizes to the outside of lipid bodies, much like the pattern previously reported of other PNPLA family members. PNPLA5 plays an important role in the degradation of lipid bodies, most likely by hydrolysis of triglycerides.

**Regulation of Lipid Accumulation by ADP Ribosylation**

R. Bartz,[1] J. Seemann,[1] J. K. Zehmer,[1] G. Serrero,[2] K. Chapman,[3] R. G. W. Anderson,[1] P. Liu[1]; [1]Cell Biology, UT Southwestern Medical Center at Dallas, Dallas, TX, [2]A&G Pharmaceutical Inc., Columbia, MD, [3]Department of Biological Sciences, University of North Texas, Denton, TX

Lipid droplets, or adiposomes, are intracellular organelles that are composed of a neutral lipid core (e.g. triacylglycerol and cholesterol esters) surrounded by phospholipids and proteins. While the biogenesis of these organelles remains elusive, the function of lipid droplets in fat storage is clearly established. Here, we report that fat storage in these organelles is regulated by ADP ribosylation. Previous work has shown that caveolin-1 (Cav-1) is associated with adiposomes and that brefeldin A (BFA) causes the amount of Cav-1 in this compartment to increase. We find that short-term (30 min) exposure of cells to BFA causes a marked increase in the amount of Cav-1 in adiposomes, which is not blocked by protein synthesis inhibitors. The BFA stimulated enrichment of Cav-1 presumably is caused by the migration of Cav-1 from other sites in the cell. Unexpectedly, if we incubate cells longer (5-12 hr) in the presence of BFA, lipid droplets completely disappear from the cell. This effect of BFA is dependent on protein synthesis, which suggests that BFA is affecting gene expression. We determined that BFA is enhancing the secretion of fatty acids into the media. Using multiple approaches we determined that the affects of BFA are not due either to a stimulation of the unfolded protein response or to disruption of the Golgi apparatus. BFA is known to stimulate the mono-ribosylation of both the transcriptional regulator C-terminal binding protein (CTBP) and glyceraldehyde-3-phosphate dehydrogenase. Importantly we found that BFA stimulated lipid loss is blocked by two different inhibitors of protein ribosylation, nicotinamide and 3-aminobenzamide. We speculate that lipid storage in many cell types is controlled through mono-ADP ribosylation of proteins involved in transcriptional regulation.

**Proteomic Analysis of *Drosophila* Embryonic Lipid Droplets: Storage Depots for Maternally Provided Proteins**

S. Cermelli,[1] Y. Guo,[2] M. A. Welte,[2] S. P. Gross[1]; [1]Dev. and Cell Bio, University of California, Irvine, Irvine, CA, [2]Department of Biochemistry, Brandeis University, Waltham, MD

Lipid droplets are ubiquitous energy-storage organelles of eukaryotes. Despite characterized central roles for cholesterol homeostasis and lipid metabolism, their function is poorly understood. To determine the protein complement of lipid droplets from developing Drosophila embryos, we purified lipid droplets by floatation to near homogeneity, as judged by the absence of markers for other organelles, and analyzed the associated proteins by 2D gel electrophoresis and capillary LC-MS/MS. This sensitive approach allowed us to identify many more proteins (~250) than previously published for lipid droplets from other systems. Important functional groups include known droplet-associated proteins, enzymes involved in fatty acid metabolism, signaling molecules, proteins involved in membrane trafficking, and cytoskeleton associated proteins. In particular, we find homologues of most of the proteins previously identified to be present on mammalian lipid droplets. It should therefore be possible to use Drosophila embryonic lipid droplets as a model for studies of lipid metabolism and related diseases in humans. The list of droplet-associated proteins is surprisingly diverse. Among the unexpected candidates are histone proteins. Using a combination of biochemistry, genetics, real-time imaging and cell biology, we confirm that both endogenous histones and a Histone-GFP fusion protein are present in large quantities on lipid droplets of early embryos, but not of cultured cells. Quantitation of GFP signal and transplantation experiments suggest that histones are transferred from droplets to nuclei as development proceeds. As histone association with droplets starts during oogenesis, droplets may sequester maternally provided histones until they are needed. More generally, we propose that lipid droplets can serve as transient storage depots for proteins that lack appropriate binding partners in the cell. We propose that such sequestration is not only important for early development, but provides a general strategy for handling excess proteins.

**The Crystal Structure of Yeast Protein Disulfide Isomerase Reveals Asymmetry Between Its Active Sites**

G. Tian,[1] S. Xiang,[2] W. J. Lennarz,[1] H. Schindelin[2]; [1]Department of Biochemistry and Cell Biology, Stony Brook University, Stony Brook, NY, [2]Department of Biochemistry and Cell Biology and Center for Structural Biology, Stony Brook University, Stony Brook, NY

Protein disulfide isomerase is an enzyme that catalyzes the formation and rearrangement of disulfide bonds in newly synthesized proteins. It contains four domains, two catalytically inactive thioredoxin domains inserted between two active thioredoxin domains, and an acidic C-terminal tail. We have determined the crystal structure of yeast PDI at a resolution of 2.4 Å and found that the four thioredoxin domains are arranged in the shape of a twisted “U” with the active sites facing each other across the long sides of the “U”. The inside surface of the “U” is enriched in hydrophobic residues, thereby facilitating interactions with misfolded proteins. The overall domain arrangement, active site location and surface features strikingly resemble the *Escherichia coli* disulfide isomerase DsbC. Based on the structure, site-directed mutagenesis and domain deletion studies were carried out. Biochemical studies demonstrate that all domains of PDI, including the C-terminal tail, are required for full catalytic activity and the two active sites of yeast PDI were revealed to be asymmetric in the enzyme’s catalytic functions. (Supported by NIH grant GM33184 to WJL and DK54835 to H.S.)

**Quality Control of a Bacterial Periplasmic BraC Protein in Mammalian Cells**

Y. Shono, H. Shinmura, Y. Nagahara, M. Tanaka; Biotechnology, Tokyo Denki University, Saitama, Japan

The folding and assembly of secretory protein is monitored by chaperons such as calnexin and calreticulin throughout their binding abilities to a specific type of the N-liked oligosaccharide in the endoplasmic reticulum (ER). We, then, wondered how a secretory protein having no conventional N-glycosylation site (-NXT/S-) is discriminated in the system of ER quality control. To study the quality control of secretory protein

with no N-glycan, we transiently transfected a plasmid, pSV2secBraC encoding a bacterial LIVAT-binding protein (BraC protein) fused with a secretion signal of MHC class I H2-$K^d$, into COS-7 cells. Immunoprecipitation with anti-BraC antibody and the subsequent western blotting analysis of the transfected cells showed several molecular species of BraC proteins with higher molecular weights other than a matured BraC protein. Addition of either N-glycosidase F or endoglycosidase H to the immuno-beads diminished the molecular species with higher molecular weight, so a part of the heterogeneity is due to the modification with an N-linked glycan curiously attached to the protein without any N-glycosylation sites. To test the sequence requirements of the modification, we next transfected some derivatives of the pSV2secBraC into COS-7 cells. The modification did not occur when the addition of other amino acid residues or peptides to the C-terminus of BraC protein. Also the removal of the C-terminal lysine of BraC protein brought the modification of BraC protein to a halt. Moreover, the modification occurs when secretion signal was changed to other secretory signals instead of MHC class I H2-$K^d$. This phenomenon was obtained from human hepatoma cells (HuH-7) transiently transfected with pSV2secBraC. Consequently, this unusual modification of N-linked glycan must occur in wide variety of cells including human cells and have an important role in quality control of proteins.

606

**The Quality Control of Human Blood Coagulation Factor X Without N-glycan**

H. Kawashima, Y. Nagahara, M. Tanaka; Tokyo Denki University, Hiki-Gun, Japan

The quality control of secretory glycoprotein is involved in calnexin and/or calreticulin binding cycle in the endoplasmic reticulum. However, the molecular mechanism of quality control of non-glycosylated protein is obscure. To study the mechanism, we constructed plasmids expressing human blood coagulation factor X (FX) which has no N-glycosylation sites. We obtained three plasmids that encode FX mutants with single N-glycosylation site, T223A or T233A, and both of them, T223A and T233A by site-directed mutagenesis. These plasmids were transiently transfected into COS-7 cells, and mutated FX was visualized with immunoblotting. FX mutants were detected in both the cells and the medium. The two mutants, FX(T223A) and FX(T233A) in the cells showed their apparent molecular weight 4kDa lower than that of FX precursor, while molecular weight of the mutant, FX (T223A/T233A) showed further 4kDa lower than that of two mutants. Since these differences among FX and the mutants in the cells were diminished with N-glycosidase F, these differences were due to the N-glycan moieties. FX mutants in the medium seemed to be lower size than intracellular FX mutants. Differences of apparent molecular weights between wild type and the mutants of FX in the medium were diminished with N-glycosidase F, but they had no susceptibilities with Endoglycosidase H. The FX mutants would be normally transported from ER through Golgi network into medium. Similar results obtained from the human hepatoma cells, HuH-7, transiently transfected with FX (T223A/T233A). Furthermore, we established stable transfectants of BALB/c 3T3 cells expressing and secreting the FX (T223A/T233A) to the medium. These results suggest that the FX does not always require its N-glycan for secreting from the cell. An unidentified molecular system may also participant to the quality control of protein.

607

**The Skeletal Muscle Isoform of Calsequestrin is Retained within Streaming Cisternae of Endoplasmic Reticulum Bound to a Subset of Microtubules**

T. D. Houle, M. L. Ram, P. Sateesh, S. E. Cala; Physiology, Wayne State University, Detroit, MI

Cardiac (CASQ2) and skeletal muscle calsequestrin (CASQ1) are abundant lumenal ER/SR proteins in muscle cells. Each CSQ isoform co-traffics with other protein components of the respective Ca2+-release complexes in heart and muscle, although the trafficking steps leading to its eventual concentration in terminal cisternae remain unknown. This trafficking is important to understand because it is so completely altered in animal models of heart failure, and might have a role in disease progression. To study the early steps in CSQ trafficking through the secretory pathway, we overexpressed the two isoforms of CSQ in several nonmuscle cell lines. As we recently reported, cardiac CSQ is retained in ER compartments in all nonmuscle cells. Confocal imaging of CSQ-containing compartments showed a co-localization with GRP94 and calnexin. CSQ was usually restricted to more perinuclear cisternae, and often appeared as a few distinct polygons. In dramatic contrast, skeletal muscle CSQ displayed a peculiar streaming pattern of ER that appeared to emanate from ER and extend to the microtubule-organizing center (MTOC), and was disrupted by the microtubule depolymerizing agent nocadazole. DsRed fusion proteins generated intracellular patterns for CSQ that were somewhat distinct, yet the streaming ER patterns remained vivid. Live cell imaging revealed a highly dynamic streaming ER, with CSQ appearing to move retrogradely from the MTOC and distal ER towards the cell periphery. Interestingly, when CSQ2 was co-overexpressed with the cardiac CSQ cDNA, streaming ER disappeared and both proteins co-localized in a typical cardiac pattern. Our data indicate that unique isoform-specific sequences in CSQ can retain the protein in ER, or permit trafficking beyond ER exit sites. As lumenal ER cargo, CSQ isoforms may contain isoform-specific binding sites to permit interaction with microtubule motor complexes.

608

**Polymyxin B Decreases the Permeability of the Rough Endoplasmic Reticulum to Small Molecules**

W. F. Wonderlin; Biochemistry & Molecular Pharmacology, West Virginia University, Morgantown, WV

We have previously proposed that the release of a nascent chain from a translationally-active, ribosome-bound translocon (RBT) creates an open pore through which small molecules can cross the membrane of the rough endoplasmic reticulum (RER) (JBC, 276:22655; JBC, 278:4397), but a lack of pharmacological tools has limited our study of this pathway. We have continued our study of the permeability of the RER in CHO-K1 cells to 4-methylumbelliferyl-α-D-glucopyranoside (4MG), whose entry can be detected when it is hydrolyzed by lumenal α-glucosidase II. We report here that the increased entry of 4MG produced when nascent chains are released by puromycin (PUR) can be blocked by Polymyxin B (PMB), a cyclic decapeptide with five positively-charged residues and a 6-carbon tail. The effect of PMB on the PUR-stimulated entry of 4MG was biphasic, with modest stimulation at low concentrations and complete inhibition at higher concentrations ($K_i$ of 20-35 μg/ml, ~20 μM). PMB also produced a biphasic stimulation and inhibition of the basal (*i.e.*, PUR independent) entry of 4MG. PMB-nonapeptide, an analog of PMB in which the lipid tail and one charged residue have been removed, produced similar biphasic effects, but with a 2-fold decrease in potency. Although PMB completely blocked the PUR-stimulated entry of 4MG, it reduced the basal permeability by only 10-20%, considerably less than the >80% reduction observed when high salt was used to strip translationally-inactive ribosomes from the RER. We surmise that the partial block of the salt-sensitive entry of 4MG reflects the entry of 4MG via multiple states of the open RBT, or perhaps additional RBT-independent pathways, of which only one is

inhibited by PMB. PMB should be a useful tool for dissecting the pathways for small molecules to cross the membrane of the RER.

609

**Ubiquitin Modification of Serum and Glucocorticoid-induced Protein Kinase (SGK-1) is Associated with its Subcellular Localization**

D. R. Brickley, J. Nicolarsen, L. Belova, A. M. Bogusz, S. D. Conzen; Department of Medicine, University of Chicago, Chicago, IL

SGK-1 is a member of the AGC family of serine/threonine kinases and shares close sequence homology to AKT-1/PKB. Unlike AKT-1, SGK-1 mRNA expression is induced by glucocorticoids, aldosterone, serum, and in response to various environmental stressors. In addition, SGK-1 is rapidly degraded by the ubiquitin-proteasome pathway. In breast epithelial cells, we have previously observed that ubiquitin-modified SGK-1 is found exclusively in a membrane-associated cellular fraction. By examining both immunofluorescent detection of endogenous SGK-1 protein and SGK-1 GFP fusion proteins, we show here that wild type (WT) SGK-1 localizes primarily to the endoplasmic reticulum (ER) and mitochondria; however when aa10-24 are deleted (Dl10-24-SGK-1), SGK-1 localization is disrupted, and the protein is distributed homogenously throughout the cell. Furthermore, Dl10-24-SGK-1 is neither ubiquitinated nor degraded as efficiently as WT SGK-1. Interestingly, deletion of aa15-18 disrupts SGK-1's ER targeting and causes almost exclusive mitochondrial targeting. This suggests that within aa15-18 there may exist an ER localization/retention sequence which when deleted results in a default localization to the mitochondria. Thus far, our mutational analysis has demonstrated that SGK-1's ubiquitin modification and its localization to the ER/mitochondria are correlated, suggesting that SGK-1 localization may be required for interaction with its E3 ligase. We have recently found that the chaperone-dependent E3 ligase, CHIP, is required for SGK-1's rapid protein turnover. Indeed, both SGK-1 and CHIP appear to co-localize at or near the ER. Studies are ongoing to determine whether apoptotic stress induces differential subcellular localization and/or ubiquitin-mediated degradation of endogenous SGK-1.

**Stable Ribosome Binding to the Endoplasmic Reticulum Enables Compartment-Specific Regulation of mRNA Translation**

S. B. Stephens,[1] R. D. Dodd,[1] J. W. Brewer,[2] P. J. Lager,[3] J. D. Keene,[3] C. V. Nicchitta[1]; [1]Department of Cell Biology, Duke University Medical Center, Durham, NC, [2]Department of Microbiology and Immunology, Loyola University, Chicago, IL, [3]Department of Molecular Genetics and Microbiology, Duke University Medical Center, Durham, NC

mRNAs are distributed between the cytosol and endoplasmic reticulum (ER) compartments of eukaryotic cells by a process of positive selection; mRNAs encoding signal sequences are co-translationally directed to the endoplasmic reticulum (ER) via the signal recognition particle pathway. Following the termination of translation, ER-bound ribosomes are thought to dissociate from the ER to rejoin a common cytosolic pool, thereby completing a translation-driven cycle of RNA partitioning. At present little is known regarding the physiological basis for termination-coupled ribosome release. We examined ribosome and mRNA partitioning during the unfolded protein response, a stress response pathway that suppresses initiation and thereby synchronizes translational termination. We report that physiological induction of termination results in the accumulation, rather than the expected release, of ER-associated ribosomes. Under these conditions, cytosolic translation is suppressed and mRNA/ribosome complexes undergo efficient disassembly. In contrast, translation on the ER is sustained, with mRNAs being present in small polyribosome complexes. Significantly, ER-bound ribosomes were found to participate in the translation of mRNAs encoding soluble as well as secretory proteins. These studies demonstrate that ribosome exchange on the ER is independent of termination and identify new and unexpected roles for ER-bound ribosomes in the translational regulation of cellular protein synthesis.

611

**Vaccinia Virus Replication and Assembly: Manipulation and Utilization of Intracellular Membranes**

P. Traktman, J. P. Mercer, B. Unger; Microbiol. & Molecular Genetics, Medical College of Wisconsin, Milwaukee, WI

Vaccinia virus replicates solely within the host cell cytoplasm. Among the ~200 viral proteins are those mediating genome replication and virion morphogenesis. These processes are regulated by viral protein kinases and involve the remodeling of membranes of the secretory pathway. We have found by immunoelectron microscopy, using antisera directed against cellular PDI, the viral SSB, and BrdU, that viral DNA replication occurs within cytoplasmic foci surrounded by ER. We will present a time course of the formation and enlargement of these sites and address the interactions between ER and viral replication proteins. The virion membrane has been proposed to assemble *de novo* or to derive from cellular ERGIC; recent reports dispute any role for COP II or COP I machinery. We will present new insights into the biogenesis of the virus membrane. (I) Inhibition of the viral F10 kinase prevents membrane biogenesis; F10 binds to PIPs and associates with membranes. Morphogenesis resumes synchronously when *ts*F10-infected cultures are shifted to the permissive temperature. Inclusion of H89, an inhibitor of ER exit site formation, or cerulenin, an inhibitor of *de novo* lipid synthesis, block the restoration of virion production. (II) Phosphoprotein profiling of cellular signaling molecules indicates that the phosphorylation status of several associated with membrane trafficking changes upon infection. (III) Iodixanol gradient fractionation has allowed us to isolate "viral vesicles" seen when viral proteins required for membrane biogenesis are repressed. These membranes are distinct from the ER, ERGIC or Golgi and contain key proteins destined for encapsidation into the virion membrane. Progress in understanding the origin of these membranes, as well as their lipid and protein content, will be discussed.

**Characterizing the Substrate Binding Domain of ERdj3, a Mammalian ER DnaJ Protein**

Y. Jin, L. Hendershot; St.Jude Children's Research Hospital, Memphis, TN

ERdj3 has been identified as a soluble mammalian endoplasmic reticulum (ER) DnaJ family member. We previously demonstrated the existence of a large preassembled ER-localized multi-protein complex including BiP and other chaperones. Binding of the complex to unassembled, incompletely folded immunoglobulin heavy chain is accompanied by ERdj3, which is not part of the preassembled complex. *In vivo* binding assays demonstrated that an ERdj3 mutant, which does not interact with BiP, binds to unfolded substrates even better than wild type ERdj3. This result strongly suggests that ERdj3 binds to substrates directly, which was verified by *in vitro* binding assays. While the interaction of DnaJ proteins with their Hsp70 partner is well characterized, less is understood about the interaction of DnaJs with substrates. In order to begin mapping ERdj3's substrate binding domain, we aligned the amino acid sequence of ERdj3 with Ydj1 and Sis1, two yeast cytosolic DnaJs for which structural data are available. Unlike Sis1 which lacks the Cys-rich domain II that is inserted into domain I of Ydj1, ERdj3 is predicted to possess a domain II,

albeit a smaller and atypical Cys-rich domain as compared to Ydj1. Based on the crystal structures of Ydj1 and Sis1 and the predicted secondary structure of ERdj3, we defined domain boundaries. Deletion mutants were made and in vivo binding assay were performed. Our data indicate that domain II (which is very highly conserved evolutionarily among ERdj3s) plays a critical role in the binding of ERdj3 to substrates and that domain Ia also contributes. Delineation of the ERdj3 substrate binding domain is being confirmed by testing the ability of recombinant ERdj3 mutant proteins to bind and refold non-native proteins and to block the aggregation of denatured proteins.

613

**Exploration of the Functional and Organizational Principles of the Yeast Early Secretory Pathway Through An Epistatic Mini Array Profile (E-MAP)**

M. B. Schuldiner,[1] N. J. Krogan,[2] S. R. Collins,[1] N. J. Thompson,[2] V. Denic,[1] A. Bhamidipathi,[1] T. Punna,[2] J. Ihmels,[1] B. Andrews,[2] C. Boone,[2] J. F. Greenblatt,[2] J. S. Weissman[1]; [1]CMP, UCSF, San Francisco, CA, [2]Banting and Best Department of Medical Research,, University of Toronto, Toronto, ON, Canada

We present a strategy for generating and analyzing comprehensive genetic interaction maps, termed E-MAPs (Epistatic Mini Array Profiles), comprising quantitative measures of aggravating and buffering or suppressing interactions between gene pairs. Crucial to the analysis of E-MAPs is their high-density nature made possible by focusing on largely self-contained gene subsets and including essential genes. To enable genetic analysis of essential proteins we developed a novel technique, termed DAmP (Decreased Abundance by mRNA Perturbation) for rapidly constructing hypomorphic alleles. Described here is the analysis of an E-MAP of genes acting in the early secretory pathway (ESP) of *Sacchromyces cerevisiae*. Hierarchical clustering of our interaction network, together with the application of novel analytical strategies and specific experimental verification revealed or clarified the role of many proteins in the ESP. At a broader level, analysis of the E-MAP delineated pathway organization and components of physical complexes, and illustrated the interconnection between the various secretory processes. Extension of this strategy to other logically connected gene subsets in yeast and higher eukaryotes should provide critical insights into the function and organizational principles of biological systems.

614

**The Cytoplasmic Hsp70-chaperone Machinery Subjects Misfolded and ER Import Incompetent Proteins to Degradation via the Ubiquitin-proteasome System**

S. Park,[1] N. Bolender,[1] J. Takeuchi,[2] P. Coffino,[2] D. H. Wolf[1]; [1]Institut für Biochemie, Universität Stuttgart, Stuttgart, Germany, [2]Dept. of Microbiology and Immunology, University of California, San Francisco, San Francisco, CA

We have shown in yeast that degradation of CPY*, a soluble misfolded protein of the endoplasmic reticulum, requires the trimeric Cdc48-Ufd1-Npl4 complex as well as the UBA-UBL proteins Dsk2p and Rad23p of the cytosol for their degradation via the ubiquitin-proteasome system (Kostova and Wolf (2003) EMBO J 22, 2309-2317; Medicherla et al., (2004) EMBO Rep. 5, 692-697). Here we show that ER import defective CPY* (Δss CPY*), derivatives thereof (e.g., ΔssCPY*-GFP) or ER import incompetent wild type CPY are rapidly degraded via the cytosolic ubiquitin proteasome system. In contrast to the soluble ERAD substrate CPY*, degradation of these proteins is independent of the trimeric Cdc48 complex as well as of Dsk2p and Rad23p. Instead, their degradation requires the cytosolic Hsp70 chaperones of the Ssa type as well as a variety of co-chaperones. Most interestingly, while proteasomal degradation of signal sequence deleted, cytoplasmically localized ΔssCPY*-GFP requires the Ssa1-machinery, degradation of a GFP fusion containing the C-terminal 37 amino acid region of ornithine decarboxylase, a ubiquitin-independent degradation tag (Zhang et al. (2003), EMBO J. 22, 1488-1496), is independent of this machinery.

615

**ERp29 Triggers a Conformational Change in Polyomavirus to Stimulate Membrane Binding**

E. K. Rainey, B. Magnuson; Cell and Developmental Biology, University of Michigan Medical School, Ann Arbor, MI

Membrane penetration of non-enveloped viruses is a poorly understood process. We have investigated early stages of this process by studying the conformational change experienced by polyomavirus (Py) in the lumen of the endoplasmic reticulum (ER), a step that precedes its transport into the cytosol. We show that a PDI-like protein, ERp29, exposes the C-terminal arm of Py's VP1 protein, leading to formation of a hydrophobic particle that binds to a lipid bilayer; this reaction likely mimics initiation of Py penetration across the ER membrane. Expression of a dominant-negative ERp29 decreases Py infection, indicating ERp29 facilitates viral infection. Interestingly, cholera toxin, another toxic agent that crosses the ER membrane into the cytosol, is unfolded by PDI in the ER. Our data thus identify a novel ER factor that mediates membrane penetration of a non-enveloped virus and suggest that PDI family members are generally involved in ER remodeling reactions.

**Polarity Establishment and Orientation during Morphogenesis are Regulated by Two Distinct Molecular Cues**

A. Datta,[1] W. Yu,[1] K. D. Liu,[1] P. R. Brakeman,[1] T. Jou,[2] M. M. P. Zegers,[3] K. E. Mostov[1]; [1]Departments of Anatomy and Biochemistry and Biophysics, University of California San Francisco, San Francisco, CA, [2]Department of Internal Medicine, National Taiwan University Hospital and National Taiwan University College of Medicine, Taipei, Taiwan Republic of China, [3]Epithelial Pathobiology, Department of Surgery, University of Cincinnati College of Medicine, Cincinnati, OH

Normal epithelial cells must form and maintain a polar architecture for their function *in vivo*. Development of epithelial organs requires both the establishment of polarity as well as the determination of the orientation of polarity. Using MDCK epithelial cysts grown in a 3-dimensional collagen matrix as a model system, we sought to distinguish the pathways that regulate the orientation vs. establishment of polarity. β-1 Integrin mediated downstream signals have been shown to regulate the orientation of polarity in MDCK cysts through a Rac1 dependent pathway (*O'Brien et.al*, Nat. Cell Biol., 2001, 3(9):831, *Yu et.al.* Mol. Biol. Cell 2005, 16(2):433). Here we report that Cdc42 is a key component of the pathway that establishes polarity in 3-dimensions. The loss of Cdc42 function leads to a loss of polarity in a 3-dimensional collagen culture. The loss of Rac1, in contrast, has been shown to lead to an inversion of polarity orientation. The expression of a constitutively activated Cdc42 can bypass the

requirement for Integrin signal for determining the orientation of polarity. However, in contrast to Rac1, the addition of exogenous laminin is not sufficient to rescue the polarity defect due the loss of Cdc42, indicating that Cdc42 acts downstream of Integrin-ECM signals in the polarity pathway. While Rac1 regulates the orientation of polarity, our data indicates that Cdc42 is a part of the cellular machinery that provides the ultimate spatial cue for the establishment of epithelial polarity during morphogenesis.

617

**Apical Targeting of Syntaxin 3 is Essential for Epithelial Cell Polarity**

N. Sharma,[1] S. Low,[1] S. Misra,[2] B. Pallavi,[1] T. Weimbs[1]; [1]Department of Molecular, Cellular, and Developmental Biology, University of California Santa Barbara, Santa Barbara, CA, [2]Department of Molecular Cardiology, Cleveland Clinic, Cleveland, OH

In epithelial cells, syntaxin 3 localizes to the apical plasma membrane and is involved in membrane fusion of apical trafficking pathways. Here, we show that syntaxin 3 contains a necessary and sufficient apical targeting signal centered around a conserved FMDE motif. Mutation of any of three critical residues within this motif leads to loss of specific apical targeting. Modeling based on the known structure of syntaxin 1 revealed that these residues are exposed on the surface of a three-helix bundle. Syntaxin 3 targeting does not require binding to Munc18b. Instead, syntaxin 3 recruits Munc18b to the plasma membrane. Expression of mis-localized, mutant syntaxin 3 in MDCK cells leads to basolateral mis-targeting of apical membrane proteins, disruption of tight junction formation, and loss of ability to form an organized polarized epithelium. These results indicate that SNARE proteins contribute to the overall specificity of membrane trafficking in vivo, and that the polarity of syntaxin 3 is essential for epithelial cell polarization.

618

**Muc4-ErbB2 Complex Formation and Signaling in Polarized CACO-2 Epithelial Cells**

K. L. Carraway,[1] V. P. Ramsauer,[1] P. J. I. Salas,[1] C. A. C. Carraway[2]; [1]Cell Biology and Anatomy, University of Miami School of Medicine, Miami, FL, [2]Biochemistry and Molecular Biology, University of Miami School of Medicine, Miami, FL

This study was initiated to determine the mechanisms by which the membrane mucin Muc4 interacts with ErbB2 and regulates ErbB2 signaling in polarized epithelial cells. Muc4 serves as an intramembrane ligand for the receptor tyrosine kinase ErbB2. To examine the stoichiometry and formation of the Muc4-ErbB2 complex, the soluble, extracellular domain forms of Muc4 and ErbB2 were expressed with the Baculovirus Expression Vector System in High Five insect cells, as previously reported for secretion of the complex. The complex was purified by affinity chromatography and immunoprecipitation and biotinylated to determine its stoichiometry, which was 1:1. Using pulse-chase analyses, the time to complex formation was determined to be less than 15 min, compared to 45-60 min for complex secretion. In polarized CACO-2 cells, Muc4 expression causes localization of ErbB2, but not its heterodimerization partner ErbB3, to the apical cell surface, effectively segregating the two receptors. The apically located ErbB2 is phosphorylated on tyrosines 1139 and 1248, as determined by specific anti-phospho-ErbB2 antibodies. The phosphorylated ErbB2 in CACO-2 cells recruits the cytoplasmic adaptor protein Grb2, consistent with previous studies showing phosphotyrosine 1139 to be a Grb2 binding site. To address the issue of downstream signaling from apical ErbB2, we analyzed the three MAPK pathways of mammalian cells, Erk, p38 and JNK. Consistent with the more differentiated, polarized phenotype of the CACO-2 cells, p38 phosphorylation was robustly increased by Muc4 expression, with consequent activation of Akt. In contrast, Erk phosphorylation was weakly increased, and JNK phosphorylation was not changed. The ability of Muc4 to segregate ErbB2 from the other ErbB receptors and to alter downstream signaling cascades in polarized epithelial cells suggests that it has a role in regulating ErbB2 functions in differentiated epithelia.

619

**Lumen Formation and Tubulogenesis by MDCK Cells in Three-Dimensional Cultures Studied with Selective Plane Illumination Microscopy**

F. Pampaloni,[1] E. G. Reynaud,[1] K. Greger,[1] M. Marcello,[2] J. Swoger,[1] E. H. K. Stelzer[1]; [1]Cell Biology and Biophysics Programme, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany, [2]German Cancer Research Center, Heidelberg, Germany

It is known that Madin-Darby Canine Kidney cells form apicobasal polarized spherical shells (cysts) when grown in a three-dimensional matrix like Matrigel or collagen. MDCK cells and other 3D cellular model systems are very valuable to investigate the formation and function of glandular epithelia. We applied Selective Plane Illumination Microscopy (SPIM) to study the sequence of spatially and temporally regulated morphogenic events leading to lumen formation and branching tubulogenesis in 3D-cultured MDCK cells. SPIM is a new high-resolution fluorescence microscopy technique that has been developed for the modern life sciences. For the emerging field of 3D cell biology SPIM is an ideal instrument. It enables researchers to image a whole population of cells in their 3D context,to visualize their morphology in a matrix and to track cells through the context of surrounding tissue. In SPIM, detection of fluorescence light perpendicularly to the illumination axis (theta principle of detection) is combined with selective excitation of fluorophores within an entire plane by a focused laser light sheet. Therefore, selective plane illumination provides optical sectioning directly. Bleaching outside the volume of interest is avoided. Moreover, CCD camera-based wide-field detection provides high recording speed.

620

**Transglutaminase is Involved in UVB-induced NF-κB Activation in Corneal Epithelial Cells**

L. Tong,[1,2,3] R. M. Corrales,[1] L. Z. Chen,[1] C. S. de-Paiva,[1] D. Q. Li,[1] S. C. Pflugfelder[1]; [1]Ocular Surface Center, Cullen Eye Institute, Baylor College of Medicine, Houston, TX, [2]Singapore National Eye Center, Singapore, Singapore, [3]Singapore Eye Research Institute, Singapore, Singapore

Anti-transglutaminase(TG) strategies reduce inflammation in allergic conjunctivitis; however, the role of TG in the pro-inflammatory pathways in ocular surface epithelial cells has not been investigated. A human cornea epithelial cell line(T-HCEC) and primary human corneal epithelial cells(PCE) cultured from limbal explants were used. Cells were stimulated with a single dose of UVB at 20 $mJ/cm^2$ or tumour necrosis factor (TNF-α). RNA levels were assessed by RT-PCR and protein expression by immuno-cytochemistry and Western blotting. Culture media cytokine concentration was assayed with a bead-based sandwich immuno-fluorescence assay. TG activity was assessed by fluorescein-cadaverine uptake. UVB induced the clustering of TNF-α Receptor-I, which was inhibited by monodansyl-cadaverine(MDC), a TG inhibitor. UVB also stimulated

phosphorylation of JNK, as well as increased TG activity. Incubation with SP600125, a JNK inhibitor, reduced UVB-induced TG activity. The expression of TG-1 and TG-2 proteins was stimulated by UVB, but suppressed by MDC or SP600125. Similarly, TG-1 RNA expression was also stimulated by UVB and suppressed by MDC. UVB induced the translocation of p65 into nuclei of cells, activating the NFκB pathway: a similar effect to TNF-α stimulated cells. Incubation with MDC reduced this translocation, an effect similar to that of SN-50, a peptide inhibitor of p65 translocation. MDC also suppressed the TNF-α stimulated nuclear translocation of p65. TNF-α and IL-8 secretion into culture media were increased after UVB stimulation. Incubation with MDC reduced the concentration of TNF-α, but not of IL-8 after UVB. In cornea epithelial cells, TG can mediate activation of the stress induced NFκB pathway, secreting pro-inflammatory cytokines in a cytokine-selective fashion. UVB signaling involves TG dependent clustering of cell surface receptors. JNK may be an upstream signal for TG expression and activation. This pathway offers potential targets for treatment of ocular surface diseases.

621

**Zinc Transport in Proliferating and Differentiated Trophoblasts (BeWo) is Regulated Differently by Progesterone and is Associated with Changes in Zip4 and ZnT1 Levels**

X. Du, B. Lonnerdal, S. L. Kelleher; Nutrition, University of California Davis, Davis, CA

Zinc (Zn) is essential for normal fetal growth and development. During implantation, proliferating cytotrophoblasts invade the endothelium, and then differentiate into syncytiotrophoblasts transporting nutrients from mother to fetus. These distinct functions suggest unique Zn requirements. We hypothesize that trophoblast Zn transport is regulated by progesterone (PG), a steroidal hormone critical for trophoblast implantation and function, mediated via Zip4 (Zn uptake) and ZnT1 (Zn efflux). BeWo cells were grown in bicameral chambers or on glass coverslips and differentiated with forskolin (100μM) for 72 h. Cells were treated with PG (1μM) for 1 h, Zn transport was measured, Zip4 and ZnT1 protein abundance was determined by Western blot and localization demonstrated by confocal microscopy. While proliferating and differentiated trophoblasts transport similar amounts of Zn, proliferating cells retain more cellular Zn and differentiated cells efflux more Zn across the basal membrane; however, Zip4 (localized at the plasma membrane) and ZnT1 (localized to intracellular vesicles) abundance was similar. Progesterone reduced total Zn transport and basolateral Zn efflux and increased cellular Zn retention in proliferating cells which was associated with lower ZnT1 and higher Zip4 abundance. Progesterone had no effect on total Zn transport in differentiated cells; however, basolateral Zn efflux was decreased and cellular Zn retention was increased but both Zip4 and ZnT1 abundance were decreased. Our results indicate that proliferating trophoblasts preferentially retain Zn for cellular use while differentiated trophoblasts enhance Zn efflux to the fetus. While PG is essential for the establishment and maintenance of pregnancy, elevated PG during early pregnancy may impair cellular Zn uptake, thus interfering with invasion and during late pregnancy may reduce Zn transfer to the developing fetus through post-transcriptional changes in specific Zn transporters.

622

**Striking Differences in Activities of Antioxidant and Prooxidant Enzymes in the Normal Corneal Epithelium of Various Mammalia**

J. Cejkova,[1] J. Platenik,[2] M. Vejrazka,[2] C. Cejka,[1] S. Stipek,[2] T. Ardan,[1] J. Kovaceva,[1] A. Midelfart[3]; [1]Eye Histochemistry and Pharmacology, Institute of Experimental Medicine, Academy of Sciences of the Czech Republic, Prague, Czech Republic, [2]First Institute of Medical Chemistry and Biochemistry, Charles University, Prague, Czech Republic, [3]Department of Ophthalmology, Faculty of Medicine, Trondheim, Norway

Under normal conditions antioxidants are balanced in the corneal epithelium with reactive oxygen species generation without any toxic effects. The danger from oxidative stress appears when the natural antioxidants are overwhelmed leading to antioxidant/prooxidant imbalance. The aim of the present investigation is to examine activities of enzymes participating in the antioxidant/prooxidant balance in the normal corneal epithelium of various mammalia. The antioxidant enzymes (superoxide dismutase and glutathione peroxidase) and prooxidant enzymes (xanthine oxidoreductase/xanthine oxidase) were investigated biochemically. Results show that the superoxide dismutase activity is high in the rabbit and guinea pig corneal epithelium, whereas in the pig corneal epithelium the activity is low and in the bovine corneal epithelium the activity is nearly absent. In contrast, glutathione peroxidase activity is high in the bovine, pig and rabbit corneal epithelium, whereas in the guinea pig corneal epithelium the activity is low. Prooxidant enzymes reveal high xanthine oxidoreductase/xanthine oxidase activity in the rabbit corneal epithelium and much lower activities in the guinea pig and bovine corneal epithelium. In the pig corneal epithelium the activity is absent. In conclusion, results demonstrate substantial variations in enzyme activities. Further studies are necessary to elucidate whether differences in activities might influence the individual susceptibility to oxidative stress-mediated ocular toxicity. At present our study may offer useful information regarding the activities of antioxidant and prooxidant enzymes in various animal species when corneal epithelial cells are choosing for ocular research.

623

**Identification and Characterization of a Novel Lysophosphatidylcholine Acyltransferase in Alveolar Type II Cells**

X. Chen,[1] B. A. Hyatt,[2] J. M. Shannon,[2] R. J. Mason[1]; [1]Medicine, National Jewish Medical and Research Center, Denver, CO, [2]Pulmonary Biology, Cincinnati Children's Hospital, Cincinnati, OH

Pulmonary surfactant is a complex of lipids and proteins produced in alveolar type II cells. Surfactant provides the low surface tension at the air-liquid interface and prevents alveolar collapse during expiration. Pulmonary surfactant is composed predominantly of phospholipids (~ 85%). Lysophosphatidylcholine (lysoPC) acyltransferase is thought to play a critical role in surfactant dipalmitoylphosphatidylcholine (DPPC) synthesis. However, the acyltransferase involved in DPPC synthesis has not yet been identified. Methods: A rat cDNA clone (R1) was identified in the NCBI data base by its sequence homology to a murine putative acyltransferase that is specifically expressed in the developing lung. The full length R1 gene was amplified by PCR from cDNA of rat alveolar type II cells, resulting in a 1.6 kb product. The R1 gene was subcloned into a mammalian expression vector and transfected into 293 cells and COS-7 cells. The recombinant R1 protein was assayed for lysophospholipid acyltransferase activity by measuring the incorporation of radiolabeled acyl moieties of acyl-CoA ( acyl donors) into phospholipids. Results: The R1 gene predicts a 534 amino acid protein of ~ 59 kDa, which contains a transmembrane domain and an acyltransferase (PlsC) domain. The R1 acyltransferase expressed in 293 cells and COS-7 cells increases lysoPC acyltransferase activity. The recombinant enzyme shows a clear preference for palmitoyl-CoA as the acyl donor. Furthermore, keratinocyte growth factor ( KGF) increases the mRNA expression of R1 acyltransferase 8 fold in rat type II cells, and the expression of R1 decreases markedly when type II cells were cultured on plastic to become type I-like cells. Conclusion: The R1 acyltransferase likely plays an important role in biosynthesis of surfactant phospholipids. The elucidation of R1 gene's regulation will increase our

understanding of the control of surfactant lipid synthesis.

624

**Stretch-Induced Exocytosis of Discoidal Vesicles in Bladder Umbrella Cells is Modulated by Tyrosine Kinase Activity**

E. M. Balestreire, G. Apodaca; Department of Medicine, Renal-Electrolyte Division, University of Pittsburgh, Pittsburgh, PA

The mucosal surface of the bladder forms an impermeable barrier that must accommodate changes in urine volume as the bladder fills and empties. At the cellular level, this is accomplished by the dynamic addition and removal of membrane from the apical surface of the umbrella cell layer. An important stimulus for membrane turnover in umbrella cells is bladder filling; however, the mechanotransduction pathways that lead to changes in exocytosis and endocytosis are not known. Tyrosine phosphorylation plays an important role in transducing mechanical stimuli into downstream cellular events in other cell types including vascular endothelial cells, keratinocytes, kidney proximal tubule cells, and osteoblasts. This study examines the hypothesis that tyrosine kinases are an integral part of the mechanotransduction pathway that leads to exocytosis of discoidal vesicles in the filling bladder. A modified Ussing chamber was used to monitor bladder uroepithelium capacitance, a measure of surface area, upon stretch stimulus. In control bladder tissue, filling induced a 50% increase in surface area over 5 hours. Addition of the broad-spectrum tyrosine kinase inhibitor genistein significantly reduced this response to ~25% over 5 hours. The epidermal growth factor receptor (EGFR) inhibitor AG-1478 also attenuated filling-induced increases in capacitance. Specific inhibitors of tyrosine kinases PDGFR, Src, and Jak2, which are known to be important for mechanotransduction in other cell types, caused no inhibition of filling-induced exocytosis. These studies suggest that tyrosine kinases, particularly EGFR, may be important players in the mechanotransduction pathway found in bladder epithelial cells. The exploration of tyrosine kinase activity in the stretch-induced response of bladder tissue will further our understanding of cellular responses to mechanical stimuli, while providing insights into the normal physiology of bladder accommodation of urine.

625

**BMP Signaling is Essential for the Proper Terminal Differentiation of Intestinal Secretory Lineage in Mice**

B. A. Auclair,[1] Y. Benoit,[1] Y. Mishina,[2] D. L. Gumucio,[3] N. Perreault[1]; [1]Anatomy and Cell Biology, University of Sherbrooke, Fleurimont, PQ, Canada, [2]Environmental Disease & Medicine Program, National Heart Lung and Blood institute, Research Triangle Park, NC, [3]Cell and Developmental Biology, University of Michigan, Ann Arbor, MI

**BACKGROUND**: Bone morphogenetic proteins (BMPs) are morphogenes known to regulate numerous cell processes in various tissues. In the intestine, the BMPs are primary produced by the mesenchymal compartment. These factors can activate their signaling pathways following a paracrine or autocrine route. Recent publications have shown links between BMPs signaling and colorectal carcinogenesis. However, the potential effects of this cascade on other important cell functions in the gastrointestinal tract have not yet been explored. **AIM:** To investigate the paracrine role of BMPs signaling during intestinal epithelial cell fate. **METHODS AND RESULTS**: With the use of the Cre/loxP system, we generated a mouse with BMPR1A receptor exclusively deleted in the gut epithelium by crossing floxed *BMPR1A* mice with the Villin-Cre line. Histology analysis showed that the intestine of *Villin-Cre/BMPR1A*$^{loxP/loxP}$ mice displayed abnormal epithelial morphology with elongated villi and multiplication of the crypt units. BrdU incorporation in adult mice revealed an increased number of proliferating cells in mutant mice. The proliferating cells were not confined to the bottom of the crypt but were spread throughout the crypt. Chromagranin A immunostaining showed a statistically significant increase of the number of enteroendocrine cells in the in *Villin-Cre/BMPR1A*$^{loxP/loxP}$ mice. The number of goblet and Paneth cells was not significantly changed in the mutant animals. However, goblet cells were consistently smaller in the mutant mice as seen in Alcian blue staining. Electron microscopy studies confirmed the reduction in size of the goblet cells. Moreover, immunostaining with an anti-lysosyme antibody suggested a reduction in Paneth cell secretory granule content in *Cre-Villin-Cre/BMPR1A*$^{loxP/loxP}$ mice. **CONCLUSION:** Altogether, these results strongly suggest that paracrine BMPs signaling might play an important role in the terminal differentiation of intestinal secretory cell type.

**New Molecular Markers of Human Skin Ageing**

M. Dumas, M. Bonnet Duquennoy, C. Heusele, E. Noblesse, R. Kurfurst, S. Schnebert, F. R. Bonte; LVMH RECHERCHE, Saint jean de braye, France

Skin ageing is mainly due to ultraviolet radiation and oxidative stress leading to modification of its biophysical properties. Studying photoexposed and photoprotected skin biopsies from young and aged women, it has been found that a specific zone, composed of the basal layers of the epidermis, the dermal epidermal junction and the superficial dermis, is the major target of ageing and reactive oxygen species. We showed that this zone named aging responsible interface is characterized by significant variations at a transcriptional and /or protein levels of integrin B1, B4, cytokeratin1, hyaluronic acid, aquaporin 3, tyrosinase, TRP1, p63, p73, type I, III, IV and VII collagens, type 1 laminin, fibrillin, elastic fibers, MMP1, MMP9, TIMP1, PDGF, Chondroitine-4 sulfate and hyaluronate. Skin ageing being mainly characterized by a thinning of the epidermis and loss of its defense and biomechanical properties we decided to focus on epidermal homeostasis and protective mechanisms. Using skin-dedicated cDNA microarray on human keratinocytes (oligosorbent array technique) we found that 24 hours H2O2 treatment downregulates p63, p73 transcription factors known to be involved in the control of the cell cycle regulation and turnover of the epidermis. A natural mixture containing labdane diterpenoids has been found to significantly increase p 63, p73 cell cycle regulators and also the expression of protective thioredoxin genes.

627

**Overexpression of CRABPI in the Epithelial Suprabasal Layer Affects the Proliferation of Epithelial Basal Layer Cells in Retinoic Acid Topically Treated Mouse Skin**

X. Tang; Pharmacology, Medical College of Cornell Univ., New York, NY

CRABPI is a cellular retinoic acid binding protein, and its effects on the physiological functions of retinoic acid are not fully understood. We investigated whether overexpressed CRABPI could influence the actions of retinoic acid in transgenic animals. We specifically targeted CRABPI to the suprabasal layer of the mouse epithelium through the use of the keratin 10 (K10) promoter. CRABPI mRNA was highly expressed in the skin of one week old transgene positive mice as compared to transgene negative mice of the same age. A much higher level of CRABPI protein was

detected in the epidermis of adult, transgene positive mice than in transgene negative mice of the same age. Overexpression of CRABPI did not cause significant morphological abnormalities in adult mouse skin. However, ectopically overexpressed CRABPI in the suprabasal layer enhanced the thickening of the epidermis induced by topical retinoic acid treatment (10 _M, 400 _l for 4 days). It has been reported that the epidermal basal cell proliferation is stimulated by the heparin-binding EGF-like growth factor secreted by retinoic acid activated suprabasal layer cells (Xiao et al., 1999). Our results indicate that a high level of CRABPI in suprabasal layer cells enhances the physiological functions of retinoic acid. Xiao, J. H., Feng, X., Di, W., Peng, Z. H., Li, L. A., Chambon, P. and Voorhees, J. J. (1999). Identification of heparin-binding EGF-like growth factor as a target in intercellular regulation of epidermal basal cell growth by suprabasal retinoic acid receptors. EMBO J 18, 1539-48.

**Autocrine Crosstalk in the Response of Human Epithelial Cells to Tumor Necrosis Factor**

K. A. Janes,[1] S. Gaudet,[2] J. G. Albeck,[2] U. B. Nielsen,[3] D. A. Lauffenburger,[4] P. K. Sorger[2]; [1]Department of Cell Biology, Harvard Medical School, Boston, MA, [2]Department of Biology, Massachusetts Institute of Technology, Cambridge, MA, [3]Merrimack Pharmaceuticals, Cambridge, MA, [4]Biological Engineering Division, Massachusetts Institute of Technology, Cambridge, MA

Tumor necrosis factor (TNF) is a cytokine that induces apoptotic and inflammatory responses, which can be antagonized by growth factors such as EGF and insulin. Here we report a quantitative experimental analysis of crosstalk among TNF, EGF, and insulin receptors in human epithelial cells. Using kinase activity assays, quantitative immunoblotting, and antibody arrays, we construct a cytokine-signaling compendium comprised of ~10,000 protein measurements from HT-29 cells treated with multiple TNF, EGF, and insulin combinations. Mining of the compendium data by classifier-based regression reveals that cells respond to TNF both directly, via activated TNF receptor, and indirectly, via autocrine circuits involving transforming growth factor-α (TGF-α), interleukin-1α (IL-1α), and IL-1 receptor antagonist (IL-1ra). The cascade of TNF-induced autocrine cytokines begins within 10-15 min and evolves over 24 hr to play as important a role as TNF itself in controlling cell signaling and fate. Furthermore, these cytokines show an intricate molecular logic: autocrine IL-1α requires the preceding release of TGF-α, and IL-1α signaling is self-limited by the subsequent release of IL-1ra. The cytokine network exists in colon, breast, and lung epithelial cell lines, suggesting that the autocrine cascade is a general regulatory response of epithelia to TNF. We speculate that time-dependent crosstalk of synergistic and antagonistic autocrine circuits serves to link cellular responses to the local environment during inflammation.

**Amino-terminal TIG3 Truncation Mutants Associate with Type 1 Transglutaminase and Induce Keratinocyte Cell Death**

R. Jans, M. T. Sturniolo, R. L. Eckert; Physiology & Biophysics, Case Western Reserve University, Cleveland, OH

Type 1 transglutaminase (TG-1) is a plasma membrane-anchored protein-protein crosslinking enzyme that is responsible for assembly of the cornified envelope during epidermal keratinocyte differentiation. We recently described TIG3, a low molecular weight, membrane-associated protein, as a TG-1 activator protein in keratinocytes. We also demonstrated that the carboxy-terminal membrane-anchoring domain is required for TIG3 associated cell death. In the present study, we examine the role of the TIG3 amino-terminus. Similarly to full-length TIG3(1-164), expression of the N-terminal TIG3 mutant, TIG3(41-164), causes cell death. Interaction of the TIG3(41-164) with TG-1 was identified by co-immunoprecipitation. In addition, immunoblot analysis revealed high molecular weight forms of TIG3(41-164) in TIG3(41-164) expressing keratinocytes. Formation of these structures is inhibited by treatment with monodansylcadaverine, a competitive transglutaminase substrate, suggesting that TIG3(41-164) is a TG-1 substrate. These findings suggest that TIG3(41-164) promotes keratinocyte cell death by interacting with, and activating, TG-1, and suggest that the N-terminal amino-acids of TIG3 are not required for this function. In addition, these findings indicate that TIG3(41-164) can also serve as a TG-1 substrate. Additional studies show that amino-terminal mutants including TIG3(100-164), TIG3(112-164), and TIG3(124-164) also promote cell death. These findings suggest that the TIG3 amino terminus is not required for TIG3 cell death functions.

**How Do Keratinocytes Respond to Mechanical Stress ? A Transcriptomal Analysis**

O. Duverger,[1,2] M. Moreau,[1,2] M. Bonnet-Duquennoy,[1] S. Schnebert,[1] C. Nizard[1,2]; [1]R&D LVMH Parfums et Cosmetiques, Saint Jean de Braye, France, [2]INSERM U505, Paris, France

The skin is subjected to various strains. Although several studies have focused on the response of dermal fibroblasts to mechanical stress, the response of keratinocytes to strain is poorly documented. We used the cDNA microarray technology to analyze the response of keratinocytes to stretching. HaCaT cells were cultured on a flexible surface and subjected to cyclic stretching. Their transcriptome was analyzed at different times after the beginning of the treatment. This kinetic analysis allowed to identify early and late mechano-responsive genes, including epidermal markers, adhesion molecules, extracellular matrix components, growth factors, transcription factors, genes involved in signal transduction, in cell metabolism, in inflammatory response, in apoptosis and in cell cycle regulation. These results were confirmed by real-time RT-PCR, for a set of selected genes. Bioinformatics analyses led to the identification of pathways involved in the response of keratinocytes to mechanical stress. In short, keratinocytes subjected to cyclic stretching tend to proliferate, to modify their adhesion properties and to change the composition of their extracellular matrix. Moreover, several corneocyte markers are strongly up-regulated, suggesting an activation of late steps of keratinocyte terminal differentiation, as well as a modification of the biomechanical properties of the stratum corneum. These results will be of great interest for the understanding of skin behaviour in response to strain, in normal and pathological conditions.

**Hemoglobin Genotype-dependent Erythrocyte Membrane Potential Correlates to Innate Protection Against Severe Malaria**

F. Tokumasu,[1] J. A. Dvorak[2]; [1]Laboratory of Malaria and Vector Research, National Institutes of Health, Rockville, MD, [2]National Institutes of Health, Rockville, MD

Individuals carrying mutant hemoglobin (Hb) genotypes such as HbC and HbS display innate protection against severe malaria. HbC erythrocytes

age more rapidly than normal erythrocytes with an increase of hemichrome on the cytoplasmic side of the membrane as well as high level of band 3 aggregations. For example, Plasmodium falciparum-infected HbC erythrocytes display larger 'knobs' than parasitized HbA erythrocytes, and decreased endothelial cytoadherence. However, the critical mechanisms responsible for these abnormalities have not been elucidated. One possibility is that physical-chemical features reflected in the lateral membrane organization of lipids and membrane proteins differ between normal and abnormal Hbs. If this premise is correct, the differences should be reflected in the erythrocyte zeta potential as it is an indirect measure of membrane surface potential which can be modulated by variations in membrane proteins and/or lipids as well as exogenous proteins such as immunoglobulins. Homozygous HbA (AA) and HbC (CC) show zeta potentials of -15 and -12 mV, respectively. CC erythrocyte zeta potential distributions also have a longer tails containing higher zeta potential values, implying that various degrees of membrane abnormalities exist in CC erythrocytes. Moreover, aged AA erythrocytes also showed ~1.5 mV higher zeta potential than younger erythrocytes. This implies that CC erythrocytes are prematurely aged but at a higher rate than AA erythrocytes. Furthermore, both P. falciparum-infected AA and CC erythrocytes also show 1-2 mV higher zeta potentials than non-parasitized erythrocytes, indicating that a malaria infection modifies the membrane zeta potential. In contrast, only minor zeta potential differences were found between AA and SS erythrocytes, despite the markedly aberrant shapes induced in SS erythrocytes. Our results demonstrate for the first time that a relationship exists between innate protection against severe malaria and membrane-related physical properties of the erythrocytes.

632

**The Avian Malaria Parasite *Plasmodium gallinaceum* Modifies the Surface Topography of Infected Erythrocytes**

T. Arie,[1] D. W. Dorward,[2] J. A. Dvorak[1]; [1]LMVR, NIAID, Rockville, MD, [2]NIAID/Rocky Mountain Laboratories, Hamilton, MT

In humans, a *Plasmodium falciparum* infection induces knob-like protrusions on the erythrocyte surface. Knobs begin to appear at the late ring stage of the parasite's development. As the intraerythrocytic cycle of malaria progresses the knobs are distributed over the surface of the erythrocyte and the total number of knobs per unit area increases linearly as the parasite matures. These knobs cause the adherence of infected erythrocytes to capillary endothelia as well as other erythrocytes resulting in severe pathologic sequaelae. In contrast to *P. falciparum*, we found by a combination of wide-field fluorescence and atomic force microscopy that the infection of avian erythrocytes by *P. gallinaceum* results in the appearance of furrow-like structures on the infected erythrocyte surface; uninfected erythrocytes do not show this feature. Furthermore, these furrows appear on the surface at almost the same developmental stage of the parasite as do the knob-like structures induced by *P. falciparum*. To further investigate this phenomenon, we utilized scanning and transmission electron microscopy to determine if it was in any way analogous to the knobs formed on infected human erythrocytes by *P. falciparum*. We found that the furrows arise from beneath the erythrocyte membrane, implying that they are probably associated with cytoskeletal components of the erythrocyte membrane. Our data demonstrate that surface modifications resulting from a malaria infection are not restricted to knob-like structures; malaria-induced surface modifications may take other forms. The resolution of this phenomenon could help in our general understanding of the intraerythrocytic cycle of this medically important parasite.

**Unexpected Metabolic Pathways in the Apicoplast and Mitochondrion of Toxoplasma gondii**

D. Soldati,[1] J. Limenitakis,[1] L. Kwok,[1] B. Foth,[1] P. Pino,[2] R. Schepers[2]; [1]Microbiology and Molecular Medicine, CMU, University of Geneva, Geneva, Switzerland, [2]Biological Sciences, Imperial College London, London, United Kingdom

The non-photosynthetic plastid-like organelle indispensable for the parasite survival is the site of several anabolic pathways including fatty acid, isoprenoids, iron-sulphur cluster and some steps of the heme biosynthesis. Most enzymes that are active inside the apicoplast are encoded by the nuclear genome and targeted to the organelle via the endoplasmic reticulum courtesy of a bipartite amino-terminal-recognition sequence. The extensive metabolic activities of the apicoplast impose a high demand for antioxidant protection. Like most aerobic eukaryotic cells, Toxoplasma possesses mitochondrially targeted SODs and peroxidases to safely dispose of oxygen radicals that are generated by cellular respiration and metabolism. Additionally, a subset of those enzymes is shared between the two organelles by an unusual mechanism of bimodal targeting. TgSOD2 and the thioredoxin-dependent peroxidase TgTPX1 exhibit a bipartite N-terminal targeting sequence similar to conventional apicoplast-targeting, however the nature of the signal peptide influences the destination to both the mitochondrion and the apicoplast. This phenomenon of bimodal targeting is not restricted to enzymes involving in the detoxification of radical oxygen species but also extends to other classical metabolic enzymes such as the tricarboxylic cycle member aconitase. In addition to a glyceraldehyde-3-phosphate dehydrogenase, the presence of aconitase and isocitrate dehydrogenase in the plastid organelle are likely to produce the reducing power necessary for the metabolic activities. Furthermore, aconitase also contributes to the 2-methylcitric cycle, a pathway known to use the catabolism of amino acids to generate pyruvate in bacteria and fungi. Interestingly, only the coccidians but not the piroplasmida or haemosporida have acquired the complete set of genes involved in this pathway by lateral transfer (PrpE, C, D and B). The importance of this pathway has carbon source for this obligate intracellular parasite are under investigation.

634

**Disruption of Host Microtubule Cytoskeleton and Centrosome Delocalization by Intracellular *Toxoplasma***

J. D. Romano, N. Bano, I. Coppens; Molecular Microbiology and Immunology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

*Toxoplasma gondii*, an obligate intracellular parasite, actively invades mammalian cells forming a parasitophorous vacuole (PV) from which host plasma membrane proteins are excluded. The PV of *Toxoplasma* exhibits a steady-state distribution, appearing stationary in the perinuclear region of host cells. First, we wanted to determine if the centripetal migration of *T. gondii* inside cells involves host microtubules, and second to explore if the PV perinuclear localization alters the global architecture of the host cytoskeleton. Live cell imaging along with time-lapse confocal microscopy reveals that the parasite moves directionally towards the host nucleus within 30-min and is associated with host microtubules. However, host microtubules are not involved in the parasite intracellular locomotion and host motor proteins (e.g. dynein and kinesin) do not associate with the PV. As the parasite approaches the nucleus, host microtubules appear to extend towards the *Toxoplasma* PV, wrapping around the PV and completely surrounding each individual vacuole. The microtubule overcoating of the PV is initiated at the host nuclear surface about 4-h post-infection and becomes more prominent as parasite division proceeds. Early on, the PV is randomly localized with regards to the host microtubule-

organizing center (MTOC). The PV membrane rapidly forms long extensions supported by host microtubules towards the host MTOC. This results in delocalization of the MTOC from the host perinuclear region to the PV and a stable anchorage of the MTOC to the PV membrane 24-h post-infection. In conclusion, the perinuclear localization of the PV followed by the rearrangement of the host microtubule network, most likely through the usurpation of the MTOC, may allow the parasite to manipulate host membrane-bound organelle trafficking, and thereby to scavenge nutrients.

635

### *Toxoplasma gondii* βCOP Localization and Interactions During Infection

S. S. Smith, J. Moran, K. M. Hager; Biological Sciences, University of Notre Dame, Notre Dame, IN

*Toxoplasma gondii* is the obligate intracellular protozoan parasite that causes Toxoplasmosis in immunocompromised individuals. *T. gondii* has three unique invasion organelles and a residual chloroplast organelle, the apicoplast. Since protein secretion plays an essential role in invasion and maintenance of infection, we are characterizing proteins implicated in regulating protein secretion. In particular, we are studying *Toxoplasma gondii* β-COP like protein (*Tg*βCOP). βCOP has been shown to be involved in protein transport in the early secretory pathway and more recently has been implicated in a variety of protein-protein interactions. Immunofluorescence assays (IFA), immunoprecipitation (IPs), and bioinformatic studies support both novel and conserved roles for *Tg*βCOP. Bioinformatic analysis of *Tg*βCOP reveals a novel C-terminal sequence unique to Apicomplexan parasites, indicating an Apicomplexan specific function. We expect that this novel sequence is either responsible for the differential localization of *Tg*βCOP and/or it serves as a site for a novel protein-protein interaction. In support of the latter hypothesis, IP analysis indicates that *Tg*βCOP interacts with a calcium sensitive molecule. IFA data supports this interaction revealing that *Tg*βCOP localization is sensitive to changes in pH and calcium. This is noteworthy given that a calcium surge in the parasite precedes invasion of the host cell. After invasion and establishment of infection, *T. gondii* parasites replicate asexually. Therefore it is significant that 24 hours after infection ~90% of dividing parasites shows that TgβCOP not only associates with the Golgi (as expected) but also encircles the apicoplast. Based on these results, we hypothesize that *Tg*βCOP has another function besides its role in Golgi to ER retrograde transport. Specifically, during the course of the lytic cycle, we expect that *Tg*βCOP is able to function in transport of materials either to or from the apical organelles and the apicoplast during parasite biogenesis.

636

### Implication of TGF- beta on *Trypanosoma cruzi* infection

M. C. Waghabi,[1] L. M. Lima,[1] W. M. Degrave,[1] M. N. C. Soeiro,[2] M. Keramidas,[3] S. Bailly,[3] J. Feige,[3] T. C. AraújoJorge[2]; [1]Biochemistry and Molecular Biology, Fiocruz, Rio de Janeiro, Brazil, [2]Ultra Structure and Cell Biology, Fiocruz, Rio de Janeiro, Brazil, [3]EMI 0105, Department of Molecular and Structural Biology, INSERM, Grenoble, France

Fibrosis is one of the most important characteristics of the Chronic Chagasic Cardiomyopathy and the anti-inflammatory cytokine, TGF- beta, plays a central role in the development of fibrosis by regulating the synthesis of extracellular matrix. In the present work, we studied the possible role of TGF- beta as an inductor/ regulator agent of the chagasic cardiac remodeling, especially fibrosis. Our data regarding the chronic chagasic patients indicated an association between TGF- beta and fibrosis development. Furthermore, we found important alterations in the pattern of Cx43 distribution in chagasic patients heart cells and within cardiomyocytes cell cultures incubated with exogenous TGF- beta, which could be related to the altered impulse conduction and arrhythmias in the heart. As TGF- beta has been concerned in the invasion of host cells by *T. cruzi*, we next studied the parasite ability to activate host TGF- beta. We observed that *T. cruzi* is able to activate latent TGF- beta in a dose-response manner being also temperature-dependent. Moreover, we observed that *T. cruzi* was able to uptake host TGF- beta, to stock it during intracellular proliferation and possibly use it as a signaling mediator to trigger differentiation into trypomastigotes. In a general context, the *T. cruzi* ability to accumulate and activate TGF- beta could be related to different mechanisms directly or indirectly involved in the development of Chagas disease. Our data suggest that the presence of TGF- beta in the heart can collaborate in the fibrosis formation and arrhythmias reported during the chagasic cardiomyopathy besides contributing for the maintenance of the parasite load in the host tissues.

637

### *Giardia lamblia* Adhesive Force is Insensitive to Surface Treatments

W. R. Hansen,[1] S. C. Dawson,[2] W. Z. Cande,[2] D. A. Fletcher[3]; [1]Biophysics, UC Berkeley, Berkeley, CA, [2]MCB, UC Berkeley, Berkeley, CA, [3]Bioengineering, UC Berkeley, Berkeley, CA

*Giardia lamblia*, a protozoan parasite of the small intestine, causes the gastrointestinal disease giardiasis. *Giardia* adhere to microvilli of epithelial cells in the host small intestine, but the exact mechanism of cellular attachment is unknown. It is likely that attachment and virulence are closely linked by the requirement that trophozoites withstand the periodic pressure of peristalsis. Adhesion of *Giardia* is thought to be mediated primarily by the ventral disc, a 7μm-diameter spiral of microtubules and associated proteins located on the anterior portion of the cell, but the magnitude and mechanism of adhesion is unknown. In this study, we used a centrifuge-based force measurement technique to quantify attachment forces *in vitro* to a variety of surface treatments. In comparison to clean glass surfaces, we found no significant differences in the detachment forces of cell populations from positively charged poly-lysine, hydrophobic tridecafluoro tetrahydrooctyl trichlorosilane, or inert polyethylene glycol (PEG) coated glass. Our results indicate that an attachment mechanism based solely on specific (ligand-mediated) binding is not used by cells in culture and that a mechanism relying solely on electrostatic charge is unlikely. Ultimately, a better understanding of attachment mechanism may aid in the development of specific methods for inhibiting adhesion as a treatment of *Giardia* infections.

638

### Analyze of *Giardia lamblia*-Host Cell Interaction

A. Gadelha, R. Travassos, L. Monteiro-Leal; Department of Histology and Embryology, State University of Rio de Janeiro, Rio de Janeiro, Brazil

*Giardia lamblia* is a flagellated protozoan, which is the causative agent of giardiasis. This cell exerts its parasitism adhering to the host intestinal epithelium. Trophozoites present stable microtubular structures in their cytoskeleton, such as flagella and ventral disc, which participate in the locomotion and adhesion of the cell. In order to understand the dynamic process related to the interaction between *G. lamblia* and intestinal cells, techniques such as video-microscopy have been used by our group. The observations of *Giardia* adhesion, body movements and morphology are allowing us to analyze the effects of several chemicals agents, such as metronidazole and furazolidone, in the attachment of trophozoites to host

cell. We have been using the following methodology: parasites are cultivated in TYIS-33 medium and intestinal cell are grown in DMEM medium. After the formation of monolayer by IEC-6, the parasites are added to the culture medium of these cells, in the presence or absence of drugs. After 24h of treatment, furazolidone showed a reduction of 80% in the adherence of *Giardia*, while metronidazole showed a reduction of only 60%, in the same type of analysis. By video-microscopy, we observed that after 6h and 24h of incubation with metronidazole, the trophozoites showed major modifications in the dorsal surface, despite the fact that some parasites were still able to adhere to the intestinal cells. The parasites treated with furazolidone for a period of 6h, showed slight modifications in their surface. However, after 24h of treatment of the co-culture, the majority of the cells loses their adherence to intestinal cells and was observed without motion in the supernatant. The data obtained indicated that furazolidone affects more the adhesion of the protozoon than its growth pattern, indicating that, this drug is more effective in reduce the attachment then metronidazole.

639

**Charcterization of the Receptor-binding Domains of *Trichomonas vaginalis* AP65 Adhesin**

A. F. Garcia, J. F. Alderete; Microbiology, UTHSCSA, San Antonio, TX

*Trichomonas vaginalis* is an amitochondriate protist responsible for the number one, non-viral sexually transmitted disease. The ability of trichomonads to cytoadhere to vaginal epithelial cells (VECs) is preparatory to successful infection of women. *T. vaginalis* specifically binds to host VECs via the surface expression of at least four adhesin proteins (AP65, AP351, AP33 and AP23). In this work, we focus our studies on determining the binding epitope of the prominent AP65 adhesin. Based on previous published data showing the interacting domains with antibodies generated against AP65, we subcloned different overlapping fragments of AP65 in a pET26b (+) vector containing a C-terminal His-Tag for purification. Cloning of the fragments was verified by PCR. Expression in *Escherichia coli* was then achieved by IPTG induction. The expressed recombinant subcloned proteins were confirmed by detection in nitrocellulose blots after SDS-PAGE and blotting using both specific monoclonal and polyclonal anti-AP65 antibodies. Then each recombinant protein was tested for binding activity using an established host cell binding assay. Furthermore, synthetic overlapping 25-mer peptides containing the N-terminal region of AP65 were used to conduct binding inhibition studies. The data suggest that the cell surface interactive domain of AP65 resides on the N-terminal residues.

640

***Trichomonas vaginalis* Genes Induced upon Contact with Human Vaginal Epithelial Cells**

A. S. Kucknoor, V. Mundodi, J. F. Alderete; Microbiology, UT Health Science Center, San Antonio, TX

Host parasitism by *Trichomonas vaginalis* is complex, and the adhesion to vaginal epithelial cells (VECs) by trichomonads is preparatory to colonization of the vagina. The objective of this study was to identify genes that are induced due to signaling of trichomonads following adherence. In order to identify the genes that are up-regulated, we constructed a subtraction cDNA library enriched for differentially-expressed genes from the parasites that were in contact with the host cells. Thirty randomly selected cDNA clones representing the differentially regulated genes upon initial contact of parasites with host cells were sequenced. Several genes encoded for functional proteins with specific functions known to be associated with colonization, such as adherence, change in morphology, and gene transcription and translation. Interestingly, genes unique to trichomonads with unknown functions were also up-regulated. Semi-quantitative, reverse transcription polymerase chain reaction (RT-PCR) confirmed expression of select genes. Increased amount of protein was demonstrated by immunoblotting with monoclonal antibody. Finally, we showed by RT-PCR the transcriptional regulation of some genes by iron. To our knowledge, this is the first report addressing the differential regulation of *T. vaginalis* genes immediately upon contact with VECs.

641

**Antisense RNA Inhibition of *Trichomonas vaginalis* AP33 Adhesin Gene Expression**

V. Mundodi, A. S. Kucknoor, J. F. Alderete; Microbiology, UTHSCSA, San Antonio, TX

*Trichomonas vaginalis* is the causal agent of trichomonosis, the most prevalent non-viral sexually transmitted disease worldwide. The key step in the initiation and establishment of infection is the adherence of the parasite to host epithelial cells. Adherence is known to be mediated by the coordinated expression of surface protein adhesins (AP65, AP51, AP33, and AP23). Earlier, we showed for the first time the antisense RNA-mediated inhibition of AP65 gene expression in *T. vaginalis*. Abolishing AP65 gene expression resulted in poor parasite adherence to host cells. AP33 is known to be another adhesin, and, like AP65, has sequence identity to an enzyme also localized to hydrogenosome organelles involved in energy generation. Therefore, AP33 is another member of a family of trichomonad proteins with functional diversity. In order to validate the adhesin function of AP33 by genetic means, our objective was to establish an efficient transfection system for antisense RNA inhibition and silencing of the *ap33* gene expression. We confirmed the cloning into the vector pBS-*neo* in sense and antisense orientations the gene sequence coding for AP33. This gave the plasmids pBS-*neo*AP33S (sense) and pBS-*neo*AP33AS (antisense). *T. vaginalis* parasites were then successfully transfected with AP33S and AP33AS plasmids, and stable transfectants were selected using G418. PCR amplification of the neomycin gene (*neo*) from the transfectants confirmed the presence of plasmids. Western blot analysis of total proteins from 33AS transfectants showed a significant reduction in the amount of AP33 compared to controls. This successful decreased synthesis of the AP33 adhesin is a critical first step toward confirming at a genetic level the role of this protein in adherence and, therefore, parasite virulence.

642

**Glyceraldehyde-3-phosphate dehydrogenase Synthesized by the Amitochondriate Eukaryote, *Trichomonas vaginalis*, is a Highly Immunogenic Surface Expressed Protein**

T. Chang, J. F. Alderete; Microbiology, UTHSCSA, San Antonio, TX

*T. vaginalis* is a protozoan responsible for the number one, non-viral sexually transmitted disease that is responsible for significant adverse health outcomes for both women and men. Adherence to vaginal epithelial cells is a virulence property that is preparatory to host infection. The surface adhesins are proteins that mediate adherence and are members of multigene families encoding proteins with functional diversity, as the proteins are also enzymes that reside within hydrogenosome organelles. A library of monoclonal antibodies (mAbs) was generated, and mAbs were screened for immunoreactivity towards parasite surface proteins using a whole cell-ELISA. Four mAbs were identified that recognized a cDNA clone

expressing recombinant glyceraldehyde-3-phosphate dehydrogenase (GAPDH). The mAbs detected live organisms by indirect immunofluorescence and reacted with chemically-stabilized trichomonads. Analysis by cell fractionation revealed the protein in the membrane fraction. A sandwich ELISA with immobilized patient serum IgG readily bound recombinant GAPDH protein that was then detected by the mAbs, indicating the immunogenic nature of GAPDH in patients. These data are exciting new findings, and the literature is replete with the functional diversity of GAPDH among microbial pathogens and mammalian cells. This work extends our findings on the surface placement of trichomonad enzymes, and GAPDH may likewise be an important immunogenic virulence factor for *T. vaginalis*.

643

**_Mycoplasma hominis_ Infects Clinical Isolates of _Trichomonas vaginalis_ and Affects Growth Rates and Synthesis of Adhesin and Patient Antibody Responses**

J. F. Alderete, T. Chang; Microbiology, UTHSCSA, San Antonio, TX

The number one, non-viral sexually transmitted infection worldwide is caused by the protist *T. vaginalis*, which is responsible for significant adverse health outcomes for both women and men. Adherence by the parasite to vaginal epithelial cells (VECs) is a virulence property, and one surface protein called AP65 is a prominent adhesin mediating adherence. Our objective was to evaluate the presence of mycoplasma in clinical isolates of *T. vaginalis* and to ascertain whether mycoplasma infection affected properties, such as growth rates and synthesis of AP65. PCR using *M. hominis*-specific primers was optimized on known positive and negative controls, and a 330-bp mycoplasma PCR product was found in 44 of 58 fresh isolates (76 %). Interestingly, supernatants of cultures of mycoplasma-infected trichomonads were cloudy compared to supernatants of cured and/or mycoplasma-free cultures. Pellets of cloudy supernatants were capable of reverting PCR-negative to PCR-positive for mycoplasma detection among organisms, indicating the presence of infectious mycoplasma released into supernatants during growth by infected trichomonads. Sera of 97 of 136 patients (71%) tested positive for the presence of anti-mycoplasma antibody by ELISA and immunoblot, which was in agreement with the PCR analysis. Trichomonads cured of mycoplasma had higher rates of growth compared to mycoplasma-infected, parental isolates. Also, immunoblots showed that cured trichomonads synthesized greater amounts of AP65 adhesin than did infected parasites. Importantly, mycoplasma bound purified AP65, suggesting a mechanism for subverting VEC adherence mechanisms for interacting and possibly invading *T. vaginalis* in vivo. In conclusion, this work supports reports by others on mycoplasma infections of *T. vaginalis* and shows mycoplasma affecting growth rates, synthesis of adhesin and host antibody responses.

644

**Micrornas mediate C parvum-induced Upregulation of Toll-like Receptors In Cholangiocytes**

X. Chen, P. L. Splinter, S. P. O'Hara, N. F. LaRusso; Mayo Medical School, Rochester, MN

Recent studies have demonstrated that microRNA (miRNA)-mediated post-transcriptional gene regulation may be involved in a wide range of essential biological events including host-cell defense responses to microbial infection. Toll-like receptors (TLRs) are an evolutionarily conserved family of cell surface pattern recognition receptors that are key contribute to innate immunity by detecting invading pathogens. Using an *in vitro* model of biliary cryptosporidiosis employing freshly excysted *Cryptosporidium parvum (C. parvum)* sporozoites and a human cholangiocyte cell line, we previously demonstrated that *C. parvum* induces TLR2 and 4 upregulation in cholangiocytes. However, the precise mechanisms resulting in *C. parvum*-induced TLR upregulation remain unclear. Here, we tested the HYPOTHESIS that endogenous miRNA-mediated post-transcriptional regulation may mediates *C. parvum*-induced upregulation of TLRs. Using an *in silico* computer-generated database search approach, we identified several miRNAs that potentially target TLR2 and 4 mRNAs, i.e., miR-9 and miR-337 for TLR2 mRNA and Let-7i for TLR4 mRNA. We next demonstrated expression of miR-9, miR-337 and Let-7i in cultured normal human cholangiocytes by Northern blot and microarray analysis. Moreover, we found that expression of these miRNAs was altered and related to expression of TLR2 and 4 during *C. parvum* infection. Specifically, we designed an anti-sense, 2-methoxy oligonucleotide specific to Let-7i, and showed that reduction of Let-7i significantly increased TLR4 protein expression in cultured cholangiocytes by 2.5 Xfold, confirming that a Let-7i-mediated post-transcriptional suppression pathway of TLR4 exists in cholangiocytes. In addition, we found that Let-7i was decreased in cholangiocytes 3 Xfold after exposure to *C. parvum*. Taken together, our data indicate that: i) the machinery for miRNA-mediated post-transcriptional suppression of TLR expression exists in cholangiocytes; and ii) this regulatory machinery is altered upon *C. parvum* infection and thus, mediates *C. parvum*-induced upregulation of TLRs in cholangiocytes.

645

**The Interaction Between Opportunistic Parasitic Amoebae and Extracellular Matrix Glycoproteins**

B. Rocha-Azevedo,[1,2] G. A. Cabral,[2] F. C. Silva-Filho,[1] F. Marciano-Cabral[2]; [1]Instituto de Biofisica Carlos Chagas Filho, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil, [2]Dept of Microbiology and Immunology, Virginia Commonwealth University, Richmond, VA

Amoebae of the genera *Acanthamoeba* and *Balamuthia* are encountered worldwide. Some species can cause life-threatening infections, mainly in immunocompromised individuals. *Acanthamoeba* spp. are the causative agents of encephalitis, cutaneous lesions, and keratitis. *Balamuthia mandrillaris* is a recently described opportunistic pathogen, which causes encephalitis. The mode that these amoebae cause cytopathogenesis is not known, but it is documented that these protozoa are able to adhere and to destroy mammalian cells. After host cell destruction, it has been postulated that amoebae gain access to a group of biomolecules that are components of the extracellular matrix (ECM) that are important in the progression of protozoan infections. In *Balamuthia* and *Acanthamoeba* infections, they may play a role in the infection process, since these amoebae are invasive microorganisms. The objective of this study was to characterize the interaction of *A. polyphaga*, *A. culbertsoni*, *A. astronyxis* and *B. mandrillaris* with three pivotal ECM glycoproteins (Fibronectin, Laminin-1 and type I Collagen). To quantify these interactions, we performed binding assays using $^{3}$H-radiolabelled amoebae. We observed that amoebae are able to attach to ECM molecules with different avidity (binding on laminin >collagen >fibronectin). We determined that different species of *Acanthamoeba* exert differential specific binding to ECM glycoproteins. *Balamuthia*, which attach poorly in plastic flasks, demonstrate a major increase in attachment when the plastic substratum is coated with Collagen and Laminin. Morphological differences were observed by light and scanning electron microscopy depending on the type of substratum. Numerous lamelipodia were observed for amoebae adhered to laminin, while an increase of acanthapodia was observed for amoebae adhered to collagen and fibronectin. Differential binding to ECM glycoproteins may articulate a mode by which opportunistic amoebae effect

cytopathogenesis. Financial Support: CAPES-MEC (PDEE-BEX: 0158/05-9), CNPq, FUJB-UFRJ, MCT-PRONEX and NIH ( DA 05832, DA 05274).

**Roles of Toll-like Receptor 2 and 4 in In Vitro Response of Macrophages to *Pneumocystis carinii***

C. Zhang, S. Wang, M. E. Lasbury, P. J. Durant, C. Lee; Pathology and Laboratory Medicine, Indiana University School of Medicine, Indianapolis, IN

*Pneumocystis carinii* (*P. jiroveci* for that infects humans) is a major opportunistic fungal pathogen in immunocompromised hosts. The innate immunity to this organism is not well understood. In this study, we showed that normal mouse alveolar macrophages (AMs) respond to *P. carinii* organisms by activating the nuclear translocation of NF-kB, leading to production of proinflammatory cytokines TNF-α and MIP-2. Using gain-of-function studies with transiently transfected HEK293 cells, we found that TLR2, but not TLR4, confers HEK293 cells NF-kB response to *P. carinii*. TNF-α and MIP-2 productions in response to *P. carinii* in mouse alveolar macrophages were inhibited by monoclonal antibody T2.5, which specifically blocks the ligand-binding ability of TLR2. AMs from TLR2-/- mice showed little increase in TNF-α and MIP-2 mRNA levels upon *P. carinii* stimulation, similar to control AMs that were stimulated with only sterile saline. Taken together, these results show that TLR2 plays an important role in the innate immune response to *P. carinii.*

**Gene Expression Profile of the Nematode *Heterodera glycines* Throughout Development**

A. A. Elling,[1] M. Mitreva,[2] X. Gai,[3] M. Dante,[2] J. P. McDermott,[4] T. R. Maier,[4] A. Kalyanaraman,[5] S. Aluru,[5] R. S. Hussey,[6] E. L. Davis,[7] J. P. McCarter,[2] T. J. Baum[4]; [1]Interdepartmental Genetics Program, Iowa State University, Ames, IA, [2]Genome Sequencing Center, Washington University School of Medicine, St. Louis, MO, [3]L.H. Baker Center for Bioinformatics and Biological Statistics, Iowa State University, Ames, IA, [4]Department of Plant Pathology, Iowa State University, Ames, IA, [5]Department of Electrical and Computer Engineering, Iowa State University, Ames, IA, [6]Department of Plant Pathology, University of Georgia, Athens, GA, [7]Department of Plant Pathology, North Carolina State University, Raleigh, NC

The soybean cyst nematode *Heterodera glycines* is an obligate biotrophic plant-parasitic nematode which causes annual soybean yield losses of $800 million in the USA alone. Genomic approaches to characterize the gene expression profile of parasitic nematodes open new ways to identify genes that are central to successful parasitic relationships and that might be exploited as nematicide targets. To better understand the developmental biology of this nematode species, we generated and analyzed 20,109 5' expressed sequence tags (ESTs) covering all major life stages (eggs, pre-parasitic J2, parasitic J2, J3, J4, adult females). The transcripts were grouped into 7,734 contigs and 6,883 clusters, possibly representing 36% of all *H. glycines* genes assuming approximately 19,000 genes as in *Caenorhabditis elegans*. The GC content of the EST set studied was 49% with more than 10 million total nucleotides. To classify the ESTs by function, we used the Gene Ontology hierarchy as well as the KEGG database. Sequence alignments revealed *H. glycines* genes with similarity to *C. elegans* genes for which known RNAi phenotypes exist. Furthermore, we were able to identify putative nematode-specific and *Heterodera*-specific genes as well as genes that might have been acquired through horizontal gene transfer from prokaryotes. In summary, this dataset greatly increased the available sequence information for this important nematode species and reveals for the first time a gene expression profile throughout development for a plant-parasitic nematode.

**Association of Rab GTPases with the *Salmonella*-Containing Vacuole**

A. C. Smith,[1,2] X. Jiang,[2] J. T. Cirulis,[3,4] W. D. Heo,[5] T. Meyer,[5] J. E. Casanova,[6] M. A. Scidmore,[7] J. H. Brumell[1,2]; [1]Department of Molecular and Medical Genetics, University of Toronto, Toronto, ON, Canada, [2]Infection, Immunity, Injury and Repair, Hospital for Sick Children, Toronto, ON, Canada, [3]Department of Biochemistry, University of Toronto, Toronto, ON, Canada, [4]Cardiovascular Research, Hospital for Sick Children, Toronto, ON, Canada, [5]Department of Molecular Pharmacology, Stanford University, Stanford, CA, [6]Department of Cell Biology, University of Virgina School of Medicine, Charlottesville, VA, [7]Department of Microbiology and Immunology, Cornell University, Ithaca, NY

The intracellular pathogen *Salmonella enterica* serovar Typhimurium (*S*. Typhimurium) resides in a membrane bound vacuole, the *Salmonella*-containing vacuole (SCV). Previous studies suggest the bacteria modify trafficking of the SCV, acquiring a subset of late endosomal/lysosomal proteins, avoiding fusion with the lysosome, and establishing a niche for replication. Approximately 6-8 hours after invasion, *S.* Typhimurium form filamentous membrane structures from the SCV called *Salmonella*-induced filaments (Sifs). To examine SCV trafficking we studied its interactions with intracellular markers. There are over 60 Rab GTPases, each interacting with effector proteins to coordinate vesicular traffic. We studied the interaction of 44 Rabs with two strains of *S*. Typhimurium: wildtype and a strain (Δ*invA/inv*) that traffics to the lysosome. We looked for co-localization of Rabs with the SCV at various times within three hours of invasion, as well as with Sifs. Many differences were seen between the two strains, one of which being an accumulation of the endocytic recycling marker Rab11 around wildtype bacteria and not Δ*invA/inv*. We determined that the wildtype SCV interacts with multiple regulators of endocytic recycling, and this is required for efficient SCV maturation. Our findings demonstrate the complex and dynamic nature of the SCV and the utility of performing a 'Rab screen' to understand phagosome modulation by intracellular pathogens.

**Development of a Polarized Epithelial Cell Model to Study the Role of Akt/PKB in Salmonella Enterica Interactions with the Intestinal Epithelium**

R. Ireland, O. Steele-Mortimer; LICP, NIAID/NIH, Hamilton, MT

The facultative intracellular pathogen *Salmonella enterica* is a common cause of gastroenteritis. Virulence is dependent on the ability of *S. enterica* to invade intestinal epithelial cells, which is mediated by a type III secretion system (TTSS) encoded on *Salmonella* Pathogenicity Island 1 (SPI1). Several effector proteins translocated by the SPI1 TTSS promote massive actin rearrangements leading to plasma membrane ruffling and subsequent engulfment of the bacteria. One of these effectors, the inositol phosphatase SopB/SigD, also mediates sustained activation of the pro-survival kinase Akt/PKB. Studies using HeLa cells have demonstrated that SopB-dependent Akt activation delays apoptosis and protects infected

cells from chemical induction of apoptosis. To investigate the role of Akt activation in intestinal epithelial cells we have developed a model using the C2Bbe1 cell line, a clonal derivative of human Caco-2 cells. C2Bbe1 cells grown on collagen-coated filter inserts in defined (serum free) media produce uniform differentiated monolayers with tight junctions and well-differentiated brush border membranes within a few days. We found that *S. enterica* serovar Typhimurium invasion of these cells is SPI1-dependent, involves rapid transient effacement of microvilli and plasma membrane ruffling and is associated with sustained phosphorylation of Akt. A mutant lacking SopB invades C2Bbe1 cells but without inducing Akt phosphorylation. As in HeLa cells, SopB-dependent Akt phosphorylation is associated with decreased caspase-3 activation and protection against camptothecin-induced apoptosis. To further characterize the role of Akt activation in intestinal epithelial cells we used siRNA to selectively deplete the two isoforms, Akt1 and Akt2, which are expressed in epithelial cells. The results suggest that the SopB-dependent pro-survival signal is mediated primarily by Akt2.

**Perturbation of the Endocytic Pathway Affects Expression and Translocation of Salmonella-effector Proteins in Cultured Epithelial Cells**

P. Fuentes, D. Drecktrah, L. A. Knodler, O. Steele-Mortimer; LICP, NIAID/NIH, Hamilton, MT

The ability of *Salmonella enterica* to survive and replicate within host cells is crucial for pathogenesis and is mediated by a number of virulence factors. In particular, two Type III secretion systems (TTSS) translocate effector proteins directly into the host cell. Effectors translocated by the *Salmonella* Pathogenicity Island 1 (SPI1) TTSS mediate invasion of non-phagocytic cells while those translocated by the SPI2 TTSS are required for intracellular survival. Biogenesis of the *Salmonella*-Containing Vacuole (SCV) involves multiple interactions with the endocytic pathway and is mediated by TTSS effectors. However, the nature of these interactions and the intracellular signals that determine TTSS expression and function have not been fully elucidated. Here we have investigated the effect of perturbing the endocytic pathway, by either inhibiting the vacuolar proton pump (vATPase) or depolymerizing microtubules, on the expression of SPI1 and SPI2 genes as well as on effector translocation. Changes in intracellular gene expression were analyzed by quantitative PCR at 0 - 8 h post invasion. In addition, a destabilized green fluorescent protein (GFP)-based assay was used to determine promoter activity in individual intracellular bacteria. To study translocation of SPI1 and SPI2 effectors into the host cell the calmodulin-dependent adenylate cyclase domain (Cya) of the *Bordetella pertussis* cyclolysin was used as a reporter protein. We found that, in infected HeLa cells, the expression profile of *Salmonella* SPI1 and SPI2 genes was significantly affected by perturbation of the endocytic pathway. Furthermore, efficient effector translocation, particularly of SPI2 effectors, was dependent on vATPase activity. These findings are allowing us to better characterize the role of the endocytic pathway in determining intracellular virulence gene expression and SCV biogenesis.

**Helicobacter Pylori Induces a Calcium-dependent Modulation of Actin Cytoskeleton by Activation of Calpain I**

Z. Guo,[1] X. Ding,[1,2] T. Ward,[1] B. Liu,[3] Z. Zhu,[3] X. Yao,[1] A. Shaw[1]; [1]Physiology, Morehouse School of Medicine, Atlanta, GA, [2]Beijing Univ. of Medicine, Beijing, China, [3]Shanghai Institute of Digestive Surgery, Shanghai, China

Helicobacter pylori is one of the most wide-spread bacterial pathogens and implicated in the pathogenesis of gastritis, gastric ulcer, and gastric cancer. Helicobacter pylori targets to gastric glandular epithelial cells and initiates a variety of cellular signaling events to abrogate cell physiology However, the underlying pathogenic mechanisms remain elusive. Our previous demonstration of an inter-relationship between calpain I and ezrin in gastric injury propelled us to examine the possible role of calpain I activation in Helicobacter pylori infection. Here we show that treatment of Helibobacter pylori mobilizes intracellular calcium in cultured gastric parietal cells. The rise in intracellular calcium is contributed by the influx of extracellular pool and the release from the internal store. The elevation of intracellular calcium resulted in an activation of calpain I judged by autolysis of the large subunit of the enzyme and proteolysis of ezrin. This proteolyses were minimized by either pre-treatment of calcium chelator BAPTA or calpain I inhibitor E64, validating the involvement of calcium-dependent proteolysis. Interestingly, Helicobacter pylori-induced calpain I activation induced the reorganization of apex and alterations in cell morphology due to the loss of ezrin. This ezrin-deficient morphological alteration was validated by an ezrin siRNA experiment in which depletion of ezrin resulted in defects in the formation of canalicular apical membranes in gastric parietal cells. Significantly, ectopic expression of ezrin rescued the morphological alteration induced by Helicobacter pylori treatment. We reason that Helicobacter pylori disrupts gastric epithelial cell morphology and physiology by activation of calpain I.

**Co-option of Eukaryotic Lipid Bodies by *Chlamydia trachomatis***

Y. K. Budigi, R. H. Valdivia; Molecular Genetics & Microbiology, Duke University Medical Center, Durham, NC

Lipid bodies (LBs) are ubiquitous lipid-rich organelles found in all eukaryotes. While traditionally LBs were regarded as passive neutral lipid storage organelles, recent studies have revealed that LBs are highly dynamic organelles that are intimately involved in lipid, membrane trafficking and cell signaling. During a screen for proteins from the obligate intracellular bacterial pathogen *Chlamydia trachomatis* that are tropic for eukaryotic organelles, we identified four proteins that are recruited to eukaryotic LBs. *C. trachomatis* resides within a membrane-bound compartment that evades fusion with lytic compartments, yet readily acquires host-derived phospholipids, cholesterol and sphingolipids by mechanisms that are poorly understood. We have found that LBs are recruited to the surface of the chlamydial vacuole and that infection results in proliferation of LBs. Analysis of the LB proteome by 2D-DIGE revealed that >40 proteins were altered during infection. Furthermore, pharmacological inhibition of LB biogenesis results in impaired chlamydial growth. Our findings provide evidence for a novel mechanism of organelle subversion wherein *Chlamydia* recruits LBs and co-opts their function for survival. We propose that *Chlamydia* may use LBs as a non vesicle-mediated pathway for lipid acquisition. Alternatively it is possible that this represents an example of “organelle mimicry” where the chlamydial vacuole is protected from the endolysosomal system by being perceived as an ‘LB’ by the host. Molecular characterization of LBs during *Chlamydia* infection presents a unique opportunity to explore the functions of these understudied organelles.

**A Comparison of Two High-Throughput Assays for FtsZ Inhibitors**

R. Baliga, D. Guo, N. Tomasevic, Z. Jia, E. DeHostos, K. Brejc, R. Sakowicz, S. Lichtsteiner, D. W. Pierce, J. T. Finer; Assay Development, Cytokinetics, South San Francisco, CA

The FtsZ protein from E.Coli plays a critical role in cell division and therefore represents an attractive target for antibacterial drug development. Previously, a filtration based assay using fluorescently labeled FtsZ mutant T65C has been used to identify inhibitors of FtsZ polymerization by Wang et al (1). Here we describe a comparison between two high-throughput homogeneous assays with simpler liquid handling requirements. The assays are based on binding of GTP by FtsZ and its subsequent hydrolysis, which are essential steps in the FtsZ polymerization/depolymerization cycle. The GTP binding assay uses fluorescence polarization to quantitate the extent of binding of a fluorescent GTP analog to FtsZ. The GTPase assay employs an absorbance-based coupled enzyme system to quantitate the amount of GDP released as a function of time. Both assay methods were developed as high-throughput screens and applied to a library of approximately 20,000 small molecules with generally drug-like properties. Using the GTPase, we were able to identify several FtsZ inhibitors of modest potency (<50 uM). The GTP binding assay is more successful for the slow polymerizing FtsZ's from Mycobacterium tuberculosis and Bacillus subtilis. Using light-scattering assays, we found that inhibitors identified from the two assays do have demonstrable effects on the polymerization/depolymerization of FtsZ and may provide useful starting points for lead optimization against this target. ### Modeling Virus Competition Dynamics Within a Single Host

C. L. Ball, D. Coombs; Mathematics, University of British Columbia, Vancouver, BC, Canada

Viruses that cause chronic infections, such as HIV and hepatitis C virus, are genetically highly variable due to a high rate of error during replication. This high rate of mutation allows for the evolution of multiple strains within a host and leads to competition between strains, with only the fittest surviving. Viral fitness can be measured as the expected number of virions produced over the lifetime of an infected cell. A rapidly replicating virus will produce large numbers of virions quickly, but host cell death is increased due to the damaging effects of viral replication. It is natural to assume that the rate of cell death will increase as a function of increasing viral replication. Based on these assumptions, we can find the optimal rate of viral replication.[1] We have developed a mathematical model that allows the virus to mutate within the host, letting the strains vary only in their replication rate. We have found that the system will eventually evolve to the optimal strain, but virus strains that replicate more rapidly than optimally will always dominate during the initial stages of infection. Additionally, during this initial period the viral load reaches an extremely high level. This is important because it has been shown that transmission rates between hosts are highest when the viral load is high. We are extending our model to allow transmission between hosts, while still allowing the virus to evolve within each host. The purpose of our research is to determine which strains are the most effective at transmitting between hosts and to determine the distribution of virus strains within a population. ### Temporal Changes in Macrophage Activation May Mediate Lung Tumor Progression

E. F. Redente, A. M. Malkinson; Pharmaceutical Sciences, University of Colorado Heath Sciences Center, Denver, CO

The accumulation of tumor associated macrophages (TAM) enhances the growth of pulmonary adenocarcinomas. Different TAM phenotypes contribute to establishing a tolerant microenvironment that nurtures tumor growth. Classically activated macrophages are triggered by IFN-γ or lipopolysaccharide to become effector cells whose phenotype is characterized by increased production of NO via expression of inducible nitric oxide synthase (iNOS) and initiation of a Th1 lymphocytic response. IL-4 and IL-13 activate macrophages to an alternative state by upregulating arginase I which decreases NO and initiates a Th2 response which promotes tumor growth. Macrophages are a major source of $PGE_2$ during inflammation, and tumor cells undergo paracrine $PGE_2$ signaling to suppress immune responsiveness and allow tumor development. In contrast, prostacyclin ($PGI_2$) antagonizes lung tumor progression in mice. Immunohistochemical analysis of TAM in urethane-induced pulmonary adenocarcinomas in A/J mice exhibits a temporal activation switch in the macrophage population. Macrophages surrounding uninvolved tissue immunostain for arginase in benign adenomas but not in malignant adenocarcinomas. Macrophages have limited iNOS staining in adenomas but increased their iNOS staining in adenocarcinomas. By western blot analysis, iNOS expression was significantly elevated at both time points in tissue adjacent to the tumors compared to age matched control lungs. Arginase I expression was significantly higher in uninvolved tissue near benign tumors than in control animals, but arginase I expression was reduced near malignant tumors, analogous to what was observed by immunohistochemistry. The pulmonary macrophage MH-S cell line can be manipulated by cytokine exposure *in vitro* to exhibit classical vs. alternative activation and provide a model ideal for studying $PGE_2/PGI_2$ production in lung epithelial cells co-cultured with macrophages. Understanding how tumors manipulate, and in turn are regulated by, the macrophage phenotype is important to experimentally modulating tumor progression. (Supported by CA33497 and CA96133)

### Inhibition of the Siah-1 Ubiquitin Ligase by a Viral Oncogene Up-Regulates β-catenin in B-lymphoma Cells

J. Shackelford,[1] K. Jang,[2] J. S. Pagano[1]; [1]Lineberger Cancer Center, UNC at Chapel Hill, Chapel Hill, NC, [2]Division of Biological Sciences, Pusan National University, Busan, Republic of Korea

As a multifunctional molecule β-catenin plays important role in cellular processes. The protein levels of β-catenin are tightly regulated by the ubiquitin/proteasome system. We provide evidence that two ubiquitin/proteasomal degradation pathways for β-catenin are active in the same B-lymphoma cells: along with the classical GSK3β-dependent destruction machinery, degradation of β-catenin through Siah-1 ubiquitin ligase is functional in these cells. We show that inhibition of Siah-1 by a ligase-inactive mutant, as well as reduction of Siah-1 expression by siRNA, stabilizes and activates β-catenin in B-cells. Moreover, inhibition of Siah-1-dependent ubiquitination abolishes up-regulation of β-catenin by the principal Epstein-Barr virus oncogene - LMP1. Thus we demonstrate the significance of the endogenous Siah-1-dependent ubiquitin/proteasomal pathway for β-catenin degradation in malignant human cells and its regulation by a viral oncogene.

**Vascular Endothelial Growth Factor (VEGF) is Influenced by Hormones of the Sympathetic Nervous System in a Metastatic Prostate Cancer Cell Line**

R. C. Youngblood,[1] N. M. Filipov,[2] P. L. Ryan[1]; [1]Animal and Dairy Sciences, Mississippi State University, Mississippi State, MS, [2]Basic Sciences, College of Veterinary Medicine, Mississippi State University, Mississippi State, MS

Psycho-physiological pathways induced by stress, namely activation of the sympathetic nervous system and subsequent release of epinephrine (E) and norepinephrine (NE) have been recognized to influence pathogenic processes, including cancer. VEGF gene expression is known to be affected by the stress hormones, E and NE in ovarian cancer cell lines. Increased levels of VEGF can be indicative of poorer prognoses in patients with cancer. Thus, the goal of this study was to examine the effects of E and NE on VEGF gene expression in a metastatic prostate cancer cell line. To this end PC-3M cells, stably transfected, with a VEGF-*Luc* reporter gene were seeded ($1.0 \times 10^5$ cells/well) in 6-well plates, and cultured for 24 h in media containing charcoal-stripped fetal calf serum, followed by a further 24 h incubation in serum-free media. Cells were then treated with E or NE in replicates of 6 wells at 0, 0.01, 0.1, 1, and 10 μM under serum-free conditions at 70-80% confluency. Cells were harvested at 6, 12, and 24 h post treatment and relative light units (RLUs) were measured using a luminometer. Experiments were repeated 4 times. E, at 1 and 10 μM concentrations, increased ($p<0.05$) VEGF promoter-driven luciferase activity (1537.88 ± 166.53, 1589.5 ± 166.53 RLUs) over that of controls (1156.59 ± 166.53 RLUs) at 12 h and 1 μM NE increased ($p<0.05$) VEGF promoter-driven luciferase activity (1642.33 ± 133.97 RLUs) over that of controls (1286.25 ± 133.97 RLUs) at 12 h. These findings provide experimental evidence that psycho-physiological stress mediators such as E and NE can directly contribute to an increase in VEGF gene expression in prostate cancer cells. **Fusion with VEGF-C Propeptides Enhances the Biological Activity of VEGF**

S. E. Keskitalo,[1] T. Tammela,[1] T. Karpanen,[1] M. Jeltsch,[1] S. Yla-Herttuala,[2] K. Alitalo[1]; [1]Molecular/Cancer Biology Laboratory, University of Helsinki, Helsinki, Finland, [2]Molecular Medicine Group, University of Kuopio, A.I.Virtanen institute, Kuopio, Finland

The five mammalian vascular endothelial growth factor (VEGF) family members identified to date VEGF, VEGF-B, VEGF-C, VEGF-D, and placenta growth factor (PlGF) are key effectors of physiological and pathological regulation of vasculogenesis, hematopoiesis, angiogenesis, lymphangiogenesis, and vascular permeability. VEGF is a potent growth factor for blood vessel formation and plays an essential role in this process. Full length VEGF-C has been shown to activate VEGF receptor-3 (VEGFR-3) and to induce lymphangiogenesis, while proteolytic removal of the amino- and carboxyterminal propeptides of VEGF-C yields a mature growth factor that is also able to activate VEGFR-2 and stimulate angiogenesis. The biological properties of the propeptides of VEGF-C are poorly known. We have engineered a chimeric growth factor protein, VEGF-CAC, composed of the amino- and carboxyl-terminal propeptides of human VEGF-C fused to the receptor-activating core domain of human VEGF. We found that VEGF-CAC could be precipitated with soluble forms of VEGFR-1, VEGFR-2, neuropilin-1 and neuropilin-2. Correspondingly, VEGF-CAC supported the growth of Ba/F3 cells transfected with chimeric VEGFR-1/Epo or VEGFR-2/Epo receptors, suggesting that it is a functional ligand. For analysis of the effects of VEGF-CAC *in vivo*, we chose to express VEGF-CAC via adenoviruses in the ear skin of immunodeficient mice. Surprisingly, VEGF-CAC was a more powerful inducer of angiogenesis than even VEGF-$A_{165}$. VEGF-CAC gene transduction resulted in blood vascular leakage, endothelial proliferation, circumferential enlargement of arteries and veins, as well as formation of new blood vessel networks that were largely perfused. In addition, VEGF-CAC induced enlargement of the cutaneous lymphatic vessels, as reported previously with VEGF-$A_{165}$. These results may prove useful for the development of pro-angiogenic therapies in patients suffering from diseases associated with tissue ischemia.

659

**Expression, Regulation and Function of Low Density Lipoprotein Receptor-Related Protein and Urokinase Plasminogen Activator in GBM Cell Lines and the Genetic Modified Human Astrocytes**

Y. Zhao,[1] A. Xiao,[1] R. Abdel-Fattah,[1] S. A. Taylor,[1] R. O. Pieper,[2] I. M. Hussaini[1]; [1]Pathology, University of Virginia, Charlottesville, VA, [2]Neurological Surgery, University of California-San Francisco, San Francisco, CA

Low density lipoprotein receptor-related protein (LRP) is a multifunctional endocytotic receptor that is involved in regulating proteinase activity, which is necessary for cellular invasive processes. One of the well-characterized extracellular proteases is urokinase plasminogen activator (uPA), which plays an important role in the extracellular proteolytic degradation in cancer progression. In this study, we investigated (1) the expression of LRP in pilocytic astrocytoma and glioblastoma multiforme samples (GBM) from patients; (2) the expression of LRP and uPA at mRNA level and protein level in GBM cell lines and in the genetically modified human astrocytes, which resemble human grade II and III astrocytomas and grade IV GBM; (3) the regulation of LRP/uPA expression in NHA clones; (4) the correlation between the expression of LRP/uPA and cell invasion of these cells. Our results reveal that LRP was highly expressed in the pilocytic astrocytomas, but dramatically decreased in GBM; coincidentally, both mRNA and protein of LRP were highly expressed in normal human astrocyte (NHA), E6/E7 and Ras clones, while decreased greatly in EGFR clone and three GBM cell lines, U251, U1242 and U373. The level of uPA in NHA and E6/E7 clone was minimal, but increased in Ras and EGFR clones and in all of the four GBM cell lines. These results were consistent with the immunocytochemical localization of LRP/uPA in these cell lines/clones. Furthermore, the cell invasiveness of Ras and EGFR clones and all four GBM cell lines was significantly increased when compared with NHA. The invasion results correlate well with LRP/uPA expression. Our studies suggest strongly that LRP/uPA may be involved in the tumor cell local invasion, an important characteristic of brain tumor progression.

**Nerve Growth Factor Promotes Malignant Breast Epithelial Cell Migration Through a TrkA-dependent Mechanism**

S. Gehler, R. Schmocker, P. J. Keely; Pharmacology, University of Wisconsin, Madison, WI

Breast tumor metastasis is a multi-step process that requires cell migration through interstitial tissue. Neurotrophins are known to regulate survival, differentiation, and outgrowth of neuronal cells, but their effects on non-neuronal cells are not fully appreciated. It has been recently shown that NGF, not normally produced by normal breast epithelial cells, is synthesized and released by malignant breast epithelial cells in vivo (Dolle et al.,

2003). Although neurotrophins have been implicated in regulating the migration of Schwann cells, it is unclear whether neurotrophins have any effect on breast epithelial cell migration. We propose that NGF enhances the migration of transformed breast epithelial (T47D) cells through TrkA activation via an autocrine mechanism. First, NGF enhances collagen-mediated migration in a dose-dependent manner. For instance, 100ng/ml NGF induces a 2.5-fold increase in cell migration. This effect is specific for NGF, as brain-derived neurotrophic factor (BDNF) and NT-3 had no effect on migration. Second, we have demonstrated that NGF and the NGF receptors, TrkA and p75, are expressed on T47D cells using immunofluorescence and Western blot analysis. Third, treatment with a TrkA neutralizing antibody blocked the NGF-mediated increase in cell migration. In addition, the TrkA antibody inhibits migration of non-stimulated cells, which suggests autocrine effects of NGF on migration. These data suggest the novel idea that NGF enhances migration of T47D cells through a TrkA-mediated mechanism. Furthermore, NGF may mediate its effects through autocrine stimulation of T47D cells.

**IL-8 is a Potential Biomarker for Chemotherapy of Cervical Cancer**

L. F. Gulyaeva,[1] E. I. Schwartz,[2] V. O. Pustylnyak,[3] M. Bruinmsa,[4] S. E. Krasilnikov[5]; [1]Molecular Carcinogenesis, Institute of Molecular Biology and Biophysics, Novosibirsk, Russian Federation, [2]Department of Pathology, Georgetown University Medical School, Washington, DC, [3]Institute of Molecular Biology and Biophysics, Novosibirsk, Russian Federation, [4]NICHD, NIH, Bethesda, MD, [5]Gynecological Department, Regional Clinical Oncological Hospital, Novosibirsk, Russian Federation

Cervical carcinoma is the second leading cause of cancer deaths in women. In order to increase the efficiency of chemotherapy treatment, it is important to find a potential biomarker, which can be used as a prognosis indicator. Two of the possible candidates are the well-known angiogenic factor interleukin-8 (IL-8) and tumor suppressor gene B-cell leukemia/lymphoma 2 (Bcl-2), a suppressor of apoptosis. The level of gene expression of IL-8 and Bcl-2 in tumor tissues obtained after surgical operation of females with cervical carcinoma was studied. In order to study the possibility to improve survival and decrease toxicity, patients were subdivided into two groups: 19 patients (Group I) received a course of cisplatin, a form of chemotherapy, before surgery and 15 patients (Group-II) were operated on without chemotherapy and were treated with cisplatin after surgery. IL-8 and Bcl-2 expressions were determined by multiplex RT-PCR. Also, PCR-DNA techniques were used to detect the high-risk types of the human papillomavirus (HPV) 16/18. Nearly all of cervical cancer malignancies are the consequence of infection by HPV. Surprisingly, there were no significant differences in Bcl-2 mRNA levels in malignant and adjacent nonmalignant tissues between studied groups. However, IL-8 mRNA level was significantly higher ($p=0.021$) in cervical carcinoma than in adjacent non-transformed cervix tissues of both group patients. Moreover, in tumor tissues of cisplatin-treated patients the level of IL-8 gene expression decreased two fold compared to the untreated tumor. The present data suggests that IL-8 can be used as a potential biomarker in chemotherapy of cervical cancer. In order to further investigate this possibility we will check the correlation between IL-8 and Bcl-2 expressions and the presence of HPV16/18 in tumor tissues of cisplatin-treated and non-treated patients

**The Influence of TGF-α on ERE-(Luciferase)-Mediated Gene Expression in the MELN Breast Cancer Cell Line in the Presence of Estrogenic Stimulation**

S. D. Bowers, M. McGee, S. T. Willard; Animal and Dairy Sciences, Mississippi State University, Mississippi State, MS

Estrogen sensitive breast cancer cell lines, including stable photonic or fluorescent cellular models, have been used previously to evaluate the estrogenic activity of various compounds. However, few studies have addressed the interactions of various estrogenic agents (e.g., estradiol (E2), HPTE, etc.) in combination with endogenous factors (e.g., growth factors) that may augment treatment responses in these model cell lines. Transforming growth factor-α (TGF-α) has been shown to have synergistic and inhibitory effects on estrogen response element (ERE)-mediated gene expression in the presence of estradiol and various xenoestrogens depending on the duration of treatment. The objectives of this study were to determine whether the duration of TGF-α treatment would influence the effects of estrogenic stimulation on gene transcription in the ERE-luciferase MELN breast cancer cell line. Cultured, stably transfected MELN breast cancer cells were treated for up to 48 hr with varying concentrations of E2 (1 nM to 1 pM) in the presence or absence of TGF-α (10 ng/ml) or media alone (control). At 1 nM E2, the addition of TGF-α elicited a long term (48 hr) synergistic effect on ERE-mediated gene expression ($P<0.05$), however no short term synergistic effects were noted. Moreover at 10 pM E2, the addition of TGF-α elicited a long term (48 hr) combinatorial effect on ERE-mediated gene expression ($P<0.05$). At 100 pM E2, the addition of TGF-α elicited a short term (6 hr) combinatorial effect on ERE-mediated gene expression ($P<0.05$). These data demonstrate the influence of duration of TGF-α treatment on eliciting synergistic and combinatorial effects on estrogen stimulated ERE-mediated gene expression in the MELN breast cancer cell line. **Inhibition of ROS Generation and Cell Migration in Rat Metastatic Prostate Cancer Cells by A3 Adenosine Receptor Agonist**

S. Jajoo, V. Ramkumar; Pharmacology, Southern Illinois University,School of Medicine, Springfield, IL

The adenosine $A_3$ receptor ($A_3AR$) is a heterotrimeric G protein-coupled receptor expressed in variety of tumor cells including prostate cancer cells. Initial evidence suggests that activation of $A_3AR$ suppresses the growth of prostate cancer and melanoma cells in a mouse model. However, the role of $A_3AR$ in cancer cell metastasis is less well characterized. In the present study we test whether $A_3AR$ activation attenuates prostate cancer cell migration and what are the possible mechanism(s) involved in this process. The metastatic rat prostate adenocarcinoma (AT6.1) cells, used in this study, express high spontaneous reactive oxygen species (ROS) generation. Treatment of AT6.1 cells with an $A_3AR$ agonist,IB-MECA, suppressed ROS generation, as determined by the fluorescent probe, 2', 7'-dichlorodihydrofluorescein and confocal microscopy. ROS production was also reduced by compounds AEBSF and DPI, implicating NADPH oxidase as the source of ROS. $A_3AR$ activation also reduced the expression of NADPH oxidase subunits, Rac-1 and gp-91. In addition, IB-MECA reduced the high basal expression of NF-κB in these cells, an important facilitator of ROS-mediated gene expression in cancer cells. ROS plays an important role in the proliferation and metastasis of cancer cells. Hence, we looked for the AT6.1 cell migration using *in vitro* invasion chamber assay in the presence of IB-MECA. 24h treatment of cells with IB-MECA significantly inhibited the cell migration. We conclude that the $A_3AR$ tonically suppresses AT6.1 cells migration *in vitro* and could inhibit prostate cancer metastasis *in vivo*. One likely mechanism underlying inhibition of cell migration is a direct reduction of ROS generation via the NADPH

oxidase pathway and inhibition of gene expression via NF-κB. We propose that the $A_3$AR could serve as novel drug target for suppressing prostate cancer growth and metastasis.

**SIKVAV a Laminin-1-Derived Peptide, Binds Alpha3 Integrin and Regulates Protease Activity of a Human Salivary Gland Adenoid Cystic Carcinoma Cell Line through ERK Pathway**

V. Freitas,[1] V. Loureiro,[2] M. A. Juliano,[3] D. Pimenta,[4] A. C. Camargo,[4] M. Hoffman,[5] R. Jaeger[1]; [1]Cell and Developmental Biology, ICB-USP, São Paulo, Brazil, [2]UNIMES, Santos, Brazil, [3]UNIFESP, São Paulo, Brazil, [4]CAT, Butantan Institute, São Paulo, Brazil, [5]Matrix and Morphogenesis Unit, CDBRB, NICDR-NIH, Bethesda, MD

Adenoid cystic carcinoma is a frequently occurring malignant salivary gland neoplasm, with high level of recurrence and metastasis. We have demonstrated that laminin and its derived peptide SIKVAV regulates morphology and protease activity of a cell line (CAC2) derived from human adenoid cystic carcinoma. Here we studied the regulatory mechanisms underlying protease activity induced by SIKVAV in CAC2 cells. MMPs 2 and 9 were immunolocalized in adenoid cystic carcinoma cells *in vivo* and *in vitro*. CAC2 cells were cultured on SIKVAV, to analyze the role of this peptide in regulating protease activity. Zymography of the conditioned medium showed that SIKVAV enhanced secretion of MMPs 2 and 9. We analyzed a putative receptor for SIKVAV in CAC2 cells. Function-blocking antibodies to integrins alpha3beta1 and alpha6beta1 decreased both the adhesion of CAC2 cells to SIKVAV and protease secretion. A similar result was observed when cells were treated with EDTA. RNA interference (RNAi) was also used to silence alpha3 integrin expression. CAC2 cells with decreased alpha3 integrin expression were cultured on SIKVAV, and showed both decreased adhesion and protease activity. Furthermore, we isolated cell surface ligands using SIKVAV affinity chromatography, which were identified as alpha3 integrin by immunoblot. This result was confirmed by solid phase binding assays. We also defined a cell signaling pathway for the effect of integrins in CAC2 cells. A MAPK kinase inhibitor (UO126) decreased the effect of SIKVAV in the secretion of MMP-2 in CAC-2 cells, suggesting that SIKVAV signal is transduced by integrins and the ERK pathway. We propose that SIKVAV regulates protease activity of a human salivary gland adenoid cystic carcinoma cell line through integrin dependant signaling via the ERK pathway

665

**Fra-1-dependent Endocytosis in Mesothelioma Cells Modulates Migration**

M. E. Ramos-Nino, S. Blumen, T. Sabo-Attwood, J. Gell, N. Heintz, B. T. Mossman; Pathology, University of Vermont, Burlington, VT

Gene and protein profiling of mesothelioma cell lines reveal that Fra-1-dependent upregulated expression of endocytosis related genes (caveolin-1, clathrin, and rab27a) are causally related to the rate of migration in these cells. Fra-1, a member of the AP-1 family of heterodimeric transcription factors, is known to be overexpressed in many mesothelioma cells and tumors and has been reported by us to be important in mesothelial cell tumorigenesis, particularly in cell migration. Using microarray, confocal microscopy and standard protein techniques, our studies reveal that several endocytosis-related genes depend on Fra-1 expression and that this relationship accounts in part for the importance of Fra-1 expression in migration of mesothelioma cells. Supported by KO1 CA104159-01 (MERN)

**Role of Prohibitin and Glutathione-S-Transferase Pi in Taxol Resistance In Vitro**

S. K. Chatterjee, C. Waghorne, S. Lagasse, G. Najarro, B. R. Zetter; Vascular Biology Program, Childrens Hospital, Harvard Medical School, Boston, MA

Taxol, one of the most successful anti-cancer drugs, is used for the treatment of several metastatic cancers including breast, ovarian and non-small cell lung. Despite Taxol's efficacy, its applicability has been hampered by the development of Taxol resistance, which is observed both in vitro and in patients. P-glycoprotein has been a major contributor in conferring cellular Taxol resistance. Despite the success of P-glycoprotein inhibitors in reversing Taxol resistance *in vitro*, the same inhibitors have failed to reduce Taxol resistance in the clinic. In this study we used a proteomics approach find novel proteins associated with Taxol resistance. Two cell lines and their Taxol resistant variants were used in our study; a lung carcinoma cell line (A549) and its Taxol-resistant subline (A549 TR) and a uterine sarcoma cell line (MES-SA) and its Taxol resistant subline (MES-SA DX5). We found a set of proteins overexpressed in both the drug-resistant sublines compared to their sensitive parental cells. Prohibitin, was found to be a novel protein associated with Taxol resistance. In agreement with this we found that overexpressing prohibitin in the drug sensitive parental cell lines confers Taxol resistance to these cells. In addition, silencing prohibitin expression using siRNA in the Taxol-resistant sublines sensitizes these cells towards Taxol. Differential subcellular localization of prohibitin in the drug-resistant cells compared to the parents correlates with Taxol resistance though importance of prohibitin localization in mediating the resistant phenotype is unknown. Finally, we have shown that silencing both GST-π and prohibitin in concert reverses Taxol resistance significantly. This novel combination therapeutic strategy has implications for the treatment of drug-resistant tumors in the future.

**CA125 Tumor Antigen Regulates the Metastatic Potential of the OVCAR-3 Human Ovarian Cancer Cell Line**

C. Rancourt,[1] M. Pinard,[1] M. Boivin,[1] M. Migneault,[1] C. Batiste,[2] C. Theriault,[1] B. Paquette[2]; [1]Microbiologie, Universite de Sherbrooke, Sherbrooke, PQ, Canada, [2]Medecine nucleaire et radiobiologie, Universite de Sherbrooke, Sherbrooke, PQ, Canada

CA125 marker is overexpressed in most epithelial ovarian cancers and used to monitor disease progression. It is a highly glycosylated transmembrane mucin encoded by the *MUC16* gene. Mucins can influence cells metastatic potential. Identification of CA125 function in cells has been hampered by its challenging biochemical nature and large size cDNA. We generated an inhibitor that downregulates CA125 cell surface expression. It consists of an endoplasmic reticulum retained anti-CA125 single-chain antibody (scFv) that acts by sequestering CA125. Stable clones expressing the inhibitor or a control scFv were derived from OVCAR-3 human ovarian cancer cells. FACS analysis validated CA125 cell surface knockdown. To determine whether CA125 influences the OVCAR-3 cells metastatic potential, CA125 knockdown and control clones were compared for their homotypic cell-cell interaction, motility, migration and invasion capabilities. Cell aggregation assays showed that CA125 knockdown impairs cell-cell interaction. Scratch assays demonstrated that CA125 knockdown clones fill more rapidly wounded monolayers.

Migration assays in Boyden chambers confirmed an up to 200-fold increased cell motility. Matrigel-coated Boyden chamber assays showed an augmented invasiness of CA125 knockdown clones. Gene expression profiles of CA125 knockdown clones suggested increased expression of CD44 (10-fold) and proMMP-2 (5 to 10-fold). FACS analysis on non-permeabilized cells confirmed increased CD44 expression. Augmented proMMP-2 expression was validated by zymography which also showed an increased MMP-2 activity. Real-time PCR analysis revealed no change in MT1-MMP expression. Reverse zymography demonstrated a greater TIMP-2 expression supporting the augmented MMP-2 activity observed with zymography. The metastatic process involves the loss of homotypic cell-cell interaction and increases in motility, migration and invasiveness of cells. Our results demonstrate that CA125 cell surface knockdown generates such phenotypes and suggest that CA125 is a negative regulator of the metastatic potential of OVCAR-3 cells.

668

**Auto-Antibody Reactivity to Tumor Markers from both Native Serum Samples and In-Vitro Cell Culture**

M. C. Groll,[1] G. Goodrich,[2] J. D. Hoopes[1]; [1]Quansys Biosciences, Logan, UT, [2]Bioprocessing Inc., Scarborough, ME

Characterization of the relationship of auto-antibodies and antigen is needed to better understand their role in disease. It is hypothesized that auto-antibodies respond differently to antigen from native serum as opposed to cell culture derived antigen. In this study, 2 samples, one derived from sera and the other cell culture, of Alpha Fetoprotein (AFP), Carbohydrate Antigen (CA) 15-3, CA 19-9, CA 125 and Carcinoembryonic Antigen (CEA) donated by Bioprocessing Inc (Scarborough, MA) were screened using 48 random serum samples. 20 nano liter spots of each type of tumor marker, 10 in total, were deposited on the bottom of the well of a 96-well plate. The spots were incubated for 4 hours at 37ºC and then blocked with Quansys Blocker. The serum samples were then diluted in the supplied sample buffer at 1:100 dilution and incubated for 30 minutes at 20ºC on an orbital shaker. After washing each well with the Wash Solution, Quansys Detection was diluted to 1:1000 and added to the plate. This was incubated for 30 mins at 20ºC followed by another wash with the Wash Solution. Quansys Substrate was added and the plate was then imaged using the Fluorchem 8900 (Alpha Innotech Inc.) for 2 minutes. For each of the markers, a residual plot was graphed and analyzed. The $R^2$ of the following systems were AFP (0.64), CA 19-9 (0.94), CA 15-3 (0.18), CA 125 (0.29) and CEA (0.96). The CA 19-9 and CEA showed an acceptable correlation between the natural sera and antigen derived from cell culture. The AFP showed moderate correlation with the poorest correlation being CA 125 and CA 15-3. These poor correlations could potentially be caused by impure antigen samples as well as modified antigen via post-translational modifications.

**Multiplexed microELISA Used for Monitoring Renal Cell Carcinoma**

S. Call,[1] A. Ben-Jacob[2]; [1]Quansys Biosciences, Logan, UT, [2]Cache Valley Cancer Treatment Clinic, Logan, UT

Renal cell carcinoma accounts for approximately 2-3% of all adult malignancies. It does not respond well to radiation or chemotherapy; therefore surgery remains the most effective treatment. The objective of this study is to monitor renal cell carcinoma pre and post surgery to detect recurrence or advancement of the disease using multiplexed microELISAs. Through a collaborative project with Dr. Ali Ben-Jacob of the Cache Valley Cancer Treatment Clinic, a sample was taken one-week pre surgery to measure multiple tumor markers and cytokine levels using the Quansys Cancer Array and the Quansys Q-Plex™ Human Cytokine Array. The tumor markers that were measured include AFP, CEA, PSA, IL-6, hCGb, CA125, Prolactin (PRL), and CA19-9. The cytokines that were measured include IL-1α, IL-1β, IL-2, IL-4, IL-5, IL-6, IL-8, IL-10, IL-13, IFNγ, TNFα, and TNFβ. A follow-up sample was taken one-month post surgery to observe differences in the protein level expressions. The pre surgery sample yielded a CA19-9 level of 20 U/ml, and IL-6 of 90 pg/ml. The post surgery sample yielded a CA19-9 level of 20 U/ml and IL-6 of <2 pg/ml. Cancerous levels of CA19-9 are expected to be >37 U/ml. The CA19-9 level detected is expected in normal sera. Research has shown that IL-6 could be a potential marker for renal cell carcinoma. Normal levels of IL-6 are expected to range between 5-8 pg/ml. Responses of IL-6 between pre and post surgery samples indicate a definite decrease in IL-6 following the surgical removal of the tumor and kidney. This suggests IL-6 as being a potential marker for renal cell carcinoma. The multiplexed microELISAs prove to be effective tools for monitoring renal cell carcinoma.

670

**Induction of Apoptosis in Tumor Cell Lines by Polyphenolic Compounds Isolated from *Vaccinium macrocarpon***

L. Griffin,[1] S. Rego,[1] E. Correiro,[2] C. Neto,[3] P. Hart[1]; [1]Biology, UMass-Dartmouth, N. Dartmouth, MA, [2]Medical Laboratory Science, UMass-Dartmouth, N. Dartmouth, MA, [3]Chemistry and Biochemistry, UMass-Dartmouth, N. Dartmouth, MA

Polyphenolic compounds, including those present in cranberry fruit, have a cytotoxic effect on a variety of tumor cell lines, and we have investigated the possibility that these cytotoxic effects are mediated through one or more apoptotic pathways. Polyphenolic-rich extracts from cranberry fruit were isolated and fractionated by HPLC. Breast tumor cells, MCF-7, and normal breast epithelial cells, MCF10A, were cultured under standard conditions either in the presence of a total polyphenolic extract (TPE) or fractions of the TPE enriched for distinct classes of polyphenolics. The cellular effect(s) of the compounds were assayed using a fluorescent TUNEL assay and a BrdU incorporation assay. The TPE or ursolic acid induced apoptosis in the MCF-7 cells at a frequency of 92.3% and 98.1%, respectively. These effects appear to be tumor-cell-specific as apoptosis was not induced with either the TPE or ursolic acid in MCF10A cells to a significant extent. Additionally, similar effects were observed in colon tumor cell lines, HT-29 and HCT-116. These results suggest that polyphenolic compounds may hold some chemopreventative or chemotherapeutic promise.

671

**The Mechanism of CRMP-1 in Modulating TNFα-mediated NF-κB Activation**

C. Wang, H. Shih; The Institute of Biomedical Sciences, Academia Sinica, Taipei, Taiwan Republic of China

Metastasis is the major cause of cancer-induced death. Recent study showed that CRMP-1 (collapsing mediator protein-1) expression suppresses tumor metastasis and is associated with survival rate of patients suffering lung cancer. Furthermore, a defect in the TNFα/NF-κB-mediated IL-8 induction was observed in the CRMP-1 expressing cells. The molecular mechanism of CRMP-1 in downregulating the TNFα/NF-κB signaling and associated cellular events remains unknown. In the present study, we demonstrate that CRMP-1 attenuates TNFα/NF-κB signaling through direct

interaction of NF-κB subunit p65/RelA protein. We first demonstrated that TNFα-induced expression of IL8, cIAP1 and cIAP2 was reduced in CRMP-1 overexpressing cells. Epistatic analysis of TNFα-mediated signaling molecules revealed that CRMP-1 functions as a downstream molecule of p65. Accordingly, TNFα-induced IκBα phosphorylation/ degradation and p65 nuclear translocation were not affected by CRMP-1 expression. *In vitro* and *in vivo* binding studies further indicated that CRMP-1 binds to p65 carboxy terminus and blocks its transactivation and DNA binding activities. Furthermore, depletion of CRMP-1 expression by RNA interference approach increased TNFα-induced NF-κB reporter activation and target gene expression. Lastly, increased or decreased CRMP-1 expression resulted in enhanced or reduced TNFα-mediated cytotoxicity, respectively. In summary, our data provide the mechanistic insight of CRMP-1 in modulating TNFα-mediated NF-κB activation.

672

**L1-CAM, a Novel Target of β-Catenin-TCF Signaling, Transforms Cells and is Expressed at the Invasive Front of Human Colon Cancers**

N. Gavert,[1] M. Conacci-Sorrell,[1] P. Altevogt,[2] T. Brabletz,[3] A. Ben-Ze'ev[1]; [1]Molecular Biology of the Cell, Weizmann Institute of Science, Rehovot, Israel, [2]Tumor Immunology Programme, German Cancer Research Center, Heidelberg, Germany, [3]Department of Pathology, University of Erlangen-Nurnberg, Erlangen, Germany

L1-CAM, a Novel Target of Beta-Catenin-TCF Signaling, Transforms Cells and is Expressed at the Invasive Front of Human Colon Cancers. Beta-Catenin, a protein linking cell adhesion molecules to the cytoskeleton, is also a prominent transcriptional activator during embryogenesis that is aberrantly activated in many human cancers. Stabilizing mutations in beta-catenin, or mutations in its degradation pathway, are among the early and primary changes seen in human colon cancer. Using cell lines and human tissue, we identified the neuronal cell adhesion molecule L1-CAM as a target gene of beta-catenin-TCF signaling in colorectal cancer cells. L1-CAM expression confers increased cell motility, invasion, growth in low serum and transformation. In mice, L1-CAM over-expressing human colon cancer cells were tumorigenic, and when injected into the spleen, exhibited extensive liver metastases. In human colorectal cancer, L1-CAM was exclusively localized at the invasive front of such human tumors, together with ADAM10, in cells also displaying nuclear beta-catenin. L1-CAM expression in human colon cancer cells could therefore be useful for detection, and as a target for colon cancer therapy.

673

**D2 (but not D1 and D3) Dopaminergic Receptor Agonists Inhibit Cholangiocarcinoma Growth by Activation of $Ca^{2+}$/$IP_3$/PKC-gamma**

H. Francis,[1] S. Glaser,[2] S. DeMorrow,[1] J. Venter,[3] R. Reichenbach,[4] R. Summers,[3] B. Green,[3] A. Coots,[1] Y. Ueno,[5] G. Alpini[6]; [1]Scott & White Hospital, Temple, TX, [2]Scott & White Hospital/The Texas A&M University HSC/COM, Temple, TX, [3]The Texas A&M University HSC/COM, Temple, TX, [4]Central Texas Veterans HSC, Temple, TX, [5]Division of Gastroenterology, Tohoku University School of Medicine, Sendai, Japan, [6]Scott & White Hospital/The Texas A&M University HSC/COM/Central Texas Veterans Hospital, Temple, TX

Cholangiocarcinoma is a devastating biliary cancer with limited treatment strategies. Three dopaminergic receptor subtypes (D1, D2 and D3) exist. Activation of D2 dopaminergic receptors by the D2 agonist, quinelorane, inhibits the growth of Mz-ChA-1 cells by activation of $Ca^{2+}$/PKC. **Aims**: (i) To evaluate the effects of D1, D2 and D3 receptors on Mz-ChA-1 growth; and (ii) to further evaluate the mechanisms by which D2 receptors inhibit Mz-ChA-1 growth. **Methods:** We utilized three cholangiocarcinoma cell lines: Mz-ChA-1 cells (from gallbladder); HuH-28 (from intrahepatic ducts) and TFK-1 (from extrahepatic ducts). Receptor expression was evaluated. Time and dose effects were evaluated in cells stimulated with 0.2% BSA (basal) or the D1 agonist, SFK-82958, quinelorane, or the D3 agonist, 7-Hydroxy-DPAT (10, 25, 50, 100 μM for 24 and 48 hours). Mz-ChA-1 cells were stimulated for 48 hours with BSA or quinelorane (25 μM) in the absence/presence of: BAPTA/AM ($Ca^{2+}$ chelator, 5 μM); Gö6976 (PKCα inhibitor, 1 μM); HBDDE (PKCγ inhibitor, 50 μM) or CGP53353 (PKCβI & II inhibitor, 1 μM; obtained from Novartis Pharma AG, Basel, Switzerland). MTS assay was performed. $IP_3$ levels were measured in Mz-ChA-1 cells stimulated with quinelorane. Phosphorylation of PKC α, βI, βII and γ was evaluated by immunoblots from Mz-ChA-1 cells treated with quinelorane for 90 minutes. **Results:** Mz-ChA-1, TFK-1 and HUH 28 cells express all three dopaminergic receptors. Quinelorane decreased growth in Mz-ChA-1 cells at 10, 25, 50, 100 μM for 24 and up to 48 hours. D1 and D3 agonists did not effect growth. Quinelorane inhibition of Mz-ChA-1 growth was blocked only by BAPTA/AM and HBDDE. Quinelorane increased $IP_3$ levels and the phosphorylation of PKCγ. **Conclusion:** Dopaminergic innervation through interaction with D2 agonists may lead to therapeutic strategies for cholangiocarcinoma treatments.

674

**Ephrin-B/EphB Receptor Signaling Controls Morphology and Migration of Murine Melanoma Cells**

N. Yang,[1] E. B. Pasquale,[2] L. B. Owen,[3] I. M. Ethell[1]; [1]Division of Biomedical Sciences, Biochemistry and Molecular Biology Program, University of California, Riverside, CA, [2]The Burnham Institute, San Diego, CA, [3]BioLegend, San Diego, CA

Malignant melanomas are difficult to treat as compared with other types of skin cancer and the incidence of malignant melanomas is increasing faster than that of any other malignancy in the United States. The Eph receptors form the largest family of the receptor tyrosine kinases, which is divided into two classes, A and B, according to their ligand affinity and sequence similarity. Several studies have demonstrated expression of B class Ephs and ephrins in a variety of tumors and suggested a functional relationship between their expression and tumor progression. Here we show an association between expression of EphB receptors, especially EphB4, and the migratory ability of murine melanomas. Highly malignant melanoma cells express the higher levels of EphB4 receptors, which are also phosphorylated on tyrosine suggesting high kinase activity. The melanoma cells expressing highest levels of EphB4 and its ligand, ephrin-B2, migrate faster and show more polarized cell morphology compared to less malignant melanoma cells. Furthermore, we demonstrate that inhibition of ephrin-B/EphB signaling by overexpression of dominant-negative EphB4ΔC, or by treatment with soluble EphB2-Fc, both result in slower migration of highly malignant melanoma cells. Inhibition of EphB4 receptor activity has also pronounced effects on melanoma cell morphology and actin organization. Moreover, the overexpression of active EphB4 in slow migrating melanoma cells significantly enhances cell migration. These data suggest that ephrin-B/EphB receptor signaling contributes to the high migratory ability of melanoma cells most likely by influencing cell substrate adhesion and actin cytoskeleton organization.

### Specific, Dynamic and Non-Invasive Labeling of Pancreatic Beta-Cells in Reporter Mice Expressing a Proinsulin-EGFP Fusion Peptide

A. Ben-Yehudah,[1] B. Reinhart,[2] C. Navara,[1] J. Kotzuk,[2] S. F. Witchel,[3] G. Schatten,[1] R. Chaillet[2]; [1]Pittsburgh Development Center, University of Pittsburgh, Pittsburgh, PA, [2]Department of Molecular Genetics and Biochemistry, University of Pittsburgh School of Medicine, Pittsburgh, PA, [3]Department of Pediatrics, University of Pittsburgh School of Medicine, Pittsburgh, PA

We have developed a non-invasive tool for the detection of directed differentiation of human ES cells into β cells for the treatment of diabetes. Here, we present an efficient, innovative approach for imaging pancreatic β cells. The main physiologic function of β cells is glucose-stimulated insulin secretion. This function is facilitated through the synthesis and storage of insulin in secretory vesicles of β cells, which then release their contents when β cells are exposed to hyperglycemic conditions. To visualize β cells *in vivo* in the mouse, we used targeted mutagenesis techniques to construct a modified *insulin II* (*InsII*) gene allele, $InsII^{EGFP}$ that expresses a proinsulin-EGFP fusion peptide. The EGFP portion of this fusion is entirely within the C-peptide portion of the proinsulin peptide. Prior studies with this construct demonstrated: a) targeting of the fluorescence to vesicles; b) glucose-stimulated secretion of insulin and C-peptide$^{EGFP}$ into the medium; and c) secretatogue-stimulated (KCl and sulfonylurea) secretion of insulin and C-peptide$^{EGFP}$ into the medium. This fusion protein is processed in β cells to insulin and EGFP-tagged C peptide, which are stored together in cytoplasmic secretory vesicles. The large amount of vesicular EGFP-tagged C peptide is evident as a characteristic robust and specific fluorescence pattern in the β cells of $InsII^{EGFP}$ mice. This innovative method of visualizing β cells will be a useful tool in the study of both β cell physiology and the development of the endocrine cells of the pancreas.

### A Comparison of Optical Clearing Agents to Enhance Photonic Detection of *Salmonella* through Pig Skin

K. E. Moulton,[1] E. Williams,[1] F. Lovell,[1] P. Ryan,[1] D. Lay,[2] D. Jansen,[3] S. Willard[1]; [1]Department of Animal and Dairy Science, Mississippi State University, Mississippi State, MS, [2]Livestock Behavior Research Unit, USDA-ARS, West Lafayette, IN, [3]Department of Biomedical Engineering, Vanderbilt University, Nashville, TN

The objective of this investigation was to evaluate glycerol (GLY), glucose (GLU), sucrose (SUC), and corn syrup (CS) as agents to optically clear pig skin and increase photonic transference and detection of photon emitting *Salmonella typhimurium* (*S. typh*-lux; transformed with plasmid pAKnlux1), in a laboratory model for *Salmonella* detection in swine. Shoulder pig skin obtained after harvest was processed to remove hair and subcutaneous fat, and the skin measured for thickness. A 96-well plate containing *S. typh*-lux was imaged for 5 min using a photon counting camera (Berthold/Nightowl) as a control reference. Skin (2 mm thick) was placed over the plate containing *S. typh*-lux and imaged 5 min. The skin was then treated for 4 h with varying ratios of GLY, GLU, SUC, and CS in a dose-dependent manner and the plate imaged again 5 min. The percent of photonic emissions (treated or untreated skin relative to no skin controls) from 3 replicates within 8 skin pieces per treatment were used for statistical analysis. Treatment for 4 h with 100% CS increased ($P<0.05$) photonic emissions (21.6 ± 2.0 %) compared to untreated skin, 50% GLY and 50% SUC (0.6 ± 0.2, 17.7 ± 0.8 and 13.6 ± 1.8 % respectively). However, 75% SUC and 50% SUC increased ($P<0.05$) photonic emissions (17.7 ± 1.3 and 17.7 ± 1.3% respectively) compared to 75% GLU, 50% GLY and untreated skin (15.3 ± 1.1, 15.4 ± 0.8 and 1.1 ± 0.1 % respectively). These data indicate GLY, GLU, SUC, and CS may be used as effective optical clearing agents on pig skin when treated for 4 h to allow for an increased detection of emitted photons from *S. typh*-lux through skin. [USDA-NRI grant# 2003-35201-13841; USDA-ARS Biophotonic Initiative# 58-6402-3-0120].

### Imaging Subcellular Structure with Hard X-ray

P. Tseng, Y. Hwu; Institute of Physics, Academia Sinica, Taiwan, Taipei, Taiwan Republic of China

We present a experimental evidence that hard X-ray can be used to image the sub-cellular structure at 60 nm resolution. In this study, the live, staining free, plant and animal cells could be imaged by coherent unmonochromatic synchrotron source. X-ray microscopy using un-monochromatic synchrotron source achieve the resolution about 1 um. At this scale, tissue specimens could be imaged at cell level. To localize the distribution of specific protein, we use immunocytochemistry to label the intermediate filaments, vimentin, inside the cytoplasm of HeLa cells. The DAB with nickel enhancement were used as chromogen to increase the absorption contrast. The cell nuclei could be identified because they were free from vimentin staining. When high definition phase zone plate and monochromatic synchrotron source were applied to X-ray microscopy, the images were substantially improved. It permits 60 nm resolution and promises to reach a 25nm resolution. The X-ray emitted from synchrotron source was monochromatized by double crystal monochromator, the photon energy was fixed at 8 keV to optimize the focusing efficiency of the zone plate. The texture of vimentin network at the peri-nuclear area and the vimentin bundles at the cell lamellapodia can be clearly identified. The When compared with visible light and laser confocal microscope, the x-ray microscope provides a superior resolution to both conventional optical microscopes.

### Simultaneous Imaging and Analysis of Cellular Dynamics in Three Dimensions in Fluorescence Microscopy

P. Prabhat,[1,2] Y. Chao,[1] S. Ram,[1,3] E. S. Ward,[1] R. J. Ober[1,2]; [1]Center for Immunology, University of Texas Southwestern Medical Center, Dallas, TX, [2]Department of Electrical Engineering, University of Texas at Dallas, Richardson, TX, [3]Joint Biomedical Engineering Graduate Program, University of Texas at Arlington / University of Texas Southwestern Medical Center, Arlington / Dallas, TX

Fluorescence microscopy of live cells is an invaluable tool to investigate cellular trafficking pathways. The existing microscope design is very well suited to image fast moving vesicles, tubules and organelles in one focal plane. However, the imaging of such cellular components that move between different focal planes is problematic. Since this would require a focusing device that changes the focal plane of the microscope, which is typically slow. Moreover, in this approach only one focal plane can be imaged at a time. Hence when the cell is imaged at one focal plane, important events could be missed at other focal planes. To overcome these shortcomings, we recently reported a novel modification to the classical microscope design that enables the simultaneous imaging of two distinct focal planes within the sample (1). In our current study, we have extended

this setup to acquire images simultaneously from up to four distinct focal planes. This setup has enabled the study of trafficking behavior that spans a larger depth within the cell than was possible with the earlier configuration. Human endothelial cells were imaged using this setup to study the dynamics of fluorescently labeled FcRn. Trafficking events that would be difficult to study without simultaneous imaging of multiple focal planes will be presented. The visualization and analysis of data acquired from different focal planes poses new challenges. We present software tools that were developed for this purpose. 1. Prashant Prabhat, Sripad Ram, E. Sally Ward and Raimund J. Ober, Simultaneous Imaging of Different Focal Planes in Fluorescence Microscopy for the Study of Cellular Dynamics in Three Dimensions, IEEE Transaction on Nanobioscience, **3**(4), 237-242, (2004) Supported by grants from the NIH (R01 AI39167, R01 AI50747 and R01 AI55556)

## Spatial and Temporal Characterization of the Metabolic Response of PC12 Cells to Stimulation: A Two-Photon NADH and Flavoprotein Fluorescence Study

C. H. Keith,[1] E. Porter,[1] A. T. Sornborger[2]; [1]Cellular Biology, University of Georgia, Athens, GA, [2]Math/Engineering, University of Georgia, Athens, GA

It has long been known that the fluorescence of NADH and flavoproteins can be used to estimate the metabolic load being put on cells, Functional imaging measurements of NADH/Flavoprotein fluorescence have focused on imaging relatively large areas of cortex. We are using two-photon fluorescence microscopy of NADH and flavoprotein to measure the metabolic response of the trigeminal ganglion of zebrafish larvae to facial stimulation with irritants (Sornborger et al, Soc. Neurosci. Abstract 2005) In order to rigorously analyze and model these responses of neurons to stimulation, we need to establish the relative contribution of the opening of various channels to their metaobolic response. Therefore, we are stimulating differentiated and non-differentiated PC12 cells with pulses of isotonic high $K^+$ modified PBS, both in the presence and absence of 1 mM $Ca^{++}_o$, as a way of isolating the metabolic loads engendered by ion fluxes consequent to the opening of a variety of different channels. We find that the metabolic response of naïve and differentiated cells to depolarization differs in both magnitude and form, and that the presence or absence of $Ca^{++}_o$ can change their response. We also find that the changes in fluorescence on stimulation is limited to micron-sized punctae within the cytoplasm, consistent with its being largely, if not exclusively, mitochondrial in origin. Therefore, we feel that 2-photon fluorescence microscopy will represent a powerful, non-invasive technique to measure the response of cells to stimuli, both *in vitro* and *in vivo*. ## $CC^3$: A Stable, Sterile Analog of Poly-D-Lysine that is Optimal for the Culture of Fastidious Cells in Normal and Reduced Serum Media

W. Lu,[1] D. Schroen,[2] H. McIntosh,[2] T. Cummins[1]; [1]Research and Development, Nalge Nunc International, Rochester, NY, [2]Marketing, Nalge Nunc International, Rochester, NY

Poly-D-lysine (PDL) coating of cell culture surfaces improves attachment and growth of certain fastidious cells. However, the PDL surface cannot be considered formally sterile, because current irradiation methods alter the coating function in cell culture. Most PDL surfaces claim a short term shelf life and often require controlled storage conditions. To improve the PDL surface, a non-biological analog of PDL ($CC^3$), a synthetic organic polymer with high amine group density and positive charge in neutral media, has been investigated for its function and stability in cell culture. PC12, HEK293, CHO and BHK cells have been selected, to evaluate the effect of the $CC^3$ surface on cell culture using normal and reduced serum media. Data shows equivalent cell attachment and growth on PDL vs. $CC^3$-coated surfaces when HEK, CHO, BHK and PC12 cells are incubated in normal serum media. HEK, CHO and BHK cells gradually adapt to reduced serum media over several weeks. The attachment, growth and morphology of three cell lines on the $CC^3$ surface in low serum media are similar to those on PDL surfaces. An accelerated aging test shows that the $CC^3$ surface is stable for cell culture for up to 5 years. Importantly, the $CC^3$ surface can be sterilized with gamma-irradiation to SAL $10^{-6}$ levels. Reproducibility of the $CC^3$ surface was demonstrated using 90 plates, including 6 different formats and coated in 3 separate procedures. In all plates, excellent cell attachment and growth was demonstrated. We conclude that $CC^3$ surface is a stable, sterile, non-biological analog of PDL surface, which mimics the function of PDL surface for cell culture in normal and reduced serum media, yet exhibits an extended shelf life, and withstands sterilization treatment.

## Tandem Screening of Toxic Compounds on GFP-Labeled Bacteria and Cancer Cells in 96-Well Culture Plates

J. Montoya,[1] A. Varela-Ramirez,[1] M. Shanmugasundram,[2] L. E. Martinez,[2] T. P. Primm,[1] R. J. Aguilera[1]; [1]Biology, University of Texas at El Paso, El Paso, TX, [2]Chemistry, University of Texas at El Paso, El Paso, TX

A 96-well assay has been developed for the rapid screening of potential cytotoxic and bacteriocidal compounds. The assay is based on detection of GFP (Green Fluorescent Protein) in mammalian (HeLa) cells and gram negative (*Echerichia coli*) and gram positive bacteria (*Mycobacterium avium*). Addition of a toxic compound to the GFP marked cells resulted in the loss of the GFP fluorescence which was readily detected by fluorometry. Using this assay, we screened thirty nine distinct naphthoquinone derivatives and found that several of these compounds were toxic to all cell types. In these assays, plumbagin was clearly the most toxic of the test compounds on both the mammalian cells and the two bacterial strains. In addition, two structurally similar compounds, naphthazarin and menadione, were also found to exhibit highly toxic to all cell types. Apart from plumbagin, lapachol was found to be the most toxic to *M. avium*. Two general types of toxic compounds were detected, those that exhibited toxicity to two or all three of the cell types and those that were primarily toxic to the HeLa cells. As the toxicity of these two sets of compounds targets different cell types, it is likely that these compounds will have different modes of action. The tandem analysis of different cell types allowed for the detection of differences in toxicity that would not have been detected if the compounds had been tested on a single cell type. Our results demonstrate that the parallel screening of both eukaryotic and and prokaryotic cells is not only feasible and reproducible but also cost effective.

## Low Density Lipoprotein/High Density Lipoprotein on Au(111) Substrate: Atomic Force Microscopy Visualization

A. Segura Salvador,[1,2] N. Batina[1]; [1]Departamento de Quimica, Universidad Autónoma Metropolitana, Mexico City, Mexico, [2]Facultad de Ciencias

Químicas., Universidad Autónoma Benito Juárez de Oaxaca, Oaxaca, Mexico
The low density lipoprotein (LDL) is the vehicle for cholesterol transport inside the human body. It's a positively charged spherical particle with 25 nm of diameter. Inside arteries, can deposit into solid plaque, causing a disease known as atherosclerosis characterized by hardening and loss of elasticity of the walls of the blood arteries. The high density lipoprotein (HDL) is a negatively charged particle, with diameter of 12 nm. It participates in lipid transport, however not in the arterial accumulation. The atomic force microscope (AFM) is an instrument of nanotechnology and surface science, capable to research molecular aggregates with low conductivity, revealing topography of surface at molecular scale. It can operate in variety of media, including aqueous, which has a special importance for visualization of biological surfaces. As majority of samples for AFM analysis, LDL and HDL were fixed at the atomically flat Au(111) substrate. Samples were prepared from diluted physiological solutions: $8x10^{-14}$ M LDL and $8x10^{-13}$ M HDL at 37 °C and visualized by AFM, in air. Individual molecules and very interesting aggregates of LDL and HDL were seen. LDL aggregates form some kind butterfly like features, which show great affinity towards the gold substrate because of there's hydrophilic character. Some of lipoproteins were found to be aggregated as tetrameters with a diameter of 174 nm. HDL molecules were found to be adsorbed at borders of the substrate, preferring rather substrate steps than flat terraces. The adsorbed adlayers of HDL were 38 nm high. The observed differences in the adsorbed layer structure and preferential adsorption sites were discussed from point of the different type of interactions of LDL and HDL with gold substrate. This could help to understand the arterial plaque formation helping to design nanometric scale bio-devices.

**Quantitative Analysis of Striated Muscle Structure by Second Harmonic Imaging**

S. V. Plotnikov,[1] A. C. Millard,[2] A. B. Isaacson,[1] V. Juneja,[1] P. J. Campagnola,[2] W. A. Mohler[1]; [1]Department of Genetics and Developmental Biology, University of Connecticut Health Center, Farmington, CT, [2]Department of Cell Biology, Center for Cell Analysis and Modeling, University of Connecticut Health Center, Farmington, CT
Several endogenous protein structures (e.g. collagen fibrils, myosin filaments within a sarcomere, tubulin arrays) produce strong second harmonic signals with high contrast against the background. This discrete photonic emission can be imaged at high three-dimensional spatial resolution on a laser scanning microscope yielding a detailed digital profile of the histological arrangement of native tissue samples (Campagnola et al., 2002). In this study we demonstrate two quantitative analyses of SHG relevant to muscle structure. First, we demonstrate that, as in case of collagen, myosin α-helical coiled-coil domains are the elemental harmonophores in the actomyosin lattice. Based on the assumption that SHG occurs within cylindrically symmetric arrangements of identical harmonophores, from polarization analysis we calculate the pitch angles for myosin α-helix. The pitch angle values correspond to X-ray diffraction data (Beck and Brodsky, 1998). Similarly, the angle derived for collagen agrees well with ultrastrucutral findings for the glycine-proline helix. Furthermore, polarization anisotropy of myosin and collagen SHG are significantly different allowing us to distinguish these two proteins spectroscopically. Second, we find that quantitative analysis of the periodicity, the intensity, and the regularity of the sarcomeric repeat patterns of striated muscle probed by SHG imaging may be useful in differentiating normal and diseased muscle tissue. Using hindlimb-suspended mice as a model of muscle atrophy, we observe both significant reduction in fiber size (cross section area), and areas with myosin filament disorganization and partial or complete loss of myofibril integrity. These results suggest the use of SHG imaging as a powerful tool for the structural analysis of muscle tissue and the monitoring of specific muscular disorders.

**Cell-Cycle Dependence of the FTIR Micro-spectroscopic Spectra of Single Proliferating Eukaryotic Cells**

S. Boydston-White,[1] T. Chernenko,[1] A. Regina,[1] M. Diem[1,2]; [1]Chemistry and Biochemistry, Hunter College of the City University of New York, New York, NY, [2]PhD Program in Chemistry, Graduate School and University Center of the City University of New York, New York, NY
We are studying the cell-cycle dependence of the FTIR and Raman micro-spectra of single proliferating eukaryotic cells to determine the spectral patterns of individual cells as a function of their state of maturation, differentiation and development. FTIR micro-spectroscopy of normal *vs.* neoplastic cells and tissues have shown differences in the spectral absorption intensities and band-shapes, particularly in the low frequency (900-1200 $cm^{-1}$) spectral region. To understand these differences, we must associate the observed spectral changes with the drastic biochemical and morphological changes occurring as a consequence of cell proliferation. We avoided any chemical perturbations leading to cell-cycle arrest in efforts to synchronize cells, but instead employed a "mitotic shake-off" to select cells in mitosis and followed them through a time course. To confirm each cell's biochemical age, we used immunocytochemical staining to detect specific temporal cellular events --- including the appearance (and subsequent disappearance) of cyclins E and B1 and the incorporation of 5-bromodeoxyuridine into nascent DNA during synthesis. Once the biochemical age was confirmed, the spectra collected could be unambiguously-assigned to particular cell-cycle phases and the spectral differences analyzed. These differences at the various time points of the cell cycle manifested themselves in pronounced changes, especially in the second derivative analysis. Shifts in the amide I peak position, indicative of different protein structures were found in the spectra of the nucleus at different time points; the amide II peak showed a distinct low frequency shoulder in the second derivative that is barely evident in the absorption spectra; and the peak at 1238 $cm^{-1}$ is observed strongly in the average second derivative spectra of all populations, but is particularly strong in the standard deviation S-phase spectrum.

685

**An Optically driven, Bacterial Screw of Archimedes**

J. R. Robbins,[1] D. Tierney,[2] H. Schmitzer[2]; [1]Biology, St. Mary's College of California, Moraga, CA, [2]Physics, Xavier University, Cincinnati, OH
The ability to rotate micromechanical elements with light is an important development in micromechanics. The three techniques to generate an opto-mechanical rotation are the spin angular momentum transfer to birefringent, micron-scale objects, the orbital angular momentum transfer by helically wound light beams and the linear momentum transfer to asymmetrically shaped structures. This final item poses the largest problem, since the production of such micro-gears is not simple. Evolution, however, provides a great diversity of engineered forms in nature. Various bacteria or cells could be useful as cheap, mass-producible elements in manmade micro-scale systems. In this work we show that the helical bacterium Rhodospirillum rubrum rotates very quickly when held in an optical tweezer. This rotation is fast enough to create a strong vortex current. It can therefore act as a micro-mixer in solution or cell culture, as well as a micro-pump or a micro-rotor to turn tiny gears in biophysical applications.

**Correlating Morphological and Electrophysiological Properties of Interneurons, Using Automated Image Analysis**

A. Woodruff,[1] P. Sah,[1] C. Sun,[2] L. Bischof,[2] R. Lagerstrom,[2] I. Sintorn,[2] M. Buckley,[2] P. Vallotton[2]; [1]Queensland Brain Institute, Brisbane, Australia, [2]CMIS, CSIRO, North Ryde, Australia

Electrophysiological properties of neurons allow classifying them into different subtypes based on their distinct firing properties. Interneurons in the basolateral amygdala can be distinguished into four types as shown by their different levels of adaptation in response to a prolonged (400 ms) depolarising current injection. Here, we investigate whether these observed subtypes are associated with distinct morphologies using automated image analysis of two-photon confocal microscopy data. After filling neurons with Alexa 594, we segment the measured neurites from 3D confocal stacks using a new, sensitive linear feature detector, followed by skeletonization and pruning of artefactual branches. Statistical tests based on measures of the topology of these trees revealed small differences between the different subtypes indicating that expression of different of ionic conductances, rather than morphology only, was responsible for the differences observed. This is an important finding in the endeavor towards building a mathematical model of neurons.

687

**Multiphoton Excitation-evoked Chromophore-assisted Laser Inactivation Using Green Fluorescent Protein**

T. Tanabe,[1] M. Oyamada,[1] K. Fujita,[2] P. Dai,[1] H. Tanaka,[1] T. Takamatsu[1]; [1]Pathology and Cell Regulation, Kyoto Prefectural University of Medicine, Kyoto, Japan, [2]Department of Applied Physics, Graduate School of Engineering, Osaka University, Suita, Japan

Noninvasive and straightforward methods to inactivate selected proteins in the living cell with high spatiotemporal resolution are eagerly awaited for elucidation of protein function in the post-genome-mapping era. Chromophore-assisted laser inactivation (CALI) facilitates inactivation of proteins by photochemically generated reactive oxygen species (ROS), but CALI using single-photon excitation thus far has presented several drawbacks, including complex procedure, low efficiencies of inactivation with a certain chromophore, and photodamage effects. We here show that by application of multiphoton excitation to CALI using near-infrared femtosecond laser, enhanced green fluorescent protein (EGFP) can work as an effective chromophore for inactivation of a protein's function within a subfemtolitter volume without nonspecific photodamage in the living cell (MP-CALI). We found that ≈80% reductions of gap junctional currents between HeLa cell pairs expressing connexin43 (Cx43) tagged with EGFP but not between HeLa cell pairs expressing Cx43 tagged with monomeric red fluorescent protein (mRFP) were elicited by brief laser irradiation (< 500 ms) at 850-nm wavelength of the gap junctional plaque at 2.7 MW/cm$^2$ laser irradiance. Next, MP-CALI was applied to aurora B, a chromosome passenger protein, tagged with EGFP, expressed in MDCK cells. The MP-CALI parameters were as follows: laser irradiance, 1.5 MW/cm$^2$; pixel dwell time, 9.36 μs; total scan area, 10 X 13.3 μm; total scan time, 8.1 s. At metaphase, MP-CALI of aurora B-EGFP inhibited the segregation of chromosomes (14/16), which were consistent results that aurora B is required for mitosis. EGFP-mediated MP-CALI is a straightforward, non-invasive method useful for inactivation of proteins in living cells with high spatiotemporal resolution.

**Protein Kinase C α (PKCα) is Involved in Nuclear Factor κ B (NFκB) Signalling**

P. Morton,[1] S. Ameer-Beg,[2] M. Keppler,[1] T. Ng[1]; [1]Randall Division, Kings College London, London, United Kingdom, [2]The Advanced Technology Group, The Gray Cancer Institute, Middlesex, United Kingdom

The transcription factor NFκB is an important regulator of carcinogenesis. The Inhibitor of κB kinase (IKK) complex is essential for NFκB activation and requires phosphorylation by an unknown kinase for its activity. The aim of this study is to determine whether PKC is involved in the NFκB signalling pathway through an interaction with the IKK complex. Forster Resonance energy Transfer (FRET) analysis was performed to determine the potential interaction between IKKβ-GFP and PKCα-mRFP1 after stimulus with tumour necrosis factor α (TNFα) and Trichostatin A (TSA); two activators of NFκB signalling. Data presented shows that a time dependent interaction occurs between IKKβ-GFP and PKCα-mRFP1 after TNF or TSA treatment. Parallel assays were performed to determine the effect of inhibiting PKCα with a conventional PKC inhibitor on TNFα and TSA induced NFκB dependent luciferase activity. Results presented show that TSA induced NFκB activity was dramatically reduced by the c-PKC inhibitor, however TNFα induced activity is not affected by inhibition of c-PKC. This indicates that TSA and TNFα activate NFκB via different upstream kinases. In conclusion PKCα interacts with IKKβ after TNFα or TSA treatment, however the kinase activity of PKCα is only required for TSA induced NFκB activity. It is possible that in the TNFα induced pathway PKCα is acting as a scaffold protein for a second kinase. This study will provide insight into the aberration of NFκB signalling seen in cancer cells and may help in the design of chemotherapeutic drugs for the many cancers where NFκB is either constitutively active or overexpressed.

**New Reagents and Probes for Optical Switching of Biomolecules**

T. Sakata,[1] Y. Yan,[2] G. Marriott[1]; [1]Physiology, University of Wisconsin-Madison, Madison, WI, [2]Mechanical Engineering, University of Hawai`i, Honolulu, HI

We introduced a family of thiol reactive spirobenzopyrans (BIPS) and a spironaphthoxazine (NISO) as a new approach for optical switching of biomolecular interactions [Sakata et al, (2005) PNAS, 102(13), 4759-4764; Sakata et al, (2005) J. Org. Chem., 70(6), 2009-2013]. BIPS and NISO undergo efficient, rapid and reversible, optically-driven transitions between a colorless and weakly polarized spiro (SP) state and a colored, highly polarized and weakly fluorescent merocyanine (MC) state without the release of photoproducts. In this presentation, we describe the design, synthesis and characterization of new functionalized BIPS and NISO probes and reagents that can serve: (a), as photochromic acceptor probes for FRET (PC-FRET) on proteins and within membranes; (b), as part of a new approach to perturb structure and activity of protein complexes and other polymers via optical switching between the SP and MC states. The new optical switch probes were synthesized by coupling appropriately functionalized indoline derivatives with salycilaldehydes (BIPS) or nitrosonaphthol (NISO) derivatives. Spectroscopic and biochemical analyses showed that these probes can be directed to specific sites where they undergo rapid and reversible optical transitions between the SP and MC states. Suitable examples will demonstrate the potential of these probes and optical switching to study complex biological systems.

690

**Development of a Multi-well, Total Internal Reflection Microscopy System for Kinetic Screening of Plasma Membrane Translocation Events in Thousands of Single Cells in Parallel**

S. Devasenathipathy, K. Li, T. Meyer, M. N. Teruel; Molecular Pharmacology, Stanford University, Stanford, CA

We have developed a multi-well, multi-channel, wide-field, total internal reflection (TIRF) microscopy system (Teruel and Meyer, Science, 295: 1910-1912, 2002) with accurate temperature/CO2 control and rapid fluid exchange, capable of measuring up to three plasma membrane signaling parameters such as PIP3 levels and secretion events in parallel in thousands of individual cells over time. Being able to acquire large numbers of single-cell responses allows us for the first time to ask questions about the timing between plasma membrane protein activation steps and the signaling processes that control them without washing out the critical delay and amplitude information. The multi-well format was custom-fabricated by spin-coating an amorphous fluoropolymer (Cytop, refractive index: 1.34) onto a glass slide and etching a 12-well pattern into the teflon-like film using oxygen plasma etching and conventional photolithography. Each well is approximately 1.5mm in diameter in order to hold 200-300 cells. The automated fluid exchange/delivery system can exchange stimuli to cells in the entire 12-well imaging area on the order of 1 second. The cells in each of the wells are transfected with a different combination of DNA or siRNA, making it possible to carry out 12 separate translocation timecourse experiments in parallel. Using this format, we have begun screening a library of siRNAs to identify proteins that control the plasma membrane translocation of signaling reporters such as C2-domains, glucose transporter 4 (GLUT4) and the PH-domain from AKT (Tengholm and Meyer, Current Biology, 12: 1871-1876, 2002).

691

**Correlated Light and Electron Microscopic Imaging of Multiple Endogenous Proteins Using Quantum Dots**

B. N. G. Giepmans, T. J. Deerinck, B. L. Smarr, Y. Z. Jones, M. H. Ellisman; Department of Neurosciences, The National Center of Microscopy and Imaging Research (NCMIR) at UCSD, La Jolla, CA

The importance of locating proteins in their context within cells has been heightened recently by the accomplishments in structural and systems biology. While light microscopy is extensively employed for mapping protein localization, many studies require the additional resolution of the electron microscope. Here we report the application of small nanocrystals (Quantum dots) to specifically and efficiently label multiple distinct endogenous proteins for light and electron microscopy analysis. Quantum dots are both fluorescent and electron dense facilitating their use for correlated microscopic analysis. Furthermore, Quantum dots can be discriminated optically by their emission wavelength and physically by size, making them invaluable for multi-labeling analysis. We developed pre-embedding labeling criteria using Quantum dots that are straightforward and allow optimization at the light level, before continuing with electron microscopy preparation and analysis. Experiments varying fixation strength, detergent time and type are most often required to balance accessibility, preservation and retention of antigenicity. Each tissue, cell, antigen an target location presents a little different challenge. Benefits of using Quantum dots include optimization of staining procedures with examination at the LM level, straightforward multi-protein labeling at the LM and the EM, and increased penetration as compared to traditional immunogold. We show examples of double and triple immunolabeling using light, electron and correlated microscopy in cells and tissue. We conclude that Quantum dots may aid in higher-throughput analysis of determination of precise protein localization at the LM and EM levels. Supported by NIH-RR04050, NIH-NS27177, NIH-1P20-GM72033

**Automated Motion Detection and Quantitation of Cell Components: Application to Dynamic Populations of Microtubules in Living Cells**

A. Altinok,[1] A. J. Peck,[2] S. C. Feinstein,[3] L. Wilson,[2] K. Rose,[4] B. S. Manjunath[1]; [1]Electrical and Computer Engineering, University of California at Santa Barbara, Santa Barbara, CA, [2]Molecular, Cellular and Developmental Biology, University of California at Santa Barbara, Santa Barbara, CA, [3]Neuroscience Research Institute, University of California at Santa Barbara, Santa Barbara, CA, [4]Center for Bio-Imaging, University of California at Santa Barbara, Santa Barbara, CA

Live cell imaging technologies have advanced enormously over the past decade. However, in most cases, analysis remains a painstaking, tedious and largely manual task, limiting the quantity and quality of resulting data. Here, we describe (i) the development of novel software that automatically detects and quantifies changes in the location of objects of interest in living cells and (ii) the application of this software to the analysis of populations of GFP-labeled microtubules (MTs). More specifically, we have developed software that uses thresholding, difference analysis and lateral motion removal to automatically track and quantify the growing and shortening behavior of populations of MTs in living cells. Our new software improves dramatically upon the currently available means to analyze MT behavior. Through automated detection of all visible MTs in a fluorescence image stack in a visible cellular region (>100 MTs), each stack produces considerably more usable data in considerably less time while removing possible unintentional operator bias. Additionally, our technique preserves intact, ordered event histories of MT populations, possibly elucidating novel MT population behaviors which cannot be described by single event frequencies and average rates calculated from parsed data sets. Finally, global analysis of MT populations could reveal regional, behavioral specificities and MT population inter-relations, possibly integral to specialized processes such as cell division and neuronal outgrowth. Taken together, this highly exportable technique improves our ability to address existing questions while making it possible to use statistics to ask novel questions regarding the behavior of MT populations (and other objects of interest) that have not been approachable previously. (Supported by NSF Information Technology Research Grant 0331697.)

**LAMP, a New Fluorescence Imaging Assay Employing a New Class of Photoactivatible Fluorophores, Sheds Light on the Regulation of Gap Junctional Communication**

K. A. Dakin, W. Li; Cell Biology, University of Texas Southwestern Medical Center, Dallas, TX

Gap junction channels allow adjacent cells to communicate via the transfer of small molecules and ions and play important roles in cell homeostasis and synchronization. The regulation of cell coupling through connexin channels has been under intensive investigations. We have recently developed a new fluorescence imaging technique, LAMP (Localized Activation of Molecular Probes), for studying dynamic junctional communication in fully intact cells. Using the LAMP assay, we discovered that calcium influx through store operated channels strongly inhibits gap junction channels composed of Cx43. To understand the mechanism of inhibition, we investigated the involvement of cytosolic pH ($pH_i$), local

$Ca^{2+}$ rises near sites of $Ca^{2+}$ influx, and other cytosolic factors in the gating of Cx43 channels. Since we observed a modest $pH_i$ drop during calcium influx, we examined the possibility of synergism between $[Ca^{2+}]_i$ rise and $pH_i$ abatement. Reducing $pH_i$ down to 6.5 using a weak acid had little effect on cell coupling by itself, and clamping $pH_i$ to physiological levels during calcium influx did not prevent the inhibition of junctional communication. In contrast, buffering $[Ca^{2+}]_i$ with BAPTA, but not EGTA, largely suppressed cell uncoupling by $Ca^{2+}$ influx. These results suggest that localized $Ca^{2+}$ elevation, rather than cytosolic acidification, mediates the inhibition of cell coupling during $Ca^{2+}$ influx. To extend the LAMP technique to assay cell-cell communication in three dimension, we resorted to the technique of two photon uncaging and imaging. This new class of caged fluorophores possesses very high two photon excitation cross sections at wavelengths above 700 nm, and thus are ideal fluorescent probes for imaging molecular movements in physiological preparations.

694

**A Versatile Low-cost Multi-mode Laser Microsurgery Workstation**

V. Magidson, A. Khodjakov; Molecular Medicine, Wadsworth Center, Albany, NY

Intracellular manipulations on the level of the individual intracellular organelles are becoming increasingly popular among cell biologists. There is a growing demand for workstations capable of combinational laser ablation/photobleaching/photoactivation techniques. We describe a relatively inexpensive but versatile instrument that can be assembled in an average biological laboratory and is virtually maintenance-free. The system is capable of diffraction-limited laser ablation/photobleaching and low-light 4-D imaging of live cells. It utilizes two lasers: a 532-nm pulsed Nd:YAG (Diva II, Thales; 8-ns pulses) used for ablation, and a 488-nm CW laser for photobleaching. Both beams are steered to the microscope objective lens through a dedicated epi-port available on the Nikon TE-2000 inverted microscope. This design allows us to avoid moving parts (such as dichroic mirrors or filter cubes) in the beam path which greatly improves reproducibility of resolution-limited targeting for laser ablation. Further, our design permits continuous observation of the target during laser ablation. Distortion-free attenuation of the beam is achieved via a two-stage conditioning system. First, double internal reflection on a flat parallel glass window is used to decrease the pulse power approximately 500-fold. Then, a rotatable polarizer/half-wave plate is used for finer adjustments. This design also allows us to match polarization of the laser beam to the orientation of the Wollaston prism, preventing beam splitting often observed in DIC-based systems. Variable-zoom focusable beam expander (<1/8 wavelength beam distortion - Special Optics) is used to match beam diameter to the objective lens aperture. Capabilities of our system have been proven by cutting individual microtubules and microtubule bundles in a variety of cells ranging from yeast to mammals. Further, we illustrate high precision of laser targeting by ablating just one of the two centrioles positioned <500 nm from each other.

695

**Electron Tomography of Cells and Tissues - Studying the 3D Structure of Molecular Machines in their Native Cellular Environment at Molecular Resolution**

H. Palsdottir,[1] J. Remis,[1] M. Zemla,[1] K. McDonald,[2] M. Auer[1]; [1]Life Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA, [2]University of California, Berkeley, CA

It is widely accepted that proteins do not act in isolation, but are organized into molecular machines. Using electron microscope (EM) tomography imaging we can visualize the 3D structure of such molecular machines in their native cellular environment. Our studies include the mechanoelectrical transduction and adaptation machinery of hair cells, responsible for the senses of hearing and balance. In particular we will present tomographic analysis of the extracellular links in hair cell stereocilia. We will show that a model of the candidate protein cadherin 23 is consistent with densities of the basal links, but is not consistent with tip link 3D reconstructions. Instead we propose fibronectin to be part of the tip link. We also study cell-cell and cell-matrix adhesion complexes of kidney glomerular podocytes, breast cancer acini and bacterial biofilms. To ensure faithful sample preparation we employ high-pressure freezing/freeze-substitution, followed by resin-embedding and sectioning. These structural studies are complemented by the quest for novel EM labeling methods that rely on genetically encoded tags recognized either by the membrane-permeable fluorophore ReAsH (followed by photoconversion) or by Ni-NTA-Nanogold (followed by gold enhancement). In addition to tomographic 3D data, we will present preliminary results on specific tag-based EM labeling of organelle-targeted proteins. Using transgenic zebrafish it is our goal to specifically label tagged proteins and combine high-precision 3D localization of tagged proteins with 3D ultrastructure of high-pressure frozen, freeze-substituted zebrafish larvae to obtain insight into the composition and building principles of cellular machines.

**High Content Kinetic Imaging Screens Identify Roles of GTPase Activating Proteins in Cancer Cell Biology**

T. R. Jackson,[1] S. Fitch,[1] C. A. Robson,[2] P. Andras,[3] R. K. Martin,[1] N. A. Daniels[1]; [1]Bioimaging, University of Newcastle upon Tyne, Newcastle upon Tyne, United Kingdom, [2]Northern Institute for Cancer Research, University of Newcastle upon Tyne, Newcastle upon Tyne, United Kingdom, [3]School of Computing Science, University of Newcastle upon Tyne, Newcastle upon Tyne, United Kingdom

Recent developments in automated fluorescence microscopy have allowed the emergence of high content screening {1} as a powerful tool for the investigation of integrative systems biology. Imaging allows quantitative investigation of multiple biological parameters in living cells allowing investigators to monitor the results of parallel pharmacological and molecular genetic manipulation of individual signalling pathway components. We have utilised a kinetic imaging fluorescence microscopy system to investigate the requirement for Arf-GTPase Activating protein function in regulation of the cell cycle, endocytosis and the cycle. These studies support the function of β centaurins {2} as regulators of these processes in human cancer cells. The successful execution of high content screening is dependent on access to digital imaging microscopy in a controlled cell culture environment, appropriate assay design and critically on software for automated data interrogation, quantification and visualization. We have developed and/or modified a number of novel java tools including those for measurement of cell movement and cell tracking which we have implemented for use with data stored in accordance with emerging standards of the Open Microscopy Environment {3}. {1} **Image-based screening: a technology in transition** Ramm P *Current Opinion in Biotechnology* 2005, **16** (1): 41-48. {2} **β centaurins in cancer** Martin RK, Jackson TR *Biochem Soc Trans* 2005, *in press* {3} **The Open Microscopy Environment (OME) Data Model and XML file: open tools for informatics and quantitative analysis in biological imaging** Goldberg IG, Allan C, Burel JM, Creager D, Falconi A, Hochheiser H, Johnston J, Mellen J, Sorger PK, Swedlow JR *Genome Biology* 2005, **6**(5):R47.

**Optimization and Use of the Biarsenical Binding Tetracysteine Motif for Fluorescence and Affinity**

B. R. Martin,[1] B. N. G. Giepmans,[2] S. R. Adams,[1] R. Y. Tsien[3]; [1]Pharmacology, University of California, San Diego, La Jolla, CA, [2]Neurosciences, University of California, San Diego, La Jolla, CA, [3]Pharmacology, Chemistry and Biochemistry, and the Howard Hughes Medical Institute, University of California, San Diego, La Jolla, CA

Membrane-permeant biarsenical dyes such as FlAsH and ReAsH fluoresce upon binding to genetically encoded tetracysteine motifs expressed in living cells, yet spontaneous non-specific background staining conceals weakly expressed or dilute proteins from detection. If the affinity of the tetracysteine peptide could be increased, then stringent dithiol washes should increase the contrast between specific and nonspecific staining. Residues surrounding the tetracysteine motif were randomized and fused to GFP, then retrovirally transduced into mammalian cells and iteratively sorted by fluorescence-activated cell sorting for high FRET from GFP to ReAsH despite increasing concentrations of dithiol competitors. Selected sequences demonstrate higher fluorescence quantum yields and drastically improved dithiol resistance, culminating in a >20-fold increase in contrast. Fusion of a tetracysteine tagged CFP (FlAsH or ReAsH) or GFP (ReAsH) to a cellular protein allows biarsenical fluorescence to be monitored by FRET from the donor fluorescent protein to the nearby, genetically fused biarsenical-tetracysteine acceptor. By excluding non-specific biarsenicals from being excited, FRET mediated detection increases ReAsH contrast almost 8-fold, making it only 2-fold less than GFP. Fusion of a tetracysteine barely increases the size of the fluorescent protein, but potentially provides the extended functionalities of the biarsenical-tetracysteine system, such as fluorescent pulse-chases, photoinactivation, and EM photoconversion. The best tetracysteine sequences, e.g. FLNCCPGCCMEP, maintain their enhanced properties as fusions to either termini of GFP or directly to β-actin, and should enable detection of a much broader spectrum of cellular proteins. Additionally, the sequence YRECCPGCCMWR fused to the N-terminus of GFP precipitates upon binding ReAsH. Fusions of this tetracysteine-GFP to the N-terminus of several cellular proteins show rapid ReAsH-triggered aggregation. This aggregation is reversible upon bleaching of the ReAsH fluorophore and may lead to a new method of protein inactivation in living cells.

**Wet Electron Microscopy Using Quantum Dots**

W. Timp,[1] N. Watson,[2] A. Sabban,[3] O. Zik,[3] P. Matsudaira[4]; [1]Electrical Engineering, MIT, Cambridge, MA, [2]Whitehead Institute for Biomedical Research, Cambridge, MA, [3]Quantomix Corporation, Nes-Ziona, Israel, [4]Biology, MIT, Cambridge, MA

Light microscopy is the current technique of choice for high-resolution biological imaging. However, light microscopy is limited in its ultimate resolution to $0.61\lambda/NA$ or around 100nm. Achieving this ultimate resolution is nontrivial, involving careful optimization of the microscope combined with computational deconvolution. Electron microscopy may be used to obtain higher resolution images, with a possible spatial resolution on the order of 10 nm with scanning electron microscopy (SEM). However, attaining contrast on biological samples with an electron microscope is not as straightforward as it is using optical methods. Enhancing biological sample contrast requires complicated preparation techniques, including critical point drying, coating, embedding, and sectioning. Expensive equipment and extensive training are required in order to prepare a sample for normal electron microscopy using these techniques. Instead, we have used wet electron microscopy, which is essentially electron microscopy in a sealable capsule. Specifically, we were looking for information the actin cytoskeleton of IC-21 cells. The microstructure of these actin filaments, specifically, information about how they are organized may give us more insight as to the mechanism of cell motility. In order to have sufficient contrast on these samples, we have tried a variety of stains, from uranyl acetate to colloidal gold particles. The most interesting result came from using quantum dots. Quantum dots are semiconductor particles which fluoresce at wavelengths defined by their size. Quantum dots are very useful as a stain because they are visible in light microscopy as well as in electron microscopy. This allows us to do correlative microscopy on the same sample, without any further preparation or modification. The resolution benefits granted by SEM can be used to explore further information already obtained from fluorescent microscopy.

**Site-specific 3D Imaging of Cells and Tissues With a Dual Beam Microscope**

J. A. W. Heymann,[1] M. Hayles,[2] I. Gestmann,[2] D. Shi,[1] B. Lich,[2] S. Subramaniam[1]; [1]National Cancer Institute, Bethesda, MD, [2]FEI Company, Eindhoven, The Netherlands

Current approaches to 3D imaging at subcellular resolution using confocal microscopy and electron tomography, while powerful, are limited to relatively thin and transparent specimens. Here we report the development of a new generation of dual beam electron microscopes that are capable of site-specific imaging of the interior of cellular and tissue specimens at spatial resolutions significantly better than those currently achieved with optical microscopy. The principle of imaging is based on using a focused ion beam to create a cut at a designated site in the specimen, followed by viewing the milled surface with a scanning electron beam. Iteration of these two steps several times thus results in the generation of a series of surface maps of the specimen at regularly spaced intervals. The three-dimensional maps obtained with this sequential “slice-and-view strategy” are at resolutions as high as ~ 10 nm in-plane and ~ 100 nm in the vertical direction. We demonstrate the potential of dual beam microscopy for biological imaging using critical-point dried yeast cells imaged at room temperature, as well as frozen yeast cells and tissue specimens imaged at -140 °C. Besides the opportunities for in situ 3D imaging of cells and tissues, we demonstrate that the dual beam microscope can be used to generate thin sections as well as cylindrically shaped specimens that can be subsequently examined in a transmission electron microscope.

**Application of SERS Nanoparticles to Intracellular pH Measurements**

T. A. Laurence,[1] C. Talley,[2] M. Colvin,[3] T. Huser[2]; [1]Physical Biosciences Institute, Lawrence Livermore National Laboratory, Livermore, CA, [2]Chemistry and Materials Science, Lawrence Livermore National Laboratory, Livermore, CA, [3]University of California, Merced, Merced, CA

We present an alternative approach to optical probes that will ultimately allow us to measure chemical concentrations in microenvironments within cells and tissues. This approach is based on monitoring the surface-enhanced Raman scattering (SERS) response of functionalized metal nanoparticles (50-100 nm in diameter). SERS allows for the sensitive detection of changes in the state of chemical groups attached to individual nanoparticles and small clusters. Here, we present the development of a nanoscale pH meter. The pH response of these nanoprobes is tested in a cell-free medium, measuring the pH of the solution immediately surrounding the nanoparticles. Heterogeneities in the SERS signal, which can

result from the formation of small nanoparticle clusters, are characterized using SERS correlation spectroscopy and single particle/cluster SERS spectroscopy. The response of the nanoscale pH meters is tested under a wide range of conditions to approach the complex environment encountered inside living cells and to optimize probe performance. This work was performed under the auspices of the U. S. Department of Energy by the University of California, Lawrence Livermore National Laboratory under Contract No. W-7405-Eng-48.

### Intracellular Calcium Measurements In Exocrine Cells Using Tirf Microscopy

J. Won, D. I. Yule; Pharmacology and Physiology, University of Rochester, Rochester, NY

In non-excitable cells agonist-stimulated $Ca^{2+}$ signals consist of both $Ca^{2+}$ release and $Ca^{2+}$ influx. We have investigated the contribution of these processes to near membrane $Ca^{2+}$ signals in pancreatic and parotid acinar cells using Total Internal Reflection Fluorescence (TIRF) microscopy. In extracellular $Ca^{2+}$ free conditions to isolate $Ca^{2+}$ release, physiological agonist stimulation resulted in $Ca^{2+}$ oscillations in both pancreas and parotid when measured with fluo-4 (kd=345nM). These signals did not differ significantly in profile or amplitude from those measured with wide-field microscopy. These data presumably reflect the fact that $Ca^{2+}$ release in these polarized epithelia, although triggered very close to the apical plasma membrane is occurring at some distance from the area subjected to TIRF microscopy. In contrast, when $Ca^{2+}$ influx was isolated either following agonist stimulation or after depletion of intracellular pools the $Ca^{2+}$ signals evoked were more rapid and robust than measured with wide-field microscopy and often appeared to result in saturation of fluo4, but not of the low affinity dye fluo-4 FF (kd=9700nM). Robust $Ca^{2+}$influx was initiated even at physiological concentrations of agonist which result in minimal store depletion. Interestingly, $Ca^{2+}$ influx in parotid acinar cells was 4 fold greater than that initiated in pancreatic acinar cells. These data indicate that TIRF microscopy is a sensitive measurement of $Ca^{2+}$ influx and potentially provides a useful technique to study the mechanisms which underlie these processes in polarized epithelia.

### YOMICS™ : Antibody Libraries for Functional Proteomics

M. Pagani, F. Marinoni, E. Pedrazzoli, A. Bresciani, D. Cattaneo, P. Sarmientos; Molecular Biology, PRIMM srl, Milan, Italy

In the last years, numerous studies have concentrated on the elucidation of the molecular mechanisms of human pathologies showing that most diseases are the consequence of an altered expression and/or the malfunction of one or more proteins involved in the regulation of cellular processes. A substantial acceleration in the elucidation of the molecular mechanisms underlying the diseases development and in our ability to diagnose and cure maladies is expected to take place in the next few years due to the application and implementation of high-throughput technologies that stem from the scientific revolution brought about by genome sequencing and analysis (genomics and bioinformatics), that includes transcriptome analysis (transcriptomics) and proteome analysis (proteomics). The availability of a "draft" of the entire human genome sequence and, most important, the accurate annotation of the sequences of several human chromosomes virtually allows the physical isolation of all human genes Here we describe our reverse-proteomics approach, called YOMICS, applied to the analysis of several uncharacterized human transmembrane and secretal proteins. This approach has the aim to develop high-value tools to allow a rapid definition of protein expression profiles in both normal and pathological human samples. PRIMM has developed a high-throughput cloning and expression technology. Genes are amplified, cloned into the PRIMM developed vectors and the derived recombinant plasmids are used to transform different *E. coli* strains. Once expressed, the proteins are purified by affinity chromatography and used for polyclonal antibody production. The availability of a sera library against a large panel of human proteins is the key feature of the YOMICS project. We are employing these antibodies and the purified proteins for protein-protein interaction studies, differential expression and localization analysis in normal or pathological conditions using *in vivo* (eg. FACS) and in vitro (eg. immunochemistry) analysis techniques.

### High-Throughput and High-Yield Protein Expression

T. W. Sproul, A. M. Burt, R. D. Guettler, L. T. Mazzola; Excellin Life Sciences, Menlo Park, CA

Expression cloning is an important tool in academic and industrial research, whether for transient expression of cDNA libraries or stable incorporation for production clones. Recently there has been a push toward high-throughput expression analysis; however, this approach lacks a consistent front-end process for high-throughput generation of transfected cells. Current methods for transfection can be extremely labor intensive and can't be used for all cell types. Furthermore, high levels of cDNA induction are often desirable to differentiate exogenous vs. endogenous expression - current transfection methods limit the amount of material that can be safely delivered into the cells. Here we demonstrate high levels of expression easily and reliably achieved for cytosolic, transmembrane and secreted proteins using a novel microelectronic transfection process. Transfection achieved 80-95% overall efficiency (90-95% cell viability), as indicated by dsRed, GFP, PAG-GFP fusion and CD4 protein production in a variety of cell lines. This technique is consistent with high-throughput and high-volume processing for both suspension and *in situ* adherent cell types - including primary and stem cells.

704

### Novel Nanoelectronic Chips for Gene Profiling and Proteomics

H. Chen, A. M. Cassell, J. Koehne, M. Meyyappan, J. Li; Ames Research Center, Moffett Field, CA

Microarray is an important tool for high throughput analysis of biomolecules. The use of microarrays for parallel screening of nucleic acid and protein profiles has become an industry standard for drug discovery and biomarker identification recently. But it requires relatively large sample volumes and elongated incubation time due to the large spot size. This also limits the sensitivity of detection. In addition, traditional microarray uses bulky instrument for the detection requires major efforts in sample amplification and labeling, which increase the cost and delay the time for getting the results. These drawbacks are the biggest impediment to move the nucleic acid and protein based detection to point-of-care and field applications. To overcome above limitations, Carbon Nanotube (CNT) based nanoarrays are developed by using nanotechnologies. In this nanoelectrode array platform, individually addressed ultra-microspot is about 10 μm x 10μm$^2$, consisting of tens or hundreds of nanoelectrode with

a diameter of 50 to 100 nm, which are inlaid in insulating materials such as $SiO_2$ with only the very end exposed. We have demonstrated them for ultrasensitive nucleic acid analysis by label-free electrochemical detection. These nanoarrays are also being developed for highly sensitive protein filing. CNT nanoelectrode arrays are also much easier in automation and date analysis. These nanoarrays will have significant applications in drug discovery, medical diagnosis, genetic testing, environmental monitoring, and food safety inspection with novel gene profiling and proteomics tools

**Two-Dimensional Organelle and Organellar Subtype Fractionation for Subcellular Proteomics Studies**

H. Tran, D. E. Kalman, J. A. Smith, W. Lan; Alfa Wassermann Proteomic Technologies, LLC, West Caldwell, NJ

The challenge of subcellular proteomics lies with the separation, fractionation and enrichment of organelles and organellar subtypes. Here we present a 2-dimensional centrifugation technique: our novel proteomic continuous-flow ultracentrifugation (pCFU$^{TM}$) combined with differential centrifugation to achieve the dynamic range of organelle fractionation. Initially, pCFU separates and enriches organelles at their buoyant density using a sucrose gradient. The continuous-flow nature of the technique allows accumulation of the organelles due to the unlimited amount of sample that can be loaded. Differential centrifugation of pCFU fractions further separates organelles by their sedimentation rates. In this study, HeLa cells were homogenized and nuclei were removed by low speed centrifugation. After 2-dimensional ultracentrifugation, Western blot analysis showed significant differences in organelle distributions between 2-dimensional fractionation and differential centrifugation alone. The differences in the mitochondria patterns between fractions from pCFU demonstrated the power of separation of organellar subtypes. Furthermore, compared to the starting material the fractions from pCFU showed enrichment and accumulation of organelles. Fractions from the 2-dimensional organelle fractionation process were subjected to SDS gel electrophoresis for separation of proteins. Slices from these gels were then analyzed by nano-LC-ESI-MS/MS for protein identification. With 65 fractions from pCFU, 4 fractions from differential centrifugation and 20 slices from SDS gel electrophoresis, a potential of 5200 samples can be analyzed by mass spectrometry which provides the ability to analyze the entire proteome.

706

**Mapping and Functional Characterization of Phosphorylation Sites in *Drosophila* Flightin**

D. J. Lemas,[1] M. Previs,[2] J. Vigoreaux[1]; [1]Biology, University of Vermont, Burlington, VT, [2]Cell and Molecular Biology, University of Vermont, Burlington, VT

Flightin is a novel 20-kD myofibrillar protein found in *Drosophila* indirect flight muscles (IFM), the principal muscles that power flight. Previous studies have shown that flightin is essential for normal thick assembly during muscle development and required for thick filament stability in active, adult contracting muscle. Evidence suggest that phosphorylation of flightin plays a dual role in dictating thick filament length during development and modulating the contractile properties of the muscle. Currently eleven flightin isoelectric variants, two non-phosphorylated variants (referred to as N1 and N2) and nine phosphorylated variants (P1 through P9), have been identified in vivo by two-dimensional gel electrophoresis (2DE) of IFM fibers. We are conducting matrix assisted laser desorption ionization time-of-flight (MALDI-TOF) mass spectrometry of 2DE gel spots to identify the phosphorylation sites in flightin and to determine if each 2DE spot constitute a single form or a mixture of different phosphorylated forms. Phosphorylation site mapping shows that most sites are found in clusters in the C-terminal two thirds of the protein. Phylogenetic analysis revealed that some of the sites are not conserved among *Drosophila* species suggesting that their role may be modulatory. To test the hypothesis that phosphorylation of flightin is a mechanism for modulating power output, we are measuring the relative levels of flightin isovariants in non-flying and flying *Drosophila melanogaster* by quantitative 2DE. Our results show dynamics changes in the relative abundance of non-phosphorylated and phosphorylated flightin isovariants as flies transition from rest to full flight. This study will provide new insight into the role of phosphorylation in dictating the contractile dynamics of muscle *in vivo*.

707

**Behavior of Protein Complexes in Native Two-Dimensional Gel Electrophoresis**

J. E. Smotrys, L. Chen, C. S. Giometti; Argonne National Laboratory, Argonne, IL

Protein complexes play a major role in the normal metabolism of all cell systems. Methods for the isolation of intact complexes continue to be a challenge, since the association constants between the components vary. Two-dimensional (2D) gel electrophoresis is a powerful tool for the separation of complex protein mixtures and provides the opportunity to identify the proteins when coupled with peptide mass analysis. Electrophoresis of proteins under nondenaturing conditions preserves their native conformations, allowing for detection of enzymatic activities and the identification of the components comprising protein complexes (Giometti *et al*. 2003 *Proteomics* 3:777). Two questions regarding native gel electrophoresis are addressed in this work. First, do known protein complexes remain associated during 2D native electrophoresis? We have demonstrated that trypsin and soybean trypsin inhibitor form a complex that survives the high voltage conditions experienced during 2D native electrophoresis. Secondly, what is the size limitation of gel separation-based methods? Native protein samples are likely to contain very high molecular weight complexes that may be excluded from entry into traditional polyacrylamide gels because of their size. Using proteins with a range of molecular weights, we have shown that a mixture of agarose and acrylamide can be successfully utilized for second-dimension electrophoresis that allows greater gel penetration of high molecular weight proteins than use of polyacrylamide alone. These results confirm the important role that 2D electrophoresis can play in future proteomic studies that emphasize protein functions and interactions.

708

**Developing an Add and See Array System Using FRET(Fluorescence Resonance Energy Transfer) to Detect Protein Interaction**

J. Lu, P. C. Byrne; Pathology, UCD, Dublin, Ireland

The problems associated with developing high-throughput screening of protein interactions on a protein chip include difficulties in determining whether (i) the proteins on the chip are denatured, (ii) the specificity of the reaction and (iii) the relative strength of protein interaction. The multiple steps required in most current systems hamper widespread use and commercialisation. Here, We provide preliminary results on the development of an add and see (A&C) array system using FRET (Fluorescence Resonance Energy Transfer) to detect protein interaction. A library of prokaryotic and eukaryotic plasmids expressing enhanced fluorescent protein tagged (EFP, i.e. EYFP/ECFP) target or probe fusion protein sequences is prepared. The plasmids with EFP-probe and EFP-target fusion proteins also have different antibiotic resistance genes. Both plasmids

were heat-shock co-transfected into E coli. Protein expression was induced by addition of IPTG. The E. coli expressing target proteins were loaded onto multi-well plates or slides (array/chip, Add). The cells in the array were fixed and scanned for FRET reaction to indicate the existence of protein interaction (See). Array cells that were positive for FRET are further examined in a eukaryotic system. The method is easy to standardize for automation. With EFPs used as quality and quantity internal controls, it is possible to perform intra- and inter-chip checks and measure the relative binding strength by calculating the FRET efficiency. We are looking for collaborators and sponsors for proteomic scale work with this system.

709

**Blotless Nano Western - A New Approach for High Performance Protein Assays of Stem Cells and Other Precious Biological Materials**

E. T. Gentalen, X. Bi, J. Ferrante, J. Gossett, C. Kirby, B. Loder, M. MacLaren, T. Mills, R. O'Neill, N. Parker, D. Roach, D. Rubin, D. Suich, P. VanderHorn, D. Voehringer, K. Voss, T. Yang; Systems Integration, Cell Biosciences, Palo Alto, CA

The ability to assay low abundance proteins in stem cells and other precious biological materials (primary cell lines, repeat sampling in animal models, tissue microdissections, etc.) is a critical need of life science research. In spite of a proliferation of new methods, the arduous Western blotting technique remains the most commonly utilized protein assay method. Using the fundamental strengths of Western blotting - the combination of a physical separation with antibody binding and signal amplification - we have developed a high performance, automated nano-volume immunoassay platform. Advantages of this system include high sensitivity (e.g. < 1000 stem cells), quantitative analysis and full automation. Additionally, the system performs separation and single antibody detection of phosphorylated and non-phosphorylated protein isoforms enabling insights into cell signaling previously unachieved. To meet these goals, a capillary electrophoresis platform incorporating a unique concept of locking proteins in place following a charge-based separation was developed. After protein separation and capture, antibodies are flowed through the capillary where they bind to their target proteins. In the standard method, primary antibodies are then bound by secondary antibodies with attached chemiluminescence reporter enzymes. Finally, whole capillary images are captured while chemiluminescent substrate is flowed through the capillary providing continuous luminescence detection without exhaustion of substrate. The system processes multiple capillaries in parallel similar to multiple lanes of a traditional Western analysis. Automation allows the unattended analysis of a full 96-well plate of samples in approximately 4 hours. The platform design is fundamentally scaleable to extremely high throughput capability similar to the evolution of modern DNA sequencers.

710

**Over a Hundredfold Increase in Immunoblot Signals of Laser-microdissected Inclusion Bodies with an Excessive Aggregation Property by Oligomeric Aip2p/Dld2p**

N. S. Hachiya,[1] T. Ohkubo,[2] Y. Kozuka,[3] Y. Sakasegawa,[4] K. Kaneko[1]; [1]Second Department of Physiology, Tokyo Medical University, Tokyo, Japan, [2]Department of Neurology and Neurological Science, Tokyo Medical and Dental University, Tokyo, Japan, [3]National Center of Neurology and Psychiatry (NCNP), Tokyo, Japan, [4]Department of Prion Protein Research, Tohoku University, Tokyo, Japan

By utilizing non-chemical denaturant (oligomeric Aip2p/Dld2p) with a combinatorial method of laser-microdissection and immunoblot analysis, we have established a histobiochemical apporoach targeting micron-order inclusion bodies with an extensive aggregation property *in situ*. As a model, pick bodies were chosen and laser-microdissected from 3 different brain regions of 2 patients with Pick's disease. Five hundred to 2,000 pick bodies were initially applied onto SDS-PAGE gels after boiling in Laemmli's sample buffer according to the established immunoblotting procedure, but only faint signal was obtained. Following negative results with chemical denaturants or detergent including 6 M guanidine hydrochloride, 8 M urea, and 2 % SDS, the laser-microdissected pick bodies were pretreated with oligomeric Aip2p/Dld2p, which exhibits a robust protein unfolding activity in biological condition. Strikingly, only one pick body was sufficient to illustrate an immunoblot signal, indicating that the pretreatment with oligomeric Aip2p/Dld2p enhanced the immunoblot sensitivity over a hundredfold. The pretreatment with oligomeric Aip2p/Dld2p also allowed us to quantify the total protein contents of pick bodies. Such unprecedented property of the oligomeric Aip2p/Dld2p may imply further potential applications. For example, a number of proteomic strategies rely on liquid chromatography-tandem mass spectrometry (LC-MS/MS), but sample preparation methods typically involve the use of detergents and chaotropes that often interfere with chromatographic separation and/or electrospray ionization. The oligomeric Aip2p/Dld2p, however, does not interfere with the LC-MS/MS procedures, and it could be an ideal pretreatment. Overall, oligomeric Aip2p/Dld2p may greatly facilitate the nano-scale analyses, which are often hindered from the aggregation property of target proteins in various protein analytical procedures, especially in minor quantities.

711

**Co-Detection of Low-Abundant Proteins in Signal Transduction Pathways**

S. Edlund,[1] J. Lennartsson,[2] M. Landstrom,[2] A. Edman-Örlefors,[1] A. Hagner-McWirther,[1] A. Hyuronowitz,[1] O. Ronn[1]; [1]Bio-Sciences, GE Healthcare, Uppsala, Sweden, [2]Ludwig Institute for Cancer Research, Uppsala, Sweden

Detection of proteins using Western blotting is a well known technique, most often based on chemiluminescense. A limitation is that only one antigen at a time can be detected. A stripping procedure has to be performed on the membrane before probing for the next protein. This will result in loss of material and reduced reliability of quantitations. Studies on low-abundant proteins, e.g. phosphoproteins, depend on reliable quantitative analysis methods. For this purpose a new Western blotting technique, based on antibodies conjugated with fluorescent molecules, has been developed and optimized. This enables simultaneous detection of two proteins or protein states (e.g. phospho- versus total protein levels) on the same membrane. Together with an increased dynamic range and high sensitivity this gives more reliable quantitations and reduced variability of activated low abundant proteins, like phosphoproteins. In this study we have been able to study proteins involved in signaling pathways that regulate cell growth, survival, actin reorganization, migration, differentiation and apoptosis, in response to the extracellular proteins platelet-derived growth factor (PDGF) and transforming growth factor beta (TGF-ß). We could detect the tyrosine phosphorylation of the PDGF receptor upon PDGF-BB stimulation of porcine aortic endothelial (PAE) cells. The simultaneous protein blot detection was done using primary antibodies for the phosphotyrosine protein which could be related to the total receptor levels (PDGFR-β) by using multi-wavelength fluorescent secondary antibodies. We could also detect and make accurate quantifications of the TGF-β-mediated phosphorylation of p38 in human T293 epithelial kidney cells. Here, human T293 epithelial kidney cells were activated with TGF-β and harvested at different time points. The TGF-β-mediated

phosphorylation of p38 shows proportional increase, of pp38, when compared to actin.

712

**Improvement in Large-scale Production of PCR-generated Small DNA Fragments for a Gene Therapy Approach**

D. de Semir; CPMC, San Francisco, CA

Background: One novel gene therapy repair strategy, Small Fragment Homologous Replacement (SFHR), uses small DNA fragments (SDFs) generated by PCR and has demonstrated its effectiveness in altering gene sequences both *in vitro* and *in vivo*. A necessary factor to improve the efficiency of SFHR-mediated gene modification requires the establishment of a protocol for the production of large-scale SDF of good quality. Objective: Validation of a method to produce large quantities of SDFs not exposed to UV light nor to ethidium bromide (EtBr) for electroporation into two human lymphoblastoid cell lines containing a point mutation on exon 5 and 6 of the interleukin-2 receptor common gamma chain gene (*IL2RG*). Methods**:** Various SDFs differing in size including the wild-type *IL2RG* gene sequence were amplified by PCR from genomic DNA isolated from a non-SCID cell line and cloned. The clones sequenced were used as a template for large-scale generation of SDFs containing the wild-type sequence. The pooled DNA fragment was ethanol precipitated, quantified spectrophotometrically, and purified by gel extraction. However, only the lane containing a small sample of the pooled DNA was stained with EtBr and visualized by UV. The remaining pooled DNA fragment was sliced out of the gel based on the position of this visualized reference sample. Studies are now underway to evaluate the efficacy of the transfected SDFs. Results**:** a large amount of SDFs not exposed to EtBr nor to UV can be obtained by gel extraction purification. Conclusions: the non use of UV nor EtBr increases the purity and quality of the PCR-generated SDF for gene therapy approaches as it doesn´t contain possible T-T adducts created by UV nor intercalating agent in its sequence, then reducing its toxicity when transfected into target cells.

713

**Targeted Disruption of Transcriptional Regulatory Function of p53 by a Novel Efficient Method for Introducing a Decoy Oligonucleotide into Nuclei**

T. Nukui,[1] M. Sakaguchi,[1] H. Sonegawa,[1] H. Murata,[2] J. Futami,[2] H. Yamada,[2] N. Huh[1]; [1]Department of Cell Biology, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Shikatachou, Okayama, Japan, [2]Department of Bioscience and Biotechnology, Okayama University Graduate School of Natural Science and Technology, Tsushimanaka, Okayama, Japan

Decoy oligonucleotides have been used for functional sequestering of transcription factors. Efficient introduction into cells is a prerequisite for the oligonucleotides to exert their blocking function. Lipofection is the most widely used technique for that purpose because of its convenience and relatively high efficiency. However, the transduction efficiency of lipofection largely depends on cell-types and experimental conditions and the introduced nucleotides are not specifically directed to nuclei where they exert their major function. In the present study, we designed a new system for transporting oligonucleotides into cell nuclei. The vehicle is composed of glutathione-S-transferase, 7 arginine residues, the DNA-binding domain of GAL4, and a nuclear localization signal, which are linked with flexible glycine stretches. The p53 responsive element linked to the GAL4 upstream activating sequence was efficiently transferred by the vehicle protein into nuclei of primary cultures of neuronal cells, ES cells and various human normal cells. Transcriptional activation of $p21^{WAF1/CIP1}$ and Bax by p53 on exposure to cisplatin was completely blocked by introducing the p53 decoy oligonucleotide. Thus, the system developed in the present study can be a convenient and powerful tool for specifically disrupting the function of DNA binding proteins in culture.

714

**Adenoviral-mediated Transgene Expression Enhanced by Etoposide Co-treatment in Cultured Cells**

J. W. Triplett, B. P. Herring, F. M. Pavalko; Cellular and Integrative Physiology, Indiana University School of Medicine, Indianapolis, IN

The overexpression of proteins in cell culture systems is an effective way to assess the function of proteins in cells. In recent years, the development of adenoviral-mediated gene transfer systems has enhanced the ability of researchers to express exogenous proteins to a high level in multiple cell types. However, expression in certain cell types and expression of certain constructs remains difficult even with adenoviral-mediated gene transfer. We investigated the potential of the topoisomerase inhibitor etoposide to increase adenoviral-mediated gene expression in cell culture systems. Previous studies indicate that the use of DNA-damaging agents, such as topoisomerase inhibitors, may increase adeno-associated viral-mediated transgene expression both *in vivo* and *in vitro*. Titration of etoposide in the presence of equal volumes of adenovirus demonstrated that treatment with as little as 100 nM etoposide for the first 24 hours of infection increases transgene expression up to 3-fold in both UMR106 and REF52 cells. Importantly, subsequent studies indicated that low doses of etoposide did not cause cytotoxicity, as measured by lactate dehydrogenase release, nor apoptosis, as measured by western blotting for apoptotic markers. Additionally, equivalent transgene expression was achieved using approximately five-fold less volume of virus. Finally, the use of etoposide did not interfere with the ability of exogenous proteins to function normally within cells, as evidenced by the ability of myocardin to increase smooth muscle-specific protein expression in osteosarcoma-like cells even in the presence of etoposide. Together these data indicate that etoposide may be an effective means to enhance the expression of adenoviral constructs in several cell types without inducing cytotoxic nor apoptotic effects. The use of etoposide may be an inexpensive way to both increase adenoviral transgene expression in cultured cell systems and prolong the life of adenoviral stocks.

715

**Generation of a Cre/LoxP-based Conditional hCXCR1 Transgenic Mouse Line with Color-Switching Indicators to Study the Functions of hIL-8 *in vivo***

L. Zheng, M. Martins-Green; Department of Cell Biology and Neuroscience, University of California, Riverside, CA

The CXC chemokine Interleukin-8 (IL-8) plays pivotal roles in inflammation, wound healing and angiogenesis. Human IL-8 has two 7-transmembrane G-protein-coupled-receptors, CXCR1 and CXCR2, both of which mediate the functions of IL-8 in human but in different ways. We used a Cre/LoxP-based transgenic vector to introduce hCXCR1 into mice, which enables controlled expression of hCXCR1 in both location and time. The C-terminus of hCXCR1-ORF was fused to the tetracysteine (C4) motif, which serves as binding motif for biarsenical fluorescent reagents for *in situ* labeling of recombinant protein in live cells. A fusion protein of firefly luciferase and eGFP (Luc-eGFP) was designed to target onto the plasma membrane with eGFP on the outside and the luciferase moiety inside. This will facilitate tracing of cells *in vivo* and cell separation

*in vitro*. The ORFs for hCXCR1-C4 and Luc-eGFP were incorporated into an IRES-based bicistronic transcript driven by a potent and ubiquitous promoter that is active in all mouse tissues. A floxed monomeric red fluorescent protein (mRFP) ORF+3xPolyA was inserted between the promoter and the bicistronic transcript to render the hCXCR1 expression silent in the F1 founder mice. When these mice are crossed with Cre-recombinase expressing mice, the mRFP1+3xPolyA is deleted and the hCXCR1-C4 and Luc-eGFP expression are activated. Tissue-specific and other cre-mice will facilitate various ways of hCXCR1 targeting by crossing with the F1 founder mice. This transgenic hCXCR1 mouse line can be a useful system to study IL-8's function *in vivo*, and the transgenic vector used here can also be a generic transgenic vector to deliver other genes of interest, providing several useful features for biological manipulations and imaging.

716

**Bacteriophage Recombinase Stimulates Single-strand DNA Oligonucleotide-mediated Gene Targeting in Human Cells**

K. Xu,[1] A. Stewart,[2] A. C. Porter[1]; [1]Department of Hematology, Imperial College London, London, United Kingdom, [2]Genomics, University of Technology, Dresden, Germany

Gene targeting uses homologous recombination (HR) to create defined changes in cellular DNA with great specificity and flexibility. This can be achieved by use of double-stranded DNA (dsDNA) gene targeting vectors or single-strand DNA oligonucleotides (ssODN) to introduce the desired changes. The efficiency of these processes is low, and improvements are required if genome modification is to be fully exploited as a tool in cell biology or as a form of gene correction therapy. In *Escherichia coli*, bacteriophage recombination systems (Redα/Redβ or RecE/RecT) have been used successfully to modify both plasmid and chromosomal DNA in a highly efficient manner, using either a linear dsDNA fragment or a ssODN. In this study, we have established human HT1080 cell lines with tightly regulated Redβ expression, and Redβ localized in nuclei. We find that Redβ stimulates homologous recombination between co-transfected plasmids and both dsDNA- and ssODN-mediated gene targeting ~2-fold. We also show that transient depletion of the mismatch repair protein MSH2, by RNA interference, stimulates ssODN-mediated episomal gene targeting ~2-3-fold. We show further that Redβ expression and MSH2 depletion can be combined to stimulate episomal gene targeting ~ 6-fold. These studies therefore describe new ways to improve gene targeting efficiencies. We are currently investigating whether the effects of Redβ expression can be stimulated by co-expression of Redα. Future optimisation and combination of these and related approaches may facilitate the generation of mutant cell lines and the therapeutic repair of mutated disease genes.

**Design of a Quantitative Method for Detection of Allele-specific RNA Expression**

E. D. Klootwijk, P. J. Savelkoul, C. Ciccone, D. M. Krasnewich, W. A. Gahl, M. Huizing; NHGRI, NIH, Bethesda, MD

Hereditary Inclusion Body Myopathy (HIBM) and sialuria are two distinct disorders resulting from mutations in the same gene, *GNE*, coding for the bifunctional, rate-limiting enzyme in sialic acid biosynthesis, i.e., UDP-GlcNAc 2-epimerase (GNE)/ManNAc kinase (MNK). Sialuria is caused by dominant mutations in the allosteric site of GNE/MNK, leading to a loss of feedback-inhibition and increased sialic acid excretion. In contrast, HIBM is caused by recessive *GNE* mutations outside the allosteric site, resulting in decreased GNE/MNK enzyme activity and decreased sialic acid production. Both sialuria and HIBM exhibit variable clinical phenotypes. We examined if mutation-dependent variations in allelic expression of *GNE* could account for the variable disease phenotypes. We developed a real-time RT-PCR method that rapidly and accurately detects and quantifies allele-specific expression. The procedure is based on the use of a combination of two allele-specific fluorescent reporter probes and real-time amplification kinetics. We first tested the validity of each allele-specific assay across a concentration range obtained by mixing cell-free transcribed normal and mutated *GNE* RNA. Each of the assays proved to be accurate and mutation-specific, allowing us to study allelic expression of *GNE*. We applied the assays to RNA obtained from fibroblasts of sialuria or HIBM patients. No patient showed a significant difference in mutation-dependent allelic *GNE* expression, indicating that allelic expression did not cause the variable phenotypes in these patients with sialuria or HIBM. This novel, allele-specific RNA quantifying method is convenient and rapid, and requires minimal concentrations of RNA (<25ng). The procedure is attractive for various applications, including validation of SI-RNA silencing experiments. In fact, we have demonstrated the method's validity for allele-specific RNA gene silencing using SI-RNAs in sialuria fibroblasts. In addition, this method can be employed for studies of X-chromosomal inactivation, genetic imprinting, and epigenetics.

**Method Development and Optimization for Automated Fluorescent (Q-DOT®) In-Situ Hybridization**

A. Birmingham,[1] L. K. Samadzadeh,[1] K. A. Vanpatten,[1] K. Hopkins,[1] A. Sattler,[1] C. Bauer,[1] C. Beinarz,[1] P. J. Beresford,[1] T. M. Grogan,[1] R. B. Nagle,[2] P. Miller,[1] G. A. Pestano[1]; [1]Discovery, Ventana Medical Systems, Tucson, AZ, [2]Pathology, University of Arizona Cancer Center, Tucson, AZ

The ability to rapidly detect genetic abnormalities has become increasingly important following the sequencing of the human genome. The recognition of genetic links to human disease states in oncology clearly illustrates the need for novel diagnostic applications. Candidate diagnostic tests need not only be reproducible, but also developed with a high degree of sensitivity. In addition, the complexity of the gene-linked diseases has resulted in the need to simultaneously monitor multiple markers. The objective of this study was to apply our automated methods to the development of ISH protocols that may be rapidly delivered and conducted reproducibly, in a highly sensitive manner. A matrix of conditions was tested for developing ISH applications. The candidate test for the development matrix was to detect the epidermal growth factor receptor (EGFR) gene in formalin-fixed and paraffin-embedded (FFPE), cell lines and in tissues. EGFR gene amplification has been linked to disease progression in a number of studies. Detection was conducted in positive controls, including in head and neck cancer and in normal skin, with a chromogenic assay (CISH) and validated in a separate Quantum Dot (QDot®) application. We report a matrix of conditions that may be used to rapidly develop a new ISH procedure in less than 72 hours. The EGFR ISH protocol was highly reproducible in both normal and neoplastic tissues, sensitive to single gene-copy detection, and amenable to archiving. The disclosed method of assay development will be highly relevant for the detection of aberrant gene and protein regulation events.

### An ELISA Based Rho Activation Assay

L. Cheng, K. M. Middleton, A. S. Davis; Cytoskeleton Inc, Denver, CO

The Rho family of small GTPases consists of at least 20 members, the most extensively characterized of which are the RhoA, Rac1 and Cdc42 proteins. In common with other small GTPases, the Rho proteins act as molecular switches that transmit cellular signals through downstream effector proteins by alternating between active GTP-bound and inactive GDP-bound states. The Rho family mediates a wide range of cellular responses, including cytoskeletal reorganization, regulation of transcription, membrane trafficking and apoptosis. Therefore, understanding the mechanisms that regulate activation and inactivation of the GTPases is of great biological significance and is a subject of intense investigation. The fact that Rho family effector proteins will specifically recognize the GTP-bound form of the protein has been used to develop affinity purification assays to monitor Rho protein activation. Traditionally, this has been done by coupling Rho binding domains (RBD) of Rho effector proteins to agarose beads, which are used to precipitate the active Rho from a biological sample. However, this method suffers from being time-consuming, requiring large amount of sample, yielding inconsistent results and not being suitable to high throughput screens. To avoid these drawbacks, we have developed an ELISA based assay to detect Rho activation. This novel Rho activation assay uses a 96-well plate coated with RBD domain of Rho effector proteins. The active Rho, but not inactive Rho, from a biological sample will bind to the plate. Bound active Rho is detected by incubation with an anti-Rho antibody followed by a secondary antibody conjugated to HRP and chemiluminescence. This ELISA based method is simple, fast, requires only small amounts of sample and yields quantitative and consistent results. It will therefore be a powerful tool to investigate Rho activation.

721

### Study Denitrifying Bacteria in Marine Sediments by In-Situ RT-PCR

G. Toro, G. Rodriguez, E. Padilla, E. Perez, A. Massol; Biology Department, University of Puerto Rico, Mayaguez, PR

The constant development of molecular techniques for the identification of bacteria in environmental samples is essential for understanding the interactions and roles of microbes in nutrient cycling. In situ Reverse Transcription PCR (RT-PCR) has become a novel technique to study gene expression. We are applying this approach to study the expression of the nirS gene in denitrifying bacteria. Pure cultures of model denitrifying isolates from Puget Sound marine sediments were used to optimize the RT-PCR protocol and we are now applying this technique directly from environmental samples. In order to ensure the presence of active denitrifying populations, marine sediments were bioaugmentaded with Paracoccus denitrificans and biostimulated with a nitrate solution. Unamended sediments were used as reference samples. After 48 hours of incubation, cells were extracted in a Phosphate/Tween 80 solution, filtered and concentrated by centrifugation. Samples were fixed with RNase free 4% paraformaldehyde and RNAprotect™Bacteria Reagent. Subsequently, cells were enzymatically permeabilized with lyzozyme and Proteinase K and spotted on microscope slides. In situ RT-PCR was performed using the QIAGEN® OneStep RT-PCR Kit. Amplification of cDNAwas performed using the nirS 1F and nirS 6R primers followed by Fluorescent In Situ Hybridization (FISH). A Cy-3 labeled internal oligonucleotide probe designed to detect the nirS gene in Pseudomonas stutzeri was used to specifically detect the gene of interest. Slides were then examined by fluorescence microscopy. Detectable cells were obtained from all marine sediments but at higher frequencies in bioaugmentated/ biostimulated systems. The outcomes obtained provide the basis for rapid detection of specific microorganisms in environmental samples without the need of cultivation or even nucleic acid isolation in marine sediments.

### A Novel Multiplex-like ELISA Test Reveals that both Gla-Clotting and Anti-Calcification Proteins are Present on Calcifying Nano-Particles

K. M. Aho,[1] O. E. Kajander,[2] N. Ciftcioglu[3]; [1]Department of Biochemistry, University of Kuopio, Kuopio, Finland, [2]Nanobac Life Sciences, Tampa, FL, [3]NASA Johnson Space Center, Houston, TX

OBJECTIVE Calcifying Nano-Particles (CNP), also called Nanobacteria, are tiny particles in blood with the ability to form apatite on them. Our studies on biodistribution of CNP revealed that colloidal CNP caused arterial and venous thrombosis in a significant number of rabbits and rats within minutes after i.v. administration. Our aim was to determine why CNP enchance blood clotting/thrombosis. A novel Multiplex ELISA was developed to probe with specific antibodies the possible presence of Gla-proteins, having high binding affinity towards apatite, on CNP. METHODS CNP were detected with quantitative Nanocapture ELISA kit (Nanobac Oy, Finland). The capture antibody was replaced with several specific anti-Gla-protein antibodies, including antibodies for blood clotting factors FII, FVII, FIX and FX/Xa and blood anti-mineralization proteins. The same detection antibody from the Nanocapture kit was used in all tests and plasma and serum gave comparable results. 16 pooled human serum samples (2 negative and 14 positive representing CNP values from 0 to 640 Capture units) were assayed with all capture antibodies. Correlation values between Nanocapture and various Multiplex ELISA variants were determined with Pearson Correlation Coefficients. RESULTS Pearson Correlation Coefficients indicated presence of all clotting Gla-proteins and matrix-Gla protein in CNP. The pattern of their presence correlated with Capture unit results for CNP ($p < 0.001$ for all of them). CONCLUSIONS Multiplex ELISA proves that the human blood CNP contain FII, FVII, FIX, FX/Xa and matrix-Gla protein. Likely binding mechanism to CNP is the high affinity of their multiple Gla-residues to apatite. Thus CNP particles have their own coagulation system in addition to anti-calcification system. The Multiplex ELISA is suitable for detecting the Gla-proteins and other proteins on CNP, and provides a novel type of assay for analyzing CNP pathological proteins.

### Sphingosine 1-phosphate Signaling in the Vascular System

T. Hla; Center for Vascular Biology, Univ of Connecticut Health Center, Farmington, CT

Metabolism of sphingomyelin, an abundant membrane phospholipid by the sphingomyelinase pathway results in the formation of sphingosine 1-phosphate (S1P), a pleiotropic lipid mediator. Our laboratory has shown that S1P acts via the G protein-coupled receptors of the EDG family, which are renamed as S1P1-5 receptors. S1P receptors are present in vertebrates and regulate vascular development, angiogenesis and immune cell

trafficking. In mammals high plasma S1P and low tissue S1P levels establish a vascular S1P gradient. The cellular basis of this gradient is not clearly understood. Sphingosine kinase-1a isoform is secreted from vascular endothelial cells and contribute to the high plasma S1P levels. Different sphingosine kinase isoforms are localized at different subcellular locales and produce S1P, suggesting that site-specific formation of S1P is critical for various biological activities of this lipid mediator. In the vascular system, S1P1 receptor activates the PI-3-kinase/ Akt pathway to regulate endothelial cell migration and adherens junction assembly. The small GTPase Rac is critical for this receptor to activate the actin- and microtubule cytoskeleton dynamics. In contrast, the S1P2 receptor antagonizes this pathway by activating the small GTPase Rho/ and Rho-associated kinase (ROCK). Ultimately, this pathway induces the tumor suppressor phosphatase PTEN to inhibit cell migration and adherens junction assembly. Therefore, S1P receptors coordinately regulate angiogenesis and vascular permeability. In addition, mural cell recruitment to nascent vascular sprouts is also regulated by S1P1 signaling in vascular endothelial cells. Further understanding of S1P biology and signaling may avail novel therapeutic approaches in the control of vascular diseases.

**Protease-activated Receptors Play a Role in Intracellular $Ca^{2+}$ Dynamics of Arteriole Smooth Muscles of Brain**

Y. Satoh, T. Misaki, M. Matsuura, T. Saino, H. Akutsu-Yamauchi; Histology, Iwate Medical University, Morioka, Japan

[OBJECTIVE] Protease-activated receptors (PARs) mediate cellular responses to various proteases in diverse cell types, including smooth muscles and endothelium of blood vessels. PARs may play important roles in microcirculation in the tissue/organs. Here we examine whether stimulation of PARs induce responses of smooth muscles of arterioles. [MATERIALS AND METHODS] Arterioles (< 100 µm in diameter) were taken from brain and testis of rats. Isolated and cultured smooth muscles alter essential characteristics, therefore we used arteriole specimens which kept essential structural integrity. Intracellular $Ca^{2+}$ ($[Ca^{2+}]_i$) dynamics and nitric oxide (NO) production during PARs stimulations were evaluated by confocal microscopy (Nikon RCM/Ab), because $[Ca^{2+}]_i$ and NO are key factors in the maintenance of strain in blood vessels. [RESULTS] Thrombin and PAR1-agonist peptide (AP) induced oscillatory fluctuations of $[Ca^{2+}]_i$ of brain arteriole smooth muscles. The response was independent of extracellular $Ca^{2+}$, but depletion of intracellular $Ca^{2+}$ store suppressed the response. Small arterioles (< 50 µm in diameter) showed conspicuous oscillations, but larger those not. Any changes of endothelium were not verified. Trypsin and PAR2-AP induced faint oscillatory fluctuations and evident decrease of $[Ca^{2+}]_i$ level. It might be possible that activation of PAR2 induce NO production of endothelium, which in turn depressed $[Ca^{2+}]_i$ level of smooth muscle. However, NO production during PAR2 stimulation was not detected, and NO-synthase inhibitor did not suppressed PAR2 -AP induced $[Ca^{2+}]_i$ decrease. NO showed no decrease of $[Ca^{2+}]_i$ level. PAR3- and PAR4-AP had no effect. In contrast to brain arterioles, smooth muscles of testicular arterioles showed neither oscillatory fluctuations during PAR1 activation nor decrease of $[Ca^{2+}]_i$ level during PAR2 stimulation. [CONCLUSION] Proteases in various pathological conditions control microcirculation via PARs of arteriole smooth muscles in a NO-independent manner, although there may be organ-specificity.

**7-Ketocholesterol Predisposes Human Aorta Smooth Muscle Cell to Fas-mediated Death**

K. Kim, B. Rhim; Department of Pharmacology - School of Medicine, Pusan National University, Busan, Republic of Korea

Human vascular smooth muscle cells (HVSMCs) are resistant to Fas-mediated death under normal physiological conditions. However, HVSMC death by activation of the receptor pathway was reported in the atherosclerotic lesions. In this study, we investigated whether 7-ketocholesterol, one of the major cholesterol oxides in the lesions, altered resistance of HVSMC to Fas-mediated death pathway. Cross-linking of Fas receptor with agonistic anti-Fas antibody (CH11) in the presence of 7-ketocholesterol induced death in human aorta smooth muscle cells (HAoSMC) as detected by morphology, viability, and DNA fragmentation. The agonistic anti-Fas antibody, however, did not induce death in the presence of 7α-hydroxycholesterol or cholesterol. The HAoSMC death was significantly inhibited by an antagonistic Fas receptor (FasR) antibody and by expression of dominant negative Fas-associated death domain containing protein (DN-FADD) using adenoviruses. Activation of caspase-8 and -3 was observed in HAoSMC destined to death. HAoSMC death was significantly inhibited by pharmacological caspase inhibitor, z-VAD and z-DEVD, and baculovirus caspase inhibitor p35. Overexpression of bcl-xL also significantly inhibited HAoSMC death. The levels of Fas, FADD, caspase-8, caspase-10, caspase-3, caspase-9, c-FLIP, bax and XIAP were not changed in response to 7-ketocholesterol, whereas 7-ketocholesterol impaired mitochondrial transmembrane potential and ATP production. In dying HAoSMC, bax was translocated from the cytosol to mitochondria and cytochrome c was released from mitochondria into the cytosol. This is the first report demonstrating implication of the oxysterol in Fas-mediated death pathway. The present study proposes that 7-ketocholesterol would contribute to loss of HVSMC in the atherosclerotic lesions by altering resistance to receptor-mediated death pathway.

726

**Polarized Vascular Smooth Muscle Cell Mitoses in Response to Mechanical Load**

D. Dajnowiec,[1] J. T. K. Lam,[1] B. L. Langille[2]; [1]Department of Laboratory Medicine and Pathobiology, University of Toronto, Toronto, ON, Canada, [2]Cell and Molecular Biology, Toronto General Hospital, Toronto, ON, Canada

Arteries are constantly adapting to changes in mechanical forces imposed on them; therefore, they provide an excellent model for studying tissue responses to mechanical forces. We previously showed that vascular smooth muscle cells (VSMC) of the arterial wall mediate homeostatic regulation of longitudinal tension and we therefore hypothesize that mechanical tension induces VSMC to undergo polarized mitoses such that daughter cells are delivered in the direction of stress. To test this hypothesis, a segment of the left carotid artery of New Zealand White rabbits was surgically excised, and the cut ends of the vessel were reattached. BrdU, to label S-phase nuclei, was injected into the rabbits at surgery or 3 or 7 days later. The rabbits were euthanized at 1, 3, or 7 days after surgery and the LCA were perfusion-fixed at 100 mm Hg. Whole-mount preparations of the stretched vessel segments were prepared for en face immunohistochemistry and nuclear counter-staining, and mitotic orientations of newly divided nuclei doublets were analyzed using Laser Confocal Microscopy and image analysis software. Labeled nuclear doublets were oriented perpendicular to the arterial axis in control and sham-surgery vessels. In contrast, over 50% of the VSMC doublets oriented along the longitudinal axis in surgically-stretched LCA. Hence, the data indicate that normalization of tensile stretch in arteries involves the delivery of daughter VSMC in the axial direction by tension-induced polarized mitosis. Subsequent alterations in orientation and separation of daughter cell nuclei indicated that polarized mitosis was followed by cell migration that further modified position of cells within the vessel wall.

727

**Embryonic Lethality in Mice with Endothelial and Smooth Muscle Cell-Specific Deletion of the Bone Morphogenetic Protein Type IA Receptor (BMPR-IA)**

N. El-Bizri,[1] L. Wang,[1] E. Martinez,[1] C. P. Chang,[2] Y. Mishina,[3] M. Rabinovitch[1]; [1]Pediatrics, Stanford University, Stanford, CA, [2]Cardiovascular Medicine, Stanford University, Stanford, CA, [3]Molecular Developmental Biology Group, Stanford University, National Institute of Environmental Health Science, NC

Bmpr1a expression is reduced in lungs of patients with pulmonary arterial hypertension. (PAH). To determine the role of Bmpr1a in the pathogenesis of PAH, we selectively deleted Bmpr1a in vascular endothelial (EC) and smooth muscle cells. We bred mice expressing floxed Bmpr1a and ROSA26 reporter with Tie2-Cre and SM22-Cre mice, respectively. Both Tie2/Bmpr1a and SM22a/Bmpr1a homozygous knockout (-/- K/O) mice die around E11.5. While the cause of lethality of SM22/Bmpr1a -/- K/O is yet to be determined, vascular defects in yolk sac and placenta underlie the lethality of Tie2/Bmpr1a -/- K/O. At E11.5, the yolk sac was pale and devoid of blood. However, at E10.5, H&E stained cross sections revealed early signs of a degenerating vasculature manifest by detachment of the EC layer from the mesoderm. At E11.5, fusion of large and collapse of small vessels with total absence of blood cells was observed. Failure of penetration of embryonic tissue into the labyrinth of maternal placenta and fewer embryonic vessels were signs of defective placenta at E11.5. The E10.5 -/- K/O showed intact vasculature judged by whole-mount LacZ and PECAM staining. At E11.5 there was retardation in development and occasional enlargement of the pericardial cavity with a hemorrhagic effusion. Serial transverse sections at E9.5 and E10.5 excluded cardiac defects. Knocking down Bmpr1a by 72 % using RNAi in human pulmonary artery EC resulted in an attenuated serum-induced proliferative response ($P < 0.01$) judged by MTT assay but had no significant impact on migration. In conclusion, EC expression of Bmpr1a is necessary for normal yolk sac vascular remodeling and the impaired ability of EC to proliferate appears to be the consequence of loss of function of Bmpr1a in development and disease.

728

**A Novel Role for Fra-1 in Thrombin-induced Vascular Smooth Muscle Cell DNA Synthesis and Motility**

H. Cao, G. N. Rao; Department of Physiology, University of Tennessee Health Science Center, Memphis, TN

In order to understand the mechanisms by which thrombin induces vascular smooth muscle cell (VSMC) DNA synthesis and motility, here we have studied the role of PI3K-Akt-mTOR-S6K1 signaling. Thrombin stimulated the phosphorylation of Akt and S6K1 in VSMC in a sustained manner. LY294002, a specific inhibitor of PI3K, completely suppressed both Akt and S6K1 phosphorylation, whereas rapamycin, a specific inhibitor of mTOR, blocked only S6K1 phosphorylation induced by thrombin, suggesting that thrombin activates the PI3K-Akt-mTOR-S6K1 signaling in this order in VSMC. Blockade of PI3K-Akt-mTOR-S6K1 signaling by LY294002 and rapamycin prevented both thrombin-induced VSMC DNA synthesis and migration. Adenoviral-mediated expression of dominant negative Akt also inhibited thrombin-induced VSMC DNA synthesis and migration. Furthermore, thrombin induced the expression of Fra-1 in a sustained and PI3K/Akt-dependent and mTOR/S6K1-independent manner in VSMC. Suppression of Fra-1 by its siRNA attenuated both thrombin-induced VSMC DNA synthesis and migration. In addition, thrombin stimulated the tyrosine phosphorylation of epidermal growth factor receptor and inhibition of its kinase activity significantly blocked thrombin-induced Akt and S6K1 phosphorylation, Fra-1 expression and DNA synthesis in VSMC and their motility. Together, these observations suggest that thrombin induces both VSMC DNA synthesis and motility via EGFR-dependent stimulation of PI3K/Akt signaling targeting in parallel the Fra-1 expression and S6K1 activation.

729

**Examination of Endothelial Lumenization Processes *in vivo* Using Zebrafish *Danio rerio***

M. Kamei,[1] K. J. Bayless,[2] G. E. Davis,[2] B. M. Weinstein[1]; [1]LMG, NICHD/NIH, Bethesda, MD, [2]Department of Pathology and Laboratory Medicine, Texas A&M University System Health Science Center, College Station, TX

The process of vascular lumen formation has previously been studied in cultured endothelial cells *in vitro*. It has been shown that endothelial lumen formation occurs through accumulation of pinocytic vacuoles and their subsequent intra- and intercellular fusion . However, the relevance of data obtained through cell culture studies has not been tested in live animals before. Towards this end, we have prepared *Tg(fli1:cdc42wt-EGFP)* germline transgenic zebrafish in which a cdc42wt-EGFP fusion protein is expressed in endothelial cells *in vivo* under the control of the zebrafish *fli1* promoter. This *cdc42wt-EGFP* construct we used was previously shown to visualize vacuoles in endothelial cells in culture . We have shown that within *Tg(fli1:cdc42wt-EGFP)* zebrafish the cdc42wt-EGFP protein similarly localizes preferentially to the surface of cytoplasmic vacuolar structures. By using this transgenic line, we have captured dynamic images *in vivo* of lumenization of the developing blood vessel. The images show that the cytoplasmic vacuolar structures coalesce into the mature vascular endothelial lumen *in vivo.* These images suggest that lumenization *in vivo* also occurs in a very similar manner to that of the vacuole formation and fusion process shown *in vitro*. References

**Role of Hepatocyte Growth Factor (HGF) in Expression of Proteases and Cell Migration during Retinal Neovascularization**

E. Colombo; Cell Biology and Physiology, University of New Mexico, School of Medicine, Albuquerque, NM

**Purpose:** Hepatocyte growth factor (HGF), and its receptor, c-met, are known to promote cell migration. They have been implicated in the progression of angiogenesis in many cancer models and are upregulated in diabetes. However, HGF mediation of protease expression and endothelial cell migration and invasion in the diabetic retina has not been explored. We determined if HGF affects cell migration and protease levels in retinal microvascular endothelial cells and in a mouse model of retinal neovascularization. **Methods:** Bovine retinal microvascular endothelial cells (BRMVEC) were stimulated with HGF (10ng/ml). At 24 hours, conditioned media and cell extracts were collected and analyzed by zymography or by reverse-transcription PCR. Migration and invasion assays were performed with BRMVEC's grown on migration chambers with or without Matrigel. HGF or VEGF was used in the bottom chamber as a chemoattractant. After 24 hours, the amount of migration into the lower chamber was analyzed. Retinal neovascularization was induced in newborn mice by exposure to 75% oxygen followed by room air. Eyes were collected at day 17 following removal from high oxygen, fixed, and paraffin embedded. Immunohistochemistry was performed on sections to localize retinal c-met expression. **Results:** After 24 hours of HGF stimulation, there was a significant increase in endothelial cell expression of urokinase. PCR analysis of uPA and uPAR mRNA showed a similar expression pattern. Migration and invasion assays demonstrated that HGF

significantly increased BRMVEC cell migration and invasion compared to VEGF samples. Immunohistochemical staining showed localized c-Met expression in the retina, which was increased in experimental animals compared to control. **Conclusion:** HGF, acting through its receptor c-met, may play an important role in the initial stages of retinal angiogenesis by stimulating a migratory phenotype and endothelial cell protease production.

731

## Low-dose Irradiation Promotes Tissue Revascularization Through VEGF Release from Mast Cells and Mmp-9 Mediated Progenitor Cell Mobilization

B. Heissig,[1] H. Akiyama,[1] S. Rafii,[2] Z. Werb,[3] K. Hattori[1]; [1]Stem Cell Regulation, Center of Experimental Medicine, University of Tokyo, Tokyo, Japan, [2]Dep. of Hematology-, Cornell University, Tokyo, Japan, [3]Dep. of Anatomy, University of California, San Francisco, CA

Mast cells accumulate in tissues undergoing angiogenesis during tumor growth, wound healing, and tissue repair. Mast cells can secrete angiogenic factors such as vascular endothelial growth factor (VEGF). Ionizing irradiation has angiogenic potential in malignant and non-malignant diseases. We observed that low-dose irradiation fosters mast cell-dependent vascular regeneration in a limb ischemia model. Irradiation promoted VEGF production by mast cells in a matrix metalloproteinase-9 (MMP-9) dependent manner. Irradiation, through MMP-9 upregulated by VEGF in stromal and endothelial cells, induced the release of Kit-ligand (KitL). Irradiation-induced VEGF promoted migration of mast cells from the bone marrow to the ischemic site. Irradiation-mediated release of KitL and VEGF was impaired in MMP-9 deficient mice resulting in a reduced number of tissue mast cells and delayed vessel formation in the ischemic limb. Mast cell deficiency steel mutant ($Sl/Sl^d$ mice) or blockade of the VEGF pathway abrogated irradiation-induced vasculogenesis. Irradiation did not induce progenitor mobilization in $Sl/Sl^d$ mice. We conclude that increased recruitment and activation of mast cells following irradiation alters the ischemic microenvironment and promotes vascular regeneration in an ischemia model. These data show a novel mechanism of neovascularization and suggest that low-dose irradiation may be used for therapeutic angiogenesis to augment vasculogenesis in ischemic tissues.

732

## Signal Transduction Pathways Stimulated by Multiple Angiogenic Factors Result in Activation of SREBPs-HMGCoA-RhoA

M. Yao, R. Zhou, M. Petreaca, M. Martins-Green; Cell Biology & Neuroscience, UCR, Riverside, CA

Angiogenesis is essential in many physiological and pathological processes. Therefore, to better understand the angiogenic process and to more efficiently manipulate it, it is important to identify common signaling pathways stimulated by different angiogenic factors. Sterol regulatory element-binding proteins (SREBPs) are transcription factors regulating the metabolism of cholesterol and fatty acids, which are critical in membrane biology and signal transduction. In previous studies, we have shown that VEGF activation of SREBPs plays a key role in angiogenesis. In this study, using human microvascular endothelial cells (hMVEC) and the Chorioallantoic membrane (CAM) assay, we further show that angiogenic factors belonging to different families, such as bFGF, thrombin, and IL-8, also stimulate SREBP activation despite their activation of disparate classes of receptors (bFGF through tyrosine kinase receptors, IL-8 and thrombin through G-protein-coupled receptors). In contrast non-angiogenic factors, such as TGFβ1, do not. This activation of SREBPs is critical in permeability of the endothelium and in endothelial cell migration, as well as IL-8-induced angiogenesis *in vivo*. Furthermore, we explored the underlying mechanism and found that the effects of SREBPs on angiogenesis stem, at least in part, from their regulation of RhoA geranylgeranylation by geranylgeranyl pyrophosphate (GGPP), a product downstream of 3-hydroxy-3-methylglutaryl coenzyme A (HMGCoA) during cholesterol biosynthesis. Taken together, our data suggest that the HMGCoA-RhoA activation is one of the signal transduction events occurring downstream of SREBP in the angiogenesis induced by two very different angiogenic factors, IL-8 and VEGF. Given that diverse angiogenic factors use different types of cell-surface receptors, identification of this common signal transduction pathway as a target could provide the opportunity for novel approaches to the prevention and treatment of diseases involving abnormal angiogenesis.

## Hepatic Stellate Cells in Arctic Top Predators

H. Senoo,[1] K. Wake,[2] H. L. Wold,[3] N. Kuwata-Higashi,[1] T. Irie,[1] K. Yoshikawa,[1] J. Ø. Moskaug,[3] N. Kojima,[1] M. Miura,[1] K. Imai,[1] M. Sato,[1] N. Roos,[4] T. Berg,[4] K. R. Norum,[3] R. Blomhoff[3]; [1]Department of Cell Biology and Histology, Akita University School of Medicine, Akita, Japan, [2]Liver Research Unit, Minophagen Pharmaceutical Co. Ltd., Tokyo, Japan, [3]Institute for Nutrition Research, University of Oslo, Faculty of Medicine, Oslo, Norway, [4]Department of Biology, University of Oslo, Oslo, Norway

After getting permission to hunt the animals from the district governor of Svalbard, 11 arctic foxes, 14 bearded seals, 22 glaucous gulls, 5 fulmars, 4 Brünnich's guillemots, 6 ringed seals, 5 hooded seals, 6 puffins, 5 Svalbard ptarmigans and 7 Svalbard reindeers were caught in the period from August 1996 to September 2001. Three polar bears were shot in self-defense at Svalbard February and August 1998 in Ny Ålesund and Hornsund. Four polar bears were caught in August 2004 in Greenland. We also obtained 13 brown bears from Jämtland, Gävleborg and Dalarna, 4 red foxes from Västergötaland, and 8 grey gulls from Skåne, Sweden. Fresh organs, namely, the liver, kidney, spleen, lung, and jejunum were examined by morphological methods such as gold chloride method, fluorescence microscopy for detection of vitamin A autofluorescence, and transmission electron microscopy, and high-performance liquid chromatography. The arctic animals stored vitamin A in hepatic stellate cells. Only a small amount of vitamin A existed within other organs such as kidney, spleen, lung, and jejunum. Top predators among arctic animals stored 6-23 micro mole retinyl ester per g liver which 20-100 times the levels normally found in other animals including humans. These results indicate that the hepatic stellate cells in these animals have high ability for uptake and enough capacity for storage of vitamin A. The liver lobules of the arctic animals showed a zonal gradient in the storage of vitamin A. The gradient was expressed as a symmetric crescendo-decrescendo profile starting at the peripheral zone in the lobule. The density of hepatic stellate cells was essentially the same among the zone. These results indicate that the heterogeneity of vitamin A-storage capacity in hepatic stellate cells in arctic animals is genetically determined.

## Wiring the Nervous System (734-736)

734

### Mechanism of Presynaptic Assembly

Y. Jin; Molecular, Cellular & Developmental Biology, Howard Hughes Medical Institute, University of California, Santa Cruz, CA

Synapses are asymmetric cellular junctions composed of presynaptic and postsynaptic specializations. At the presynaptic terminal synaptic vesicles accumulate in an ordered fashion and docked around the electron-dense active zone. To examine the molecular mechanism controlling the formation of the cytoarchitecture of presynaptic terminals, we undertake a genetic approach in the nematode *C. elegans*. Analyses of the mutants that exhibit altered synapse structures have led the identification of conserved molecules that function to define distinct spatial domains at presynaptic terminals. Further genetic interaction studies reveal multiple signal transduction pathways involving ubiquitin-mediated protein degradation and MAP kinases play crucial roles in controlling synaptic integrity.

735

### Activity-dependent Development of Cortical Connections

A. Ghosh; University of California, San Diego, La Jolla, CA

One of the most remarkable features of the nervous system is that its development is controlled by sensory experience. The effect of experience on brain development is mediated by synaptic activity, which leads to calcium entry into the postsynaptic neuron. The mechanisms by which calcium signaling leads to lasting changes in neural circuits has been extensively investigated over the past two decades, and involves both transient and sustained biochemical changes. Whereas rapid changes in synaptic circuits are mediated by post-translational modification of proteins located near the site of calcium entry, long-term changes require new gene expression. To identify transcriptional mediators of activity-dependent development, we developed a strategy called Transactivator Trap to clone calcium-activated transcription factors in neurons. Two of these factors, CREST and NeuroD2, regulate distinct aspects of activity-dependent development. We will present molecular and genetic evidence that CREST, a CBP-binding protein, plays a key role in mediating activity-dependent development of cortical dendrites, and that NeuroD2 plays a critical role in synapse maturation and the patterning of thalamo-cortical connections. These findings advance our understanding of the transcriptional mechanisms by which sensory experience regulates brain development.

736

### Effects of Experience on Visual System Development

H. Cline; Cold Spring Harbor Laboratory, Cold Spring Harbor, NY

We examined the effect of visual experience on the development of the retinotectal system in Xenopus tadpoles. Dendritic and axonal arbors of developing neurons grow by the stabilization of a small fraction of highly dynamic branches. To test the effect of synapse maturation on axon arbor development, we co-expressed cytosolic fluorescent protein and fluorescent protein tagged synaptophysin (SYP) in retinal cells to reveal presynaptic sites within labeled retinotectal axons. Two-photon time lapse observations demonstrated that synaptic contacts stabilize retracting branches. Patterned visual activity stabilized retinal axon arbor structure by reducing the extension of new branches and by increasing retractions of branches to sites stabilized by strong synapses. To test whether glutamatergic synaptic maturation affects the development of dendritic arbors, we interfered with AMPA receptor trafficking into synapses by expressing the intracellular C-terminal domains of AMPA receptor subunits GluR1 or GluR2 in individual optic tectal neurons. This reduced AMPA mEPSC amplitude by 50% and dramatically altered dendritic arbor growth over 5 days, resulting in less complex arbors. Time-lapse images show that expression of GluR C-terminal domains decreased the stability of dendritic branches, suggesting that glutamatergic synapse maturation stabilizes dendritic branches. In control GFP-expressing neurons, visual stimulation increases dendritic arbor growth by increasing branch stabilization. Expression of GluR C-terminal domains completely blocked the experience-dependent increase in dendritic arbor growth rates. These data demonstrate that visual stimulation affects retinotectal development by differentially influencing afferents and dendrites: experience consolidates axon arbor structure by restricting branch extensions and retractions, whereas experience promotes dendritic arbor growth by stabilizing newly added dendritic branches.

## The Nature of Life: An Orientation Course that Introduces Freshmen to the Disciplines of Biology, Builds Community, and Teaches Strategies for Success in College (737)

737

### The Nature of Life: An Orientation Course That Introduces Freshmen to the Disciplines of Biology, Builds Community, and Teaches Strategies for Success in College

R. Wright, J. S. Anderson, D. Biesboer, S. Cotner, S. Gilbert; College of Biological Sciences, University of Minnesota, Minneapolis, MN

The University of Minnesota aims to increase the retention and graduation rates of entering freshmen. To help accomplish this goal, the College of Biological Sciences has developed a one-credit orientation course called “The Nature of Life” that is required for all of its incoming freshmen, a class of ~350 students. The Nature of Life program introduces students to the breadth of biological disciplines, acquaints them with college and university resources, and helps them become integrated into a community of learners. The program begins with a four-day experience at the Itasca Biological Station and Laboratories located at the headwaters of the Mississippi River. During this time, students participate in three different interactive learning modules that focus on topics ranging from bioethics and neurobiology to aquatic ecosystems and spatial modeling. Additional programming includes plenary lectures and discussions about career planning, time management, research involvement, campus resources, and University of Minnesota traditions. A college-level exam is given, graded, and returned to students on the last evening of the program, followed by a discussion of strategies for more effective learning. To receive credit for the course, students must also prepare three reflective essays, attend events on campus, and participate in discussions of articles from a popular science magazine. First semester freshmen who participated in the Nature of Life program have higher overall GPAs and fewer failing grades than those of previous years. In addition, one year retention in the college increased from 66% to 81%. To our knowledge, this program is unique among research universities in the United States and provides a

model for supporting a successful transition of students from high school into the academic challenges of the university.

## Adapting to Stress: Spotlight on Organelles (738-740)

738

### A Novel Class of Membrane Proteins Shapes the Tubular Endoplasmic Reticulum

G. K. Voeltz,[1] W. A. Prinz,[2] J. M. Rist,[3] T. A. Rapoport[1]; [1]Department of Cell Biology, HHMI/Harvard Medical School, Boston, MA, [2]Laboratory of Cell Biochemisry and Biology, NIDDK/National Institutes of Health, Bethesda, MD, [3]Department of Cell Biology, Harvard Medical School, Boston, MA

How is the characteristic shape of a membrane-bound organelle achieved? We have used an in vitro system to address the mechanism by which the tubular network of the endoplasmic reticulum (ER) is generated and maintained. Based on the inhibitory effect of sulfhydryl reagents and antibodies, we demonstrate that network formation in vitro requires the integral membrane protein Rtn4a/NogoA, a member of the ubiquitous reticulon family. Both in yeast and mammalian cells, the reticulons are largely restricted to the tubular ER and excluded from the continuous sheets of the nuclear envelope and peripheral ER. Upon overexpression, the reticulons form tubular membrane structures. The reticulons interact with DP-1/Yop1p, a conserved integral membrane protein that also localizes to the tubular ER. The simultaneous absence of the reticulons and Yop1p in S. cerevisiae results in disrupted tubular ER. We propose that these proteins stabilize ER tubules by utilizing a common hairpin structure to partition into and stabilize highly curved membranes.

739

### Controlling Endoplasmic Reticulum Client Protein Load

D. Ron; Skirball Institute, New York University School of Medicine, New York, NY

In eukaryotic cells the vast majority of secreted and membrane bound proteins are synthesized in association with endoplasmic reticulum (ER) membranes. Newly-synthesized proteins, or segments thereof, are translocated into the lumen of the ER where they are acted on by an elaborate post-translational protein-handling machinery unique to that organelle. That machinery affects various post-translational modifications in ER client proteins, promotes the folding of individual client polypeptides and assembles multimeric complexes from individual subunits. It is also identifies terminally-misfolded proteins and promotes their destruction. The equilibrium between the ER's protein handling machinery and the load of client proteins is maintained by a dedicated set of signal transduction pathways collectively referred to as the Unfolded Protein Response (UPR). The UPR culminates in two major adaptations to a shift in the equilibrium favoring unfolded client proteins (a shift referred to heuristically as ER stress): (i) Activation of a transcriptional program that enhances the organelle's capacity to deal with client proteins. (ii) Attenuation of the influx of client proteins into the lumen of the endoplasmic reticulum. In this presentation we will focus on the second adaptation. We will review the molecular mechanisms underlying cell's ability to control the flux of client proteins into the ER and will discuss various examples of the consequences of failures in this "primary prevention" strategy against ER stress.

740

### An Unexpected Role of Bcl-2 Family Members in Mitochondrial Morphogenesis

R. J. Youle; Biochemistry Section, Surgical Neurology Branch, National Institute of Neurological Disorders and Stroke, NIH, Bethesda, MD

Bax, a member of the Bcl-2 family, is required for the normal program of cell death during mammalian development. Early during apoptosis, as an essential step in cell death promotion, Bax translocates from the cytosol to mitochondria almost simultaneously with a dramatic fragmentation of the normal mitochondrial network. Subsequent to translocation to the outer mitochondrial membrane, Bax coalesces into huge complexes on the surface of mitochondria at sites that subsequently constrict and become points of mitochondrial fission. The mitochondrial fission and fusion machinery is comprised of several proteins including dynamin related protein 1 (Drp1) and mitofusin 2 (Mfn2) both of which colocalize with Bax in foci at prospective mitochondria fission sites. Inhibition of mitochondrial fission inhibits apoptosis further suggesting that Bax may participate in a specialized mitochondrial fission process during apoptosis. An endophilin isoform that binds to Bax during apoptosis is normally involved in regulating mitochondrial morphology in healthy cells. Using RNA interference to deplete cells of endophilin B1 causes some dissociation of the outer mitochondrial membrane compartment from that of the matrix and the formation of thin, elongated tubules of outer mitochondrial membrane. Knock down of Drp1 in addition to knock down of endophilin B1 leads to a mitochondrial phenotype identical to that of the Drp1 single knock down, a result consistent with Drp1 acting upstream of endophilin B1 in the same pathway of mitochondrial division. Thus, mitochondrial fission requires two proteins, Drp1 and endophilin B1, homologous to two members of the synaptic vesicle recycling system pointing to an unanticipated relationship in the mechanism of these two processes. Interestingly, knock down of endophilin B1 also confers cellular resistance to a number of apoptosis pathways suggesting that it may participate with Bax in outer mitochondrial membrane remodeling during cell death.

## Cell Migration/Motility (741-746)

741

### Vesicular Trafficking And Signal Relay During Chemotaxis

P. W. Kriebel, V. A. Barr, V. A. Mihaylov, C. A. Parent; Laboratory of Cellular and Molecular Biology, National Cancer Institute/NIH, Bethesda, MD

The social amoebae *Dictyostelium*, human leukocytes, as well as many other types of cells possess the ability to polarize and move in a directed fashion in response to chemoattractants. In *Dictyostelium* the most potent chemoattractant is cAMP, which like chemokines, transduces its effects by binding to G protein-coupled receptors. The binding of cAMP to the cAMP receptor cAR1 activates a variety of effectors, including the activation of the adenylyl cyclase ACA, which converts ATP to cAMP. The majority of cAMP is then secreted to relay the chemoattractant signal to neighboring cells. Using the GFP technology, we have shown that ACA is highly enriched at the back of chemotaxing cells. We propose that this provides a compartment from which cAMP is secreted allowing cells to orient themselves and form chains of cells or streams. In addition to its localization at the plasma membrane, we find that ACA exists in an internal pool of vesicles that show rapid dynamic movement. These vesicles do

not co-localize with ER or Golgi markers. Similarly, Alexa594-dextran or Alexa594-BSA, which label the lysosomal pathway, do not co-localize with ACA. We investigated whether these vesicles are involved in the trafficking of ACA using photo-bleaching studies. We bleached a small box encompassing the plasma membrane and monitored the fluorescence recovery. While the cAR1-GFP recovery occurs first in the edges of the bleached box, we find that the ACA-YFP fluorescence recovery occurs uniformly on the plasma membrane and, most remarkably, that the extent of recovery increases and is targeted to the back of the cells as they differentiate and polarize. These results suggest that ACA is replenished via vesicles fusion to the plasma membrane. We propose that membrane trafficking is part of a regulatory mechanism that controls the activity of ACA.

742

**Posttranslational N-terminal Arginylation Regulates Cell Motility and Actin Cytoskeleton**

M. Karakozova,[1] M. Kozak,[1] R. Rai,[1] C. C. L. Wong,[2] A. O. Bailey,[2] J. R. Yates,[2] A. Kashina[1]; [1]Department of Animal Biology, University of Pennsylvania, Philadelphia, PA, [2]The Scripps Research Institute, LaJolla, CA

N-terminal arginylation is a poorly understood posttranslational modification that is critical for embryogenesis, cardiovascular development, and angiogenesis in mammals. To understand the physiological role of protein arginylation, we developed a screen to identify proteins arginylated in vivo. We found that actin and several other major components involved in cytoskeleton structure and regulation are directly regulated by arginylation. Several properties of actin, including its ability to bind actin-associated proteins, are affected by arginylation and altered in arginylation-deficient actin preparations. Analysis of the morphology and behavior of cultured embryonic fibroblasts derived from the ATE1 knockout mice indicates that arginylation regulates cell motility and adhesion by affecting cytoskeleton, focal adhesions, and extracellular matrix, and that the absence of ATE1 results in the inability of cultured cells to form a lamella and impairment of their directional migration across the substrate. These changes appear to be directly linked to the corresponding arginylation targets and suggest a new mechanism for the regulation of cytoskeleton and cell motility that can explain the observed effects of ATE1 knockout in vivo.

743

**IQGAP1-Stimulated Actin Assembly Linked to Growth Factor Receptor Activation**

L. B. Benseñor, N. Wang, H. M. Kan, S. C. Mateer, L. E. Morris, D. A. Schafer, G. S. Bloom; Department of Biology, University of Virginia, Charlottesville, VA

IQGAP1 is an actin-binding protein that concentrates at sites of branched actin filament assembly at leading edges of migratory cells. In endothelial cells, IQGAP1 binds the cytoplasmic tail of VEGFR2 after receptor activation by VEGF, and siRNA-induced reduction of IQGAP1 inhibits VEGF-stimulated cell motility (Yamaoka-Tojo, et al. 2004. Circ. Res. 95: 276-283). We now present evidence that this motility requirement for IQGAP1 reflects the ability of IQGAP1 to stimulate branched actin filament assembly, and that in non-endothelial cells, which lack VEGFR2, IQGAP1 works through at least one other receptor, FGFR1. In vitro assays with purified proteins demonstrate that IQGAP1 stimulates branched actin filament assembly comparably to activated Cdc42 in the presence of N-WASP and Arp2/3 complex, and acts additively with Cdc42 to stimulate polymerization kinetics further and reduce the lag that precedes maximal F-actin assembly rates. Actin assembly is not stimulated by IQGAP1 fragments lacking the actin-binding region or more C-terminal domains, or by full length IQGAP1 that is prevented from binding actin by calmodulin. Studies of CV-1 and MDBK cells stimulated with serum or bFGF establish in vivo relevance for these results. Serum stimulation leads to rapid recruitment of IQGAP1, N-WASP, Arp3 and FGFR1 to lamellipodia, as judged by immunofluorescence, and to time-dependent increases in levels of N-WASP, Arp3 and FGFR1 that co-IP with IQGAP1. Stimulation with bFGF similarly causes recruitment of FGFR1 and IQGAP1 to lamellipodia. These results establish IQGAP1 as a major, but previously unrecognized regulator of actin assembly and cell motility mediated by Arp2/3 complex and N-WASP, and imply that this property of IQGAP1 is coupled to growth factor receptor signaling.

744

**Intracellular Fluid Dynamics in Motile Fish Keratocytes**

K. Keren,[1] B. Hebert,[2] T. F. Harper,[3] P. W. Wiseman,[2,4] A. Mogilner,[5] J. A. Theriot[1]; [1]Dept. of Biochemistry, Stanford University, Stanford, CA, [2]Dept. of Physics, McGill University, Montreal, PQ, Canada, [3]Quantum Dot Corporation, Hayward, CA, [4]Dept. of Chemistry, McGill University, Montreal, PQ, Canada, [5]Dept. of Mathematics and Center for Genetics and Development, University of California, Davis, CA

Molecular mechanisms and biophysical processes are intimately intertwined to generate the robust large-scale self-organization manifested by a moving cell. While much research has been devoted to the molecular mechanisms underlying cell motility, less is known about its biophysical aspects such as the intracellular fluid dynamics. We are measuring the flow and effective diffusion in the fluid phase of moving cells, which are important biophysical parameters, as well as being a significant determinant for the intracellular transport of molecular components. In order to study the fluid dynamics inside living cells we introduce polyethylene glycol-coated quantum dots (QDs) as inert tracers into fish epidermal keratocytes. We follow the motion of the QDs by live-cell fluorescence microscopy, and extract their behavior by both spatio temporal image correlation spectroscopy and single particle tracking. Moving cells exhibit a directed fluid flow in the lamellipodium away from the cell's leading edge and back towards the cell body at a speed ~30% of the cell movement speed. To further understand the relationship between intracellular fluid flow and cell motility we use various perturbations which are known to alter the fluid flow through the cell membrane (e.g. Hg, 5-(N-ethyl-N-isopropyl) amiloride and osmolarity shifts) or the properties of the actin meshwork (e.g. blebbistatin) and study their effect. We find that fluid flow does not have a significant contribution to the transport of essential components of the actin machinery to the leading edge in keratocytes, and that this transport is largely maintained by random diffusive-like motion. The measured fluid flow seems to concur with theoretical predictions based on a mathematical model of keratocyte motility.

745

**A Novel Function for the Polarity Regulator Scribble in T Lymphocyte and Epithelial Cell Migration**

L. E. Dow, M. J. Ludford-Menting, J. Oliaro, F. Sacirbegovic, J. Kauffman, R. M. Iazzolino, S. M. Russell, P. O. Humbert; Research Division, Peter MacCallum Cancer Centre, Melbourne, Australia

Analyses of *Drosophila melanogaster*, zebrafish and mouse mutants have highlighted an important role for the polarity regulator Scribble in the

organization of epithelial tissue during embryonic development. In particular, mutation of Scribble in *Drosophila* epithelium gives rise to loss of apical-basal cell polarity and tissue overgrowth. As such, Scribble has classically been defined as a neoplastic tumour suppressor. We have utilized a combination of mammalian and *Drosophila* systems to identify and characterize the cellular functions of Scribble in development and cancer. Here we show a novel conserved function for Scribble in the regulation of T lymphocyte and epithelial cell migration. We show that in T lymphocytes, Scribble and associated polarity proteins polarize to the uropod of migrating T cells and disruption of the Scribble complex prevents uropod formation and inhibits migration. In mammary epithelial cells, Scribble is recruited to the leading edge of migrating cells and loss of Scribble results in impaired directed migration. Scribble-depleted epithelial cells fail to re-orient their MTOC/Golgi in response to directional migration cues and show disruption of the microtubule network and decreased Rac-1 containing actin rich protrusions at their leading edge. Importantly, Scribble physically interacts with regulators of RhoGTPases in both T lymphocytes and mammary epithelial cells. We propose a model by which Scribble coordinates directional migration through the regulation of the polarised distribution of the machinery required for cell movement.

746

**Plasticity of tumor invasion: Molecular mechanisms of mesenchymal-amoeboid transition after loss of integrin function**

P. Friedl; Cell Migration Laboratory, Department of Dermatology, University of Würzburg, Würzburg, Germany

Tumor cell migration through connective tissue requires adhesive cell matrix interactions provided by surface integrins and other adhesion systems. We have investigated, whether tumor cell migration in 3D ECM environments is fully abrogated by blocking integrin functions and whether migratory rescue may occur. Within 3D collagen matrices, invasive MV3 melanoma cells preferentially utilize α2β1 integrins for elongation, adhesion to collagen fibers, fiber bundling, force generation, and migration. Using these cells, β1 integrin function was reduced by i) flow cytometric sorting for subsets expressing low integrin levels; ii) blocking anti β1 mAb 4B4 at different concentration; iii) rhodocetin, a selective α2β1 disintegrin. Lowering β1 integrin function resulted in a varying yet incomplete reduction of migration rates accompanied by the conversion from fibroblastlike spindle-shaped morphology to more spherical amoeboid morphodynamics, and concomitantly abolished capacity to contract and remodel 3D collagen lattices. Residual amoeboid migration efficiencies amounted to undiminished 0,3- 0,4 µm/min in faster and 0,03-0,1 µm/min in slower cell subsets, sustained by propulsion and squeezing along matrix gaps provided by a strictly cortical actin cytoskeleton but lacking integrin and actin focalization at cell-matrix interactions. These findings were confirmed for fibroblast-like cells derived from β1-/- ES cells (GD25) and β1-/- murine fibroblasts, both of which exhibited slow (GD25) or fast amoeboid movement (β1-/- fibroblasts) after β1 integrin deletion. After simultaneous inhibition of ß1, αvβ3, and GAG-mediated cell-ECM interactions the residual migration was abolished in >60% of the cells and 30% exhibitng minimal residual movement below 0.02 µm/min. In conclusion, mesenchymal-amoeboid transition after abrogation of integrin function is a rescue mechanism supporting residual cell migration by low- or non- adhesive mechanisms through the surface glycocalyx.

## Chromatin Dynamics (747-752)

747

**Condensin I Stabilizes Chromosomes Mechanically Through a Dynamic Interaction in Live Cells**

D. Gerlich,[1] T. Hirota,[2] B. Koch,[2] J. M. Peters,[2] J. Ellenberg[3]; [1]Institute of Biochemistry, ETH Zuerich, Zuerich, Switzerland, [2]Research Institute of Molecular Pathology, Vienna, Austria, [3]Gene Expression and Cell Biology/Biophysics Programmes, EMBL Heidelberg, Heidelberg, Germany

Restructuring chromatin into morphologically distinct chromosomes is essential for cell division, but the molecular mechanisms underlying this process are poorly understood. Here, we investigated the function of the proposed key factors condensins, functionally tagged with GFP, in live cells. Using fluorescence photobleaching and quantitative time-lapse imaging, we found that condensin II bound stably to chromosomes throughout mitosis. By contrast, the canonical condensin I was not present on chromosomes until the completion of prophase condensation. After nuclear envelope breakdown, condensin I rapidly associated with chromosomes through a dynamic interaction, reaching steady state levels before congression. In condensin I depleted cells, compaction was normal, but chromosomes were mechanically labile and unable to withstand spindle forces during alignment. We propose that chromosome condensation is a stepwise process of compacting highly plastic chromatin in prophase, in part mediated by condensin II, followed by locking the condensed chromatin in a rigid state through rapid condensin I binding after nuclear envelope breakdown, which prepares chromosomes for subsequent spindle attachment.

748

**A Family of Site-Specific Binding Proteins Controls Meiotic Chromosome Pairing and Segregation in *C elegans***

C. M. Phillips,[1] A. Sato,[2] C. Wong,[1] A. F. Dernburg[1,3]; [1]Department of Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA, [2]Graduate School of Biostudies, University of Kyoto, Kyoto, Japan, [3]Life Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA

Physical interactions between homologous chromosomes are essential for genetic recombination and accurate segregation during meiosis. To understand the mechanisms underlying meiotic chromosome dynamics, we have focused on the roles of specific chromosome sites known as Pairing Centers, which we have shown to mediate homolog pairing and synapsis in *C. elegans*. Through genetic interactions with Pairing Center mutations, we identified a gene, *him-8*, which is specifically required for *X* chromosome segregation. We cloned *him-8* and learned that it encodes a C2H2 zinc finger protein that associates specifically with the Pairing Center of the X chromosome and also with the nuclear envelope. Identification of *him-8* also revealed that it is just one member of a multi-gene family transcribed from the same operon. Cytological analysis of the localization of the other family members has revealed that each protein is expressed during meiosis, localizes to the nuclear envelope, and binds to the Pairing Center(s) of either one or two specific autosomes. We have also observed colocalization of these proteins with patches of SUN-1 and ZYG-12, two transmembrane proteins that are thought to bridge the inner and outer nuclear envelope and to mediate centrosome attachment. These observations suggest a role for cytoskeletal components in homologous chromosome pairing and synapsis.

749

**Purification of Native Silent Chromatin in Budding Yeast**

A. D. Rudner, S. Gerber, S. Gygi, D. Moazed; Cell Biology, Harvard Medical School, Boston, MA

Silent chromatin, or heterochromatin, is found at telomeres, the *HM* loci and rDNA repeats in budding yeast. Like heterochromatin in other organisms, silent chromatin is a repressive chromatin structure that is late replicating, refractory to transcription and recombination, and is epigenetically inherited. Silent chromatin in budding yeast is thought to assemble from a complex of Sir2, Sir3 and Sir4 (the SIR complex) spreading along hypoacetylated regions of chromatin. An analogous structure exists in fission yeast and larger organisms where the Swi6 (an HP1 homologue) protein spreads along regions of chromatin that are methylated at lysine 9 of histone H3. Genetic screens have identified other proteins that are involved in initiating the assembly of silent chromatin, but no method has allowed a systematic identification of the complete set of proteins physically present in this repressive chromatin domain. In order to determine the precise structure and protein composition of silent chromatin we have developed a method of biochemically purifying fragments of native silent chromatin. As expected, these fragments contain the SIR complex, stoichiometric quantities of nucleosomes, as well as proteins that initiate silent chromatin assembly. In addition we find a large group of known chromatin proteins as well as others with unknown roles in chromosome metabolism. One co-purifying protein is the protein Asf2 that we have determined is a core component of silent chromatin and binds tightly to the SIR complex. We suspect that Asf2 may play a role in disassembling silent chromatin because overexpression of *ASF2* disrupts both silencing and the formation of the SIR complex in vivo. We are currently studying the mechanism by which Asf2 disassembles silent chromatin and the physiological processes that require such disassembly.

750

**ATP-dependent Nucleosome Remodelling Factors: Motors for Epigenetic Inheritance**

P. D. Varga-Weisz; Babraham Institute, Cambridge, United Kingdom

ATP-dependent nucleosome remodelling factors are key mediators of chromatin dynamics involved in transcription regulation, DNA- replication and repair. Our work indicates a role for these factors in determining chromatin structure right at the DNA replication fork. The nucleosome mobilizing ATPase Imitation Switch (ISWI) is an important nucleosome remodelling factor in mammalian cells. It forms several functionally and biochemically distinct remodelling factors by interacting with other proteins. One of these is the Williams-Syndrome Transcription Factor, WSTF. We observed that the ATP-dependent nucleosome remodelling complex WICH (WSTF-ISWI Chromatin remodelling factor) is targeted to replication sites via replication molecule PCNA and determines the structure of newly replicated chromatin. Depletion of WSTF results in formation of aberrant heterochromatin like structures and impairs transcription. We propose a model that postulates that the action of remodelling factors, such as WICH, is required right at the replication fork to facilitate the rebinding of factors that determine chromatin structure and transcriptional status. Thus, such factors facilitate the maintenance of chromatin structures from the parental DNA to the daughter DNA strands. Currently we are testing if other ATP-dependent nucleosome remodelling factors may function in a similar mode. In fission yeast, we do not find orthologues of ISWI, but a member of another class of ATP-dependent nucleosome remodelling factors may target the replication site there to determine chromatin structure. References: Poot RA, Bozhenok L, van den Berg DL, Steffensen S, Ferreira F, Grimaldi M, Gilbert N, Ferreira J, Varga-Weisz PD. The Williams syndrome transcription factor interacts with PCNA to target chromatin remodelling by ISWI to replication foci. Nat Cell Biol. 2004 Dec;6(12):1236-44. Poot RA, Bozhenok L, Nicola Hawkes Varga-Weisz PD. Chromatin Remodeling by WSTF-ISWI at the Replication Site: opening a Window of Opportunity for Epigenetic Inheritance? Cell Cycle, 4 (4) 543-6.

**Mechanisms of Activation and Silencing of the Immunoglobulin Kappa Locus through DNA Looping and Nuclear Repositioning to Heterochromatin**

Z. Liu, P. Widlak, Y. Zou, M. Oh, M. Chang, J. W. Shay, W. T. Garrard; Molecular Biology, UTSouthwestern Medical Center, Dallas, TX

We have investigated the higher-order chromatin structure of the mouse immunoglobulin (Ig) kappa locus as a function of activation and silencing during B cell development using the techniques of chromosome conformation capture (3C) and 3D 3-color FISH. We find that in the fully transcriptionally active state that each of the three enhancers form complexes with themselves and rearranged gene promoters, while the resulting intervening DNA is looped out. These results fit the looping model for the mechanism of enhancer action. Using chromatin immunoprecipitation in combination with 3C (e.g., ChIP-3C), we demonstrate that the transcription factor E47 is present in such looped complexes. Two of these enhancers also form complexes with a 3' boundary sequence that has CTCF sites. In addition, the 5' region of the active transcription unit exhibits a continuum of interactions with downstream chromatin segments. All of these interactions are B cell specific. Previous studies have shown that allelic exclusion of the mouse Igkappa locus occurs by the combination of monoallelic silencing and a low level of monoallelic activation for rearrangement combined with a negative feedback loop blocking additional functional rearrangements. Using yeast artificial chromosome-based single-copy isotransgenic mice, we have identified a cis-acting element that negatively regulates rearrangement in this locus, specifically in B cells. The element resides in the V-J intervening sequence, and is termed ***Sis*** (silencer in the intervening sequence). ***Sis*** specifies the targeting of germline Igkappa transgenes in B cells to centromeric heterochromatin and their association with Ikaros, a repressor protein that also co-localizes with centromeric heterochromatin. Significantly, these are hallmarks of silenced endogenous germline Igkappa genes in B cells. These results provide new insights into the molecular mechanisms of allelic exclusion.

752

**Genome Organizer SATB1 in Breast Carcinogenesis**

H. J. Han, T. Kohwi-Shigematsu; Life Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA

It is largely unknown how chromatin is packaged in eukaryotic cells so that numerous genes are properly regulated in a cell-type and stage-specific manner. Our findings on SATB1 function introduced a concept that a single protein can control numerous genes as a genome organizer. SATB1 forms a unique intranuclear architecture which provides docking sites for specialized DNA sequences, enzymes that modify chromatin structure and protein factors necessary for gene expression (1,2). Thus SATB1 determines the local chromatin structure so as to confer a specific pattern of gene expression. Until now, most studies from our group on SATB1 focused on T cell development because SATB1 is predominantly expressed in thymocytes and activated T cells. Recently, we found SATB1 is also expressed in metastatic but not in non-metastatic breast cancer cell lines, and

primarily in aggressive human breast tumor specimens. Interestingly, in metastatic breast cancer cells SATB1 specifically targets a totally different set of genes than in thymocytes. Those genes regulated by SATB1 in breast cancer cells have important roles in breast cancer development and/or progression. We will describe the biological role of SATB1 in breast cancer progression as was analyzed using RNAi techniques. Our new data show that in breast cancer cells, SATB1 acts as a key player in re-organization of the genome that switches the pattern of gene expression such that the cells acquire metastatic properties. These findings indicate that changes in higher-order packing of chromatin is crucial for progression of breast tumorigenesis. ## Coordination of Cytoskeletal Networks (753-758)

753

### Control of the Cytokinetic Rho Activity Zone by Gefs and Gaps

A. Miller, A. Clark, W. Bement; University of Wisconsin, Madison, Madison, WI

Cytokinesis is the final stage of cell division where one cell is separated into two. Classic experiments demonstrated that the spindle microtubules provide a signal that specifies the position where the actomyosin-based contractile ring should form. The nature of this signal and how it is delivered to the proper location remain mysterious, although emerging evidence implicates the small GTPase RhoA. We recently showed that a precisely-bounded, microtubule-dependent zone of high RhoA activity forms during cytokinesis in echinoderms and in Xenopus embryos. Importantly, these RhoA activity zones appear before furrowing begins and predict the location where the cleavage furrow will form. Moreover, recent work from other labs has shown that Ect2 (a RhoA GEF also known as Pbl), MgcRacGAP (a RhoA GAP also known as Cyk-4 or RacGAP50c), and MKLP (a kinesin also known as Zen-4, Pavarotti, or CHO1) are localized at the furrow and are important regulators of cytokinesis. Taken together, these results suggest that microtubules may specify the position of the contractile ring by precisely localizing regulators of RhoA activity, which then direct formation of a localized RhoA activity zone. Therefore, we are examining the roles of the RhoA regulators Ect2 and MgcRacGAP in modulating the RhoA activity zone during cytokinesis in Xenopus embryos. We find that both Ect2 and MgcRacGAP are required for cytokinetic RhoA activity zone formation, organization, and dynamics, explaining the necessity of these proteins for cytokinesis.

754

### Anillin and the Septins Increase the Efficiency of the Contractile Ring

A. S. Maddox, A. Desai, K. Oegema; Cell and Molecular Medicine, LICR / UCSD, La Jolla, CA

Constriction of the contractile ring changes the shape of the cell to facilitate cell division. We have developed live, fluorescence-based assays to analyze the roles of several structural components of the contractile ring in the *C. elegans* embryo. In addition to filamentous actin and myosin II, the septins form membrane-associated filaments that concentrate in the contractile ring. Anillin, another contractile ring component, interacts with all three cortical filament systems. Anillin is required to recruit the septins to the contractile ring, but localizes independently of myosin II and its activator, Rho-kinase. RNAi mediated depletion of myosin II completely inhibits furrow ingression. In contrast, depletion of either the septins or anillin results in only a slight late defect in the kinetics of furrow closure, but initiation and the majority of ingression are normal, and cytokinesis completes successfully. Interestingly, levels of equatorial myosin II are much higher throughout cytokinesis in anillin and septin depleted embryos than in control embryos. This observation raised the possibility that anillin and the septins decrease the amount of myosin II that is required for successful ingression. To test this idea, we utilized a sensitized condition in which the ability to activate myosin II is compromised. Rho-kinase contributes to myosin activation and recruitment in many systems. In *C. elegans*, depletion of Rho-kinase delays furrow initiation and slows ingression, but cytokinesis completes successfully. However, when anillin or the septins were depleted in conjunction with Rho-kinase, there was a synergistic defect in furrow ingression and cytokinesis failed. Two possible explanations for these results are: (1) anillin/septins increase the efficiency of the contractile machinery so that less myosin II is required, or (2) anillin/septins change the properties of the cortex, perhaps by reducing its rigidity, reducing the requirement for contractility.

755

### Drosophila Thrombospondin Promotes Muscle-specific Interaction with Tendon Cells

T. Volk, A. Subramanian; Molecular Genetics, Weizmann Institute, Rehovot, Israel

The formation of functional contractile system during embryonic development requires a perfect match between somatic muscles and their corresponding tendon cells. Migrating myotubes are guided to extend their leading edge towards tendon cells, born in the ectoderm germ layer. Once reaching the tendon cell, an EgfR-dependent signaling is triggered by the muscle, leading to elevation of the levels of the tendon-specific EGR-transcription factor Stripe. Stripe elevation induces tendon cell maturation and triggers the formation of muscle-tendon junction. By performing a microarray screen for stripe down-stream genes, we identified Drosophila Thrombospondin (Tsp). Thrombospondin is a tendon-specific extracellular matrix component. We have produced tsp mutants in which the conserved C-terminal domain of Tsp is deleted. This mutation is embryonic lethal. In embryos homozygous for tsp the somatic muscle pattern is disrupted; some muscles round up, and other muscles do not interact with tendon cells, and instead form ectopic junctions with neighboring muscles. Furthermore, the accumulation of the cytoplasmic protein Talin at the muscle-tendon junctions, which is indicative of the activation of Integrin-mediated signaling, is significantly reduced. Ectopic expression of Tsp in the entire embryonic ectoderm disrupts muscle patterning and forces the muscles to interact with non-tendon ectodermal cells. The activity, and ability to rescue the tsp mutant phenotype by expressing truncated Tsp proteins lacking either the N-terminal or C-terminal domains in tendon cells, is currently tested. These studies suggest that while guidance of the migrating muscles is performed by secreted proteins such as Slit, and possibly Netrin, Tsp function is necessary to signal the approaching muscle to specifically interact with the tendon cell, rather than with neighboring muscles. Thus, Tsp activity in Drosophila is reminiscent of the recently reported synapse-promoting activity of this gene product in the CNS.

756

### Abelson Kinase Coordinates Apical Constriction and Rhogef2 Localization During Drosophila Morphogenesis

D. T. Fox, S. L. Rogers, M. Peifer; Biology, University of North Carolina, Chapel Hill, NC

During animal development, coordinated changes in cell shape and position mold the body plan. As the actin cytoskeleton provides the structural basis for this morphogenesis, it is crucial to identify the function of actin regulatory proteins, as well as their interplay with one another. The *Drosophila* non-receptor tyrosine kinase Abl regulates actin structure in both epithelial cells and CNS axons by antagonizing Ena, the single fly Ena/VASP family member. To understand Abl's role during epithelial morphogenesis, we generated embryos lacking maternal and zygotic Abl. We find *abl* mutant embryos have specific defects in cell shape change during gastrulation. During wild-type gastrulation, cells of the presumptive mesoderm undergo a coordinated apical constriction, which leads to their internalization in a structure known as the ventral furrow. Using both live and fixed confocal imaging, we find that in *abl* mutants the presumptive mesodermal cells fail to constrict in a coordinated manner. As a result, their internalization is asynchronous, leading to aberrant ventral furrow. Consistent with a role in coordinating apical cell shape change, we find that Abl::GFP accumulates apically in constricting cells of the ventral furrow. Further, genetic interaction analysis suggests that Abl's role in this process includes negative regulation of Ena. As previous work in both fly embryos and S2 cells has established a role for the Rho activator RhoGEF2 and Myosin in the regulation of cell constriction, we examined their localization in *abl* mutants. We find that loss of Abl disrupts RhoGEF2 localization prior to apical constriction, but not Myosin localization. This observation has led us to use both fly genetics and an S2 cell model of cell constriction to test how Abl/Ena act in parallel or in concert with previously identified RhoGEF2 regulators to coordinate apical morphogenesis in *Drosophila*.

757

### Bipolar Spindle Assembly on Linear Chromatin Structures

J. Gaetz,[1] Z. Gueroui,[2] A. Libchaber,[2] T. M. Kapoor[1]; [1]Chemistry and Cell Biology, The Rockefeller University, New York, NY, [2]Experimental Condensed Matter Physics, The Rockefeller University, New York, NY

In recent years, much experimental evidence has demonstrated that positive signals generated by chromatin can assemble mitotic spindles in the absence of centrosomes. These signals contribute to the nucleation, stabilization and organization of microtubules and may determine the shape and size of the mitotic spindle. How the spatial distribution of the chromosomal signals influences cytoskeletal organization has not been directly tested. We have developed an experimental system that can be used to control the shape of chromatin, and therefore the positive signal, during spindle assembly. In cell-free extracts prepared from *Xenopus* oocytes, DNA-coated paramagnetic beads were patterned, using electromagnetic fields, into linear structures ranging from 6 to 100 μm in length and constant width. After packaging of DNA into chromatin in the extract, these chromatin bead "strings" were capable of generating sufficient positive signal to induce spindle assembly. Here we present new data examining, in detail, the effect of altered chromatin signaling patterns on the assembly of the bipolar spindle. Experiments using chemical and protein-based inhibitors of spindle pole organization have uncovered opposing roles for signals from chromatin and spindle poles in regulating the proper size and shape of the bipolar spindle. The roles of cytoskeletal motor proteins and non-motor microtubule-associated proteins are examined. Our findings have implications for mechanisms of regulation of the cell division apparatus, as well as other dynamic intracellular structures.

758

### Two Spiral Structures Control Cell Shape in *Caulobacter crescentus*

N. A. Dye,[1] J. A. Theriot,[1] L. Shapiro,[2] Z. Gitai[3]; [1]Biochemistry, Stanford University, Stanford, CA, [2]Developmental Biology, Stanford University, Stanford, CA, [3]Molecular Biology, Princeton University, Princeton, NJ

Mutations in the bacterial actin homolog, *mreB*, confer a spherical morphology to the normally rod-shaped bacteria *E.coli*, *B.subtilis*, and *C.crescentus*. To learn more about the mechanism by which the actin cytoskeleton contributes to shape determination in bacteria, we took a cell biological approach to study two genes coexpressed with *mreB* in *Caulobacter crescentus*. *mreC* lies immediately downstream of *mreB*. When mRFP1 was fused to the putative periplasmic C-terminus of MreC, we observed a punctate, helical pattern. Upon labeling both MreB and MreC in the same strain we found, amazingly, that these two helices do not overlap. A deletion of *mreC* could not be obtained, indicating that the gene is essential in *Caulobacter*. When MreC was depleted, *Caulobacter* became lemon-shaped, mimicking the MreB depletion phenotype. MreB, however, was still able to form dynamic structures in MreC-depleted cells, indicating that MreC is not required to localize MreB. Interestingly, MreC did not require MreB for proper localization: in the presence of the MreB-inhibitor, A22, MreC still formed spirals. The gene *pbp2*, encoding a peptidoglycan transpeptidase, is also found in the *mre* operon in *Caulobacter*. When fused to GFP, Pbp2 was localized in a helical pattern overlapping with the MreC but not MreB spirals. Surprisingly, perturbing either MreB (with A22) or MreC (with depletion) caused GFP-Pbp2 to mislocalize to a midcell position, potentially providing a molecular explanation for the shape defects observed after depletion for either MreB or MreC. Depletion of FtsZ prevents this mislocalization of GFP-Pbp2 and partially rescues the cell shape defect in A22. Together our results demonstrate the existence of two separate and independent protein spirals in *Caulobacter*. These spirals, one cytoplasmic and one periplasmic, have opposing roles in regulating the localization of a transpeptidase and consequently cell shape.

## Nuclear Compartments (759-764)

759

### Analysis of Dynamic Changes in the Nucleolar Proteome and PP1 Complexes using Time-Lapse Proteomics and Time-Lapse Fluorescence Microscopy

A. I. Lamond,[1] Y. W. Lam,[1] L. Trinkle-Mulcahy,[1] J. Andersen,[2] M. Mann[2]; [1]Gene Regulation & Expression, University of Dundee, Dundee, United Kingdom, [2]Biochemistry & Molecular Biology, University of Southern Denmark, Odense, Denmark

The cell nucleus is a highly compartmentalized organelle and many nuclear proteins, including splicing factors, are organized into distinct classes of nuclear bodies, such as nucleoli, PML bodies, Cajal bodies, speckles and paraspeckles. We are studying the functional organization of mammalian cell nuclei with the aim of understanding how specific nuclear compartments are assembled and how individual protein and RNA-protein complexes are targeted to these compartments and are able to move between them (see www.LamondLab.com). We are using a

combination of quantitative proteomic methods, involving metabolic labeling of proteins with amino acids containing heavy isotopes $^{13}C$ and $^{15}N$, and quantitative in vivo imaging techniques. Experiments using multiplexed heavy isotope labeling (SILAC) and quantitative mass spectrometry have identified changes in the protein composition of the nucleolus under different metabolic conditions. Parallel studies using quantitative digital fluorescence microscopy confirm the dynamic behaviour of nucleolar proteins. A detailed description of the nucleolar proteome and the SILAC data is available in a searchable online database (see http://lamondlab.com/nopdb/). We have also used the SILAC approach in combination with time-lapse fluorescence imaging to characterize the specific interactions of targeting proteins with isoforms of protein phosphatase 1 (PP1). We have identified a novel PP1 binding factor, termed 'RePO-Man', that selectively targets a pool of PP1gamma to chromatin during mitosis at the metaphase-anaphase transition. This work offers a general approach for characterizing dynamic changes in the composition of either organelles or multi-protein complexes.

760

**Drosophila Cajal Body Components**

J. Liu,[1] C. Murphy,[1] M. Buszczak,[1] S. Clatterbuck,[2] R. Goodman,[2] J. Gall[1]; [1]Department of Embryology, Carnegie Institution of Washington, Baltimore, MD, [2]Department of Biology, Johns Hopkins University, Baltimore, MD

Cajal bodies (CBs) are intranuclear organelles that contain many components involved in transcription and processing of cellular RNA. Identification of CBs relies heavily on specific marker proteins and small RNAs, especially the protein p80-coilin. Because coilin has not been identified in *Drosophila*, we examined the U7 snRNP, which is limited almost exclusively to CBs in *Xenopus* oocytes and HeLa cells. The sequences of *Drosophila* U7 snRNA and two proteins specific for the U7 snRNP, Lsm10 and Lsm11, have been described. We produced transgenic lines of *Drosophila* that express Lsm11-GFP. We examined early embryonic blastoderm, third instar larval brains and salivary glands, and adult ovaries. The great majority of cells exhibit a single bright focus of Lsm11-GFP in their nuclei, except for nurse cell nuclei, which have multiple foci. Fluorescent in situ hybridization (FISH) demonstrated the presence of U7 snRNA in all these foci. Furthermore, FISH of a histone H4 probe showed that histone genes are colocalized with Lsm11-GFP and U7 snRNA. In *Xenopus* oocytes and HeLa cells some CBs are usually attached to the chromosomes at the histone gene loci; in *Drosophila* the association appears to be invariant. We examined two other typical CB components, U2 snRNA and U85 scaRNA. U85 was concentrated in a focus distinct from the U7 focus. Some of the U2 colocalized with the U85 focus and the rest was more diffusely spread throughout the nucleus. We will examine additional CB components in *Drosophila* to determine how their overall distribution compares with that in mammalian and *Xenopus* nuclei. In a mouse strain deficient for coilin, CB components that are typically contained in a single body are distributed into three separate nuclear bodies. An interesting possibility is that the lack of coilin in *Drosophila* results in a similar redistribution of CB components.

761

**Neuromuscular Development and snRNPs: A Fly Model for Spinal Muscular Atrophy**

T. K. Rajendra, G. Gonsalvez, H. K. Salz, G. A. Matera; Genetics, Case Western Reserve University, Cleveland, OH

Small nuclear ribonucleoproteins (snRNPs) of the Sm-class are essential pre-mRNA splicing factors. In metazoans, pre-snRNA transcripts are exported to the cytoplasm by the export adaptor, PHAX. Cytoplasmic assembly into stable Sm-core particles is mediated by the survival motor neurons (SMN) protein complex. Following additional cytoplasmic remodeling steps, the RNPs are imported into the nucleus, where they undergo further maturation and ultimately assemble into spliceosomes. Thus, the biogenesis of Sm snRNPs is a multi-step process that takes place in distinct subcellular compartments. Mutations in the human *SMN1* gene result in the neurogenetic disease, Spinal Muscular Atrophy (SMA). Although *SMN* mutations are associated with defects in formation of Sm-core RNPs *in vitro*, the link to the etiology of SMA *in vivo* is unclear. To address this question, we have developed a model system in *Drosophila* to study snRNP biogenesis. Hypomorphic mutations in the fruitfly *smn* and *smd2* genes and complete loss-of-function alleles of *phax* display an interesting phenotype that resembles SMA in several details. Both genes are essential for organismal viability and fertility, however, a fraction of the expected homozygous mutants escape the embryonic and larval lethality and survive to adulthood. These 'escapers' are sterile and unable to jump or fly, with defects in flight muscle myofibril organization. Homozygous *phax* mutants show an observable decrease in the levels of U1 and U2 snRNAs, but not in U3 or U6 RNAs. Collectively, these findings indicate a critical role for snRNPs during neuromuscular development and provide a strong connection between snRNP biogenesis and the molecular etiology of SMA.

762

**Splicing Independent Recruitment of snRNPs to Active Transcriptional Units**

S. B. Patel,[1] M. Bellini[2]; [1]Biochemistry and College of Medicine, University of Illinois at Urbana-Champaign, urbana, IL, [2]Cell & Developmental Biology, University of Illinois at Urbana-Champaign, urbana, IL

Work over the past decade has shown that the splicing of pre-mRNAs begins co-transcriptionally. However, the mechanisms that regulate the association of the spliceosomal small nuclear ribonucleoprotein particles (snRNPs) to transcriptional units remain elusive. In amphibian oocytes, RNA polymerase II transcription sites correspond to the extended lateral loops of the lampbrush chromosomes (LBCs), which are readily observable by light microscopy. Here, we show for the first time that injected fluorescently-labeled U1, U2, and U5 (a representative member of the U4/U6.U5 tri-snRNP) snRNAs do target the chromosomal loops in addition to their previously reported association with other nuclear compartments. As we were able to detect synthetic snRNAs on the LBC loops, we were curious to see whether a mutant form of U1 snRNA (ΔU1) that lacks the region required for 5'-splice site (5'-SS) recognition, and hence cannot participate in splicing, is still targeted to chromosomal loops. Surprisingly, we observed an association of ΔU1 with chromosomal loops, indicating that 5'-SS recognition is not necessary for recruiting U1 to transcription sites. This result prompted us to ask whether the snRNPs would still localize to LBC loops in absence of U2, which was previously shown to be essential for the loading of U1 and U5 onto pre-mRNA. Interestingly, in oocytes depleted of U2 snRNAs, and thus deficient in splicing, we observed that the chromosomal targeting of U1 and U5 was not affected. Taken together, these data indicate that the recruitment of snRNPs to active transcriptional units does not depend on splicing and support a two-step "recruitment-loading" model. In this model, snRNPs are first recruited to transcription sites and then loaded onto their pre-mRNA substrate.

763

**Live Cell Dynamics of PNC Components**

K. Kopp, S. Huang; Cell and Molecular Biology, Northwestern University, Chicago, IL

The perinucleolar compartment (PNC) is a sub-nuclear structure that notably localizes to the periphery of the nucleolus. The PNC is found predominantly in transformed cells both *in vitro* and *in vivo*. PNCs are highly enriched with newly synthesized RNA polymerase III transcripts and RNA binding proteins. The structural integrity of the PNC is dependent upon the transcription of these RNAs and a critical level of the polypyrimidine tract binding protein (PTB), as assayed by the localization of other PNC associated proteins. These and other observations suggest a model in which the PNC is a dynamic, functional organelle that forms under specific physiological conditions favoring cellular transformation and might be involved in the metabolism of RNA polymerase III transcripts. In order to further understand the functional role of the PNC in the metabolism of the small RNAs accumulated within, we have made an array of fusion proteins between photo-activatable GFP and a group of RNA binding proteins known to be concentrated in the PNC. Using live cell imaging, we have been able to trace the movement of proteins after leaving the PNC. Additional results will be presented.

764

**Regulation of Ubiquitin Ligase Dynamics by the Nucleolus**

K. Mekhail,[1] M. Khacho,[1] A. Carrigan,[2] R. Hache,[2] L. Gunaratnam,[1] S. Lee[1]; [1]Cellular and Molecular Medicine, University of Ottawa, Ottawa, ON, Canada, [2]Ottawa Health Research Institute, University of Ottawa, Ottawa, ON, Canada

Cellular pathways relay information through dynamic protein interactions. We have assessed the kinetic properties of the MDM2 and VHL ubiquitin ligases in living cells under physiological conditions that alter the stability of their respective p53 and HIF substrates. Photobleaching experiments reveal that MDM2 and VHL are highly mobile proteins in settings where their substrates are efficiently degraded. The nucleolar architecture converts MDM2 and VHL to a static state in response to regulatory cues that are associated with substrate stability. Following signal termination, the nucleolus is able to rapidly release these proteins from static detention, thereby restoring their high mobility profiles. A protein surface region of VHL's β-sheet domain was identified as a discrete [H+]-responsive nucleolar detention signal ($NoDS^{H+}$) that targets the VHL/Cullin-2 ubiquitin ligase complex to nucleoli in response to physiological fluctuations in environmental pH. Data shown here provide the first evidence that cells have evolved a mechanism to regulate molecular networks by reversibly switching proteins between a mobile and static state.

## Pathogens Co-opting Host Cell Functions (765-770)

765

**Clustering of $EspF_U$ Beneath the Plasma Membrane of Mammalian Cells is Sufficient to Trigger Localized Actin Assembly**

K. G. Campellone, D. Robbins, J. M. Leong; Molecular Genetics and Microbiology, UMass Medical School, Worcester, MA

Enterohemorrhagic *E. coli* (EHEC) are extracellular pathogens that utilize a specialized translocation system to deliver effector proteins into mammalian cells and reorganize the cytoskeleton into actin-rich pedestals. One effector that is essential for actin pedestal formation is Tir, a protein that inserts into the mammalian plasma membrane and acts as a receptor for the bacterial surface adhesin, intimin. EHEC additionally translocates $EspF_U$ (also known as TccP), a second critical effector of actin polymerization that mediates recruitment of the actin assembly machinery to Tir. The crucial signaling function of $EspF_U$ resides in its proline-rich domain, which contains 6 nearly-identical 47-residue peptide repeats. This region of $EspF_U$ can bind to N-WASP, a key activator of the Arp2/3 actin-nucleating complex. To define the minimal signaling requirements for actin pedestal formation by EHEC, Tir and $EspF_U$ were expressed directly in mammalian cells. Clustering of a membrane-targeted Tir derivative in the presence of $EspF_U$ was sufficient to trigger localized actin assembly, indicating that $EspF_U$ and Tir are the only two EHEC effectors necessary for pedestal formation. While a 12-residue C-terminal peptide was revealed to be the only cytoplasmic sequence of Tir necessary for signaling, a single 47-residue $EspF_U$ repeat was determined to be sufficient for interacting with N-WASP and stimulating localized actin assembly, although two repeats promoted pedestal formation more efficiently. The C-terminus of Tir serves merely to cluster $EspF_U$, because a Tir derivative in which this domain was replaced with the proline-rich region of $EspF_U$ was still functional for pedestal formation. EHEC-mediated actin assembly is more complicated than simple recruitment of N-WASP, however, because $EspF_U$ appears to interact with multiple regulators of actin polymerization.

766

**Dynamics of Polyomavirus Binding, Endocytosis and Intracellular Trafficking**

A. E. Smith,[1] H. Ewers,[1] J. Kartenbeck,[2] H. Lilie,[3] A. Helenius[1]; [1]Institute of Biochemistry, Swiss Federal Institute of Technology, Zurich, Switzerland, [2]Deutsches Krebsforschungszentrum, Heidelberg, Germany, [3]Martin-Luther-University, Halle, Germany

For productive cell entry and infection, animal viruses make use of a variety of alternative endocytic pathways. We have followed viruses as they attach to the surface of cells, move laterally along the plasma membrane, enter via endocytic vesicles and traffic in the cytoplasm. Our analysis of polyomavirus entry and infection revealed a novel, poorly characterized pathway for cellular endoyctosis and intracellular trafficking. It is initiated by high-affinity, stable membrane attachment requiring ganglioside receptors. Upon binding, individual Py virus-like particles (VLPs) generally exihibited rapid random motion, followed by actin filament-dependent confinement, as revealed by single fluorescent particle tracking performed on cells or planer supported lipid bilayers. Real-time fluorescence microscopy in combination with thin section electron microscopy, biochemical and biophysical assays revealed that for endocytosis, tyrosine kinase activity was induced, and an uncoated, cholesterol dependent, primary endocytic vesicle was formed. Virus entry was rapid, and an Arf6-, dynamin 2-, and actin-independent process. The virus-marked, pH-neutral, intracellular vesicle was initially independent of markers for classical endosomal pathway (Rab GTPases, fluid phase, transferrin, Semliki Forest virus), or of caveolin-1, and later merged with intracellular caveosomes. Overall, viruses are proving valuable tools to address the complexities of endocytic membrane trafficking and lipid domain organization.

767

**Listeria Hijacks the Clathrin-dependent Endocytic Machinery to Invade Mammalian Cells**

E. Veiga, P. Cossart; UIBC, Institut Pasteur, Paris, France

The bacterial pathogen Listeria monocytogenes uses the surface protein InlB to invade a variety of cell types. The interaction of InlB with the hepatocyte growth factor receptor, Met, is critical for infection. Here we show that purified InlB induces the Cbl-dependent mono-ubiquitination and endocytosis of Met. We then demonstrate that the bacterium exploits the clathrin-dependent endocytosis machinery to invade mammalian cells. First, we show that Listeria colocalizes with Met, EEA1, the ubiquitin ligase Cbl, clathrin and dynamin during entry. Then we dissect the role played by different proteins of the endocytic machinery during Listeria infection. Over-expression or down-regulation of Cbl respectively increases or decreases bacterial invasion. Furthermore, RNAi-mediated knock-down of major components of the endocytic machinery e.g. clathrin, dynamin, eps15, Grb2, CIN85, CD2AP, cortactin and Hrs, inhibit bacterial entry, establishing for the first time that the endocytic machinery is critical for the bacterial internalization process.

768

**Mechanisms of Sequestration of Host Lysosomes in the Unique Intracellular Vacuole Containing *Toxoplasma***

I. Coppens,[1] M. Pypaert,[2] K. A. Joiner[3]; [1]Molecular Microbiology and Immunolgy, Johns Hopkins School of Public Health, Baltimore, MD, [2]Cell Biology, Yale University, New Haven, CT, [3]Internal Medicine, Yale University, New Haven, CT

*Toxoplasma gondii* is adapted to thrive in a unique self-made niche, i.e. the parasitophorous vacuole (PV) within the cytoplasm of a large variety of mammalian cells. The PV of *Toxoplasma* is a nonfusogenic compartment, which segregates the parasites from the host cell vesicular transport system. We identified a novel strategy for nutrient acquisition by intravacuolar *Toxoplasma*. The PV accumulates material coming from the host cell via the exploitation of the host endo-lysosomal system. Videofluorescence and electron microscopic studies reveal that *T. gondii* actively recruits host microtubules around the PV, resulting in selective attraction of endo-lysosomes to the PV membrane. Interference with the function of host microtubules or lysosomes abolishes the association of PV-endocytic structures. Polymerization of host microtubules causes microtubule-based invaginations of the PV membrane. These tubular extensions serve as conduits for the delivery of host endo-lysosomes within the PV. Such conduits are decorated by transverse coated striations on their surface, reminiscent of the collars induced by dynamin. Indeed, the coat acts like a garrote that sequesters host endocytic organelles within the vacuolar space. Among parasite proteins secreted in the PV, GRA7 has the property to bind lipids, constrict spherical liposomes into branched tubules and form homo-oligomers in a liposome-stimulated manner via C-terminal hydrophobic residues. This leads to the assumption that GRA7 may constitute one major molecule forming the electron-dense coat constricting the tubular extensions of the PVM. In conclusion, these data define a new process allowing the *T. gondii* intimate and concentrated access to a diverse range of low molecular weight components produced by the endo-lysosomal system. More generally, they identify a new mechanism for unidirectional transport and sequestration of host organelles.

769

**Vaccinia Virus induced Cell Motility Involves Inhibition of RhoA Signalling**

F. Valderrama,[1] J. Cordeiro,[1] S. Schleich,[1] F. Frischknecht,[2] M. Way[1]; [1]Cell Motility Group, Cancer Research UK, London Research Institute, London, United Kingdom, [2]Department of Parasitology, Heidelberg University School of Medicine, Heidelberg, Germany

The spatial and temporal regulation of cell adhesion and motility is essential during development and throughout the lifetime of multi-cellular organisms. Deregulation of these two fundamental cellular processes frequently occurs during pathological situations and is an important factor contributing to tumour cell metastasis. Dramatic changes in cell migration and adhesion, as well as loss of contact inhibition, are also observed during viral infections including that of vaccinia virus. Using a combination of genetic and biochemical approaches we have identified a viral protein that is critically required for vaccinia-induced cell motility. This vaccinia protein, which is conserved in the genomes of orthopox viruses, binds directly to RhoA to inhibit interactions with its downstream effectors, ROCK and mDia1. Molecular ablation of this viral protein using siRNA techniques results in a loss of vaccinia-induced cell motility as well as dramatic inhibition of viral morphogenesis. Based on our observations, we suggest that modulation of RhoA signaling during the vaccinia life cycle is critically required for the continued spread of infection.

770

**Infectious Contact- Retroviral Transmission via Filopodia**

N. M. Sherer, M. J. Lehmann, P. D. Uchil, W. Mothes; Section of Microbial Pathogenesis, Yale University, New Haven, CT

During infection, enveloped viruses engage their cellular receptors and then move laterally along filopodia towards the cell body where they undergo entry (Lehmann et al, 2005. J Cell Bio 170:317-25). This transport is driven by the underlying retrograde F-actin flow and is dependent on myosin II. Like classical ligands such as EGF, viruses are transported along the cell surface to reach endocytic hot spots at the cell body prior to envelope fusion or endocytosis. Here, we show using live cell imaging that during virus assembly, in striking contrast to entry, retroviruses such as murine leukemia virus (MLV) can assemble and bud from the tips of filopodia, demonstrating that the peripheral actin cytoskeleton of infected cells supports virus movement in the opposite direction, away from the cell. Thus, infected cells apparently present retroviruses at the tips of their outermost protrusions. Co-culture experiments revealed viruses passed on from the protrusions of infected cells to filopodia of uninfected cells where they engaged rapid retrograde flow towards the cell body. These experiments demonstrate virus transmission via short contacts between filopodia rather then tight cell-cell interactions establishing an "infectious synapse" (McDonald et al, 2003. Science 300:1295-7). We predict that the contrasting tendencies of MLV trafficking seen for producer vs. target cell reflects the relative affinities of the ligand-receptor interactions involved. As such, viruses are again shown to be exploiting general pathways of cell signaling and intercellular communication.

## Regulating Intercellular Junctions (771-776)

771

**Cooperative Roles of Integrin and Nectin in the Formation of Cadherin-based Adherens Junctions**

H. Ogita, Y. Sakamoto, T. Hirota, Y. Takai; Molecular Biology & Biochemistry, Osaka University, Osaka, Japan

Cell-matrix adhesion molecule integrin has been implicated in the formation and maintenance of cell-cell junctions. Immunoglobulin-like cell-cell adhesion molecule (CAM) nectin homophilically or heterophilically *trans*-interacts with each other in a $Ca^{2+}$-independent manner to form cell-cell

contacts, where $Ca^{2+}$-dependent CAM cadherin is recruited, eventually causing formation of adherens junctions (AJs). In addition, the *trans*-interaction of nectin induces activation of Cdc42 and Rac small G proteins through c-Src and forms filopodia and lamellipodia, respectively, facilitating the formation of AJs. However, the mechanism by which integrin is involved in the formation of AJs remains to be elucidated. We examined here the physical and functional relationship between integrin $\alpha_v\beta_3$ and nectin in the formation of AJs in NIH3T3 cells. Integrin $\alpha_v\beta_3$ co-localized and associated with nectin at the nectin-based cell-cell contact sites. Furthermore, integrin $\alpha_v\beta_3$ associated with nectin at the earlier stage of the formation of AJs had the extended conformation determined by WOW-1 Fab. Then, after the establishment of AJs, the extended conformation of integrin $\alpha_v\beta_3$ diminished at AJs, although the signal for integrin $\alpha_v\beta_3$ determined by LM609 mAb was observed there together with that for N-cadherin, suggesting that the bent conformation of integrin $\alpha_v\beta_3$ exists at established AJs. On the other hand, the nectin-induced, c-Src-mediated activation of Cdc42 and Rac required the activation of integrin $\alpha_v\beta_3$. Focal adhesion kinase, which relays the integrin-mediated outside-in signals to the intracellular signaling molecules, was also necessary for the nectin-induced signaling and was involved in the association of integrin $\alpha_v\beta_3$ with nectin. Thus, integrin $\alpha_v\beta_3$ and nectin play cooperative roles in the formation of cadherin-based AJs.

**Non-static Linkage between Cadherin Complex and Actin Cytoskeleton**

S. Yamada, W. J. Nelson; Molecular and Cellular Physiology, Stanford University School of Medicine, Stanford, CA

Cell-cell adhesion is thought to be initiated through *trans* interactions between cadherin extracellular domains, and strengthened by linkage of cadherins to the actin cytoskeleton. However, we reported that α-catenin does not bind simultaneously to both E-cadherin/β-catenin and actin filaments. Upon initial cell-cell adhesion, the circumferential actin network near the initial contact site is disrupted, and lamellipodial activity, which is driven by Arp2/3 and initially active at cell-cell contacts, is dampened around maturing contacts. Arp2/3-mediated lamellipodia activity becomes restricted to the edges of cell-cell contact expansion where the circumferential actin cable terminates. Furthermore, paxillin, a focal adhesion protein, also co-localizes at this molecular complex suggesting a role of integrin adhesion in actin organization at this site. In vitro, α-catenin can suppress actin polymerization induced by the Arp2/3 complex, thus α-catenin may play an essential role in the actin reorganization during the initial stage of cell-cell adhesion. We will discuss implications of non-static linkage between cadherin-catenin complex and actin filaments during these stages of cell-cell contact formation.

773

**Preserving Junctions: Myosin 2 is a Key Rho kinase Target Necessary for the Local Concentration of E-cadherin at Cell-cell Contacts**

A. M. Shewan,[1] M. Maddugoda,[1] A. Kraemer,[1] S. J. Stehbens,[1] S. Verma,[1] E. M. Kovacs,[2] A. S. Yap[1]; [1]University of Queensland, Institute for Molecular Bioscience, Brisbane, Australia, [2]University of Queensland, School for Biomedical Science, Brisbane, Australia

Classical cadherin adhesion molecules are key determinants of tissue morphogenesis. Cadherins accumulate at cell-cell contacts as a characteristic response to homophilic ligation and this is necessary for junction assembly and tissue cohesion. The ability of cells to concentrate cadherins at contacts is a surprisingly complex process: it requires productive binding of the ectodomain to cooperate with cytoplasmic determinants, many of which remain poorly characterised. We recently identified Myosin 2 as one such cytoplasmic factor that determines whether E-cadherin can concentrate at adhesive contacts. Myosin 2 accumulated at cell-cell contacts in a cadherin-dependent manner; indeed adhesion to recombinant cadherin ligands was sufficient both to recruit and to activate Myosin 2. Inhibition of Myosin 2 activity, either directly using blebbistatin or by inhibiting MLCK, significantly reduced cadherin accumulation at cell-cell contacts measured both by quantitative immunofluorescence microscopy and by FRAP. However, total and surface levels of E-cadherin were not altered, indicating that Myosin 2 critically controlled the ability of surface E-cadherin to concentrate regionally in cell-cell contacts. The impact of Myosin 2 inhibitors on cadherin accumulation was precisely mimicked by Y27632, an inhibitor of Rho kinase. Moreover, Rho kinase signaling was necessary for cadherin adhesion to recruit and activate Myosin 2. We conclude that Myosin 2 is a key effector of Rho kinase signalling that critically regulates the ability of cadherin to concentrate at contacts in response to homophilic ligation.

**P120-Catenin Regulates Clathrin-Dependent Endocytosis of VE-cadherin**

K. Xiao,[1] J. Garner,[1] K. M. Buckley,[2] P. A. Vincent,[3] C. M. Chiasson,[2] E. Dejana,[4] V. Faundez,[5] A. P. Kowalczyk[1]; [1]Dermatology, Emory University, Atlanta, GA, [2]Graduate Program in Biochemistry, Cell, and Developmental Biology, Emory University, Atlanta, GA, [3]The Center for Cardiovascular Science, Albany Medical College, Albany, NY, [4]FIRC Institute of Molecular Oncology and Department of Biomolecular and Biotechnological Sciences, University of Milan, Milan, Italy, [5]Cell Biology, Emory University, Atlanta, GA

VE-cadherin is an adhesion molecule critical to vascular barrier function and angiogenesis. VE-cadherin expression levels are regulated by p120 catenin, which prevents lysosomal degradation of cadherins by unknown mechanisms. To test whether the VE-cadherin cytoplasmic domain mediates endocytosis, and to elucidate the nature of the endocytic machinery involved, the VE-cadherin tail was fused to the IL-2 receptor extracellular domain (IL-2R). Internalization assays demonstrated that the VE-cadherin tail dramatically increased endocytosis of the IL-2R in a clathrin-dependent manner. Interestingly, p120 inhibited VE-cadherin endocytosis via a mechanism that required direct interactions between p120 and the VE-cadherin cytoplasmic tail. However, p120 did not inhibit transferrin internalization, demonstrating that p120 selectively regulates cadherin internalization rather than globally inhibiting clathrin-dependent endocytosis. Finally, cell surface labeling experiments in cells expressing GFP tagged p120 indicated that the VE-cadherin-p120 complex dissociates upon internalization. These results support a model in which the VE-cadherin tail mediates interactions with clathrin-dependent endocytic machinery, and that this endocytic processing is inhibited by p120 binding to the cadherin tail. These findings suggest a novel mechanism by which a cytoplasmic binding partner for a transmembrane receptor can serve as a selective plasma membrane retention signal, thereby modulating the availability of the protein for endo-lysosomal processing.

**Consequences of p120ctn Ablation in the Mouse Colon and Similarities to Human Inflammatory Bowel Disease**

W. G. Smalley,[1] P. E. Burnett,[2] M. A. Davis,[1] A. B. Reynolds[1]; [1]Cancer Biology, Vanderbilt University, Nashville, TN, [2]Division of Dermatology, Vanderbilt University, Nashville, TN

siRNA-mediated p120ctn (p120) ablation *in vitro* indicates that p120 regulates E-cadherin stability and cell-cell adhesion. To examine the effects of p120 ablation in an animal model, we have generated a conditional p120 knockout mouse using Cre-loxP technology. p120 ablation was targeted to the small intestine and colon by crossing our p120 floxed mice with Villin-Cre transgenic animals from Deborah Gumucio. Immunofluorescence staining of tissue sections reveal mosaic p120 knockout in approximately half of epithelial cells from the stomach to the anus, with no other tissues affected. p120 negative regions display significant E-cadherin downregulation and striking defects in epithelial morphology and adhesion. Damage and premature enterocyte shedding cause bleeding, diarrhea, dehydration, and failure to thrive. Death occurs between 11 and 23 days after birth due to excessive bleeding into the lumen and extraordinary drop in blood hematocrit. At the cell and tissue level, we observe striking mucosal hyperplasia in the colon and over 2 fold increases in proliferation rates for both intestinal and colonic epithelium. Interestingly, there is striking recruitment of neutrophils (but not macrophages) to p120 negative regions of the colon but not small intestine suggesting an early inflammatory response. p120 downregulation has been reported in human inflammatory bowel (IBD) diseases including Crohn's disease (75% of cases) and ulcerative colitis (100% of cases), the latter being a significant precondition for colon cancer. Preliminary comparisons of p120 downregulation in human IBD tissue to p120 ablation in the mouse colon reveal striking similarities at several levels, suggesting that p120 downregulation could be causally associated with this condition in humans.

### Microtubules Target Sites of Cell-Cell Contact and May Regulate Adhesion Dynamics

L. A. Ligon, E. L. F. Holzbaur; Physiology, University of Pennsylvania, Philadelphia, PA

The regulation of intercellular junction formation and stabilization is critical to maintain the balance between adhesion and migration, and failures in this regulation can lead to pathologies such as carcinogenesis and metastasis. The actin cytoskeleton has been shown to be an essential component of this regulation. Here we show that microtubules play a role in this regulation as well. Microtubules target epithelial adherens junctions, where they are transiently tethered at sites of cell-cell contact by a web of protein interactions that includes cytoplasmic dynein, PLAC-24 and β-catenin. These tethered microtubules appear to play a key role in the regulation of junction assembly. The number of microtubules targeting mature junctions is relatively small, but is significantly higher during junction assembly. Depolymerization of microtubules or disruption of microtubule dynamics inhibits junction formation. Cytoplasmic dynein is localized to initial points of contact between cells, and microtubules project directly to these dynein patches where they become tethered. Direct inhibition of cytoplasmic dynein function by microinjection of anti-dynein intermediate chain antibodies disrupts the tethering of microtubules and inhibits junction formation. These tethered microtubules may serve as tracks for directed cargo trafficking, and immunocytochemistry with junctional components such as α-catenin and p120catenin suggests that they are deposited proximal to tethered microtubules. However, these tethered microtubules may also serve as tracks for retrograde signalling to convey information about the state of the forming junction to the cell center. Together these data suggest that microtubules tethered at sites of cell-cell contact by cytoplasmic dynein are critical in the regulation the dynamics of intercellular adhesion. *Supported by NIH GM068591.*

### 3D Tissue Architecture and SMRT-dependent Death Resistance

C. Chatterjee,[1] M. Nuth,[1] J. Leight,[2] J. N. Lakins,[1] E. Bernhard,[3] V. M. Weaver[1]; [1]Institute of Medicine and Engineering/Pathology, University of Pennsylvania, Philadelphia, PA, [2]Department of Bioengineering, University of Pennsylvania, Philadelphia, PA, [3]Department of Radiation Biology, University of Pennsylvania, Philadelphia, PA

Apoptosis resistance plays a critical role in tumor progression and treatment responsiveness. We have been studying how cell-ECM interactions modify survival of mammary tumors. We identified laminin-α6β4 integrin-NFκB as an important mechanism that can mediate apoptosis resistance in mammary tissues (Weaver et al., Cancer Cell 2002; Zahir et al., J Cell Biol 2003). We found that the efficacy of NFκB-dependent survival is dramatically enhanced when MECs are grown to form three-dimensional (3D) tissues. Basement membrane (BM)-ligated MECs in both 2D and 3D similarly permit NFκB activation and induction of anti-apoptotic genes (IAP-1, A20). Yet, NFκB activation in MECs in 2D but not in 3D significantly increases expression of multiple stress response genes (ATF2, IL8). Interestingly, we found that treatment with the histone deacetylase inhibitor TSA increases stress gene expression and renders 3D MEC structures apoptotically sensitive; consistent with micro-array data showing that 3D MEC structures repress expression of hundreds of stress-response genes, and our contention that epigenetics modulates NFκB-dependent apoptosis resistance of 3D tissues. Consistently, we found that apoptotically-resistant 3D non-malignant MEC structures and phenotypically-reverted tumors up-regulate expression of the chromatin repressors SMRT/NCoR (RT-PCR, immunoblot), and that knocking down SMRT/NCoR (siRNAs) renders 3D MEC structures highly sensitive to multiple apoptotic insults. Moreover, ectopic expression of SMRT permits tumors and even isolated tumor cells to resist γ-radiation (12Gy), immune-receptor (TRAIL) and chemotherapy (Taxol)-induced apoptosis, and SMRT knockdown up-regulates expression of multiple stress-response genes. These data indicate that 3D tissue architecture may enhance NFκB-dependent survival by repressing cell stress through modulation of epigenetic factors such as SMRT. Because SMRT activity and turnover are modulated by adhesion-dependent signaling phosphorylation (SAPK, ERK), and 3D MECs have blunted ERK and SAPK activity, we are exploring links between 3D, the stress response and SMRT-dependent apoptosis resistance. ### An Isoform-Specific Role for Akt1 in Inhibition of Epithelial-Mesenchymal Transition

H. Irie,[1,2] R. Pearline,[1] D. Grueneberg,[3] M. Hsia,[3] P. Ravichandran,[3] N. Kothari,[3] S. Natesan,[3] J. Brugge[1]; [1]Cell Biology, Harvard Medical School, Boston, MA, [2]Medical Oncology, Dana-Farber Cancer Institute, Boston, MA, [3]Sanofi-Aventis Cambridge Genome Center, Boston, MA

Insulin-like growth factor-I receptor (IGF-IR) signaling has been implicated in the pathogenesis of breast and other human cancers. Akt/PKB kinases are activated downstream of IGF-IR and other growth factors, and regulate cell proliferation, survival and migration. However, recent evidence suggests that the three Akt isoforms contribute differentially to key cellular activities. Here we demonstrate that downregulating expression of two distinct Akt isoforms using short hairpin RNA vectors has dramatically distinct consequences on IGF-IR-induced phenotypic changes in both monolayer and three-dimensional (3D) basement membrane cultures of breast epithelial cells. Downregulation of Akt2 reverts

IGF-I induced morphological alterations in monolayer cultures, and the anti-apoptotic and hyperproliferative effects in 3D cultures. In contrast, Akt1 downregulation promoted neomorphic effects consistent with an epithelial-mesenchymal transition (EMT) with enhancement in migration, formation of invasive structures in 3D cultures, and expression of mesenchymal markers. The alterations induced by Akt1 downregulation were accompanied by enhancement of Erk/MAP kinase activity and constitutive Erk activation in IGF-IR overexpressing cells induced phenotypic changes similar to those observed with Akt1 downregulation. Furthermore, Erk inhibition reversed the enhancement in cell motility caused by Akt1 downregulation. These results indicate that there is a dichotomy in the activities of Akt isoforms, with Akt1 playing a negative modulatory role by suppressing Erk activation and masking induction of EMT, and Akt2 positively affecting cell proliferation and cell survival

**Integrin-specific Mechanisms Regulate Cell Responses to a Provisional Matrix**

H. C. Hsia, L. V. Valenick, S. A. Williams, J. E. Schwarzbauer; Molecular Biology, Princeton University, Princeton, NJ

Connections between the extracellular matrix (ECM) and intracellular compartments occur through integrins and other transmembrane receptors. To dissect the roles of cell adhesive ECM proteins in regulating cell functions, we are using a three-dimensional fibrin-fibronectin matrix, resembling the wound provisional matrix. Fibroblasts adhere and spread on this matrix using α5β1 integrin-fibronectin interactions with concomitant engagement of syndecan-4, a transmembrane proteoglycan receptor that also binds to fibronectin. This interaction promotes cell adhesion, actin stress fiber formation, and activation of focal adhesion kinase (FAK) and Rho GTPase. When the ECM protein tenascin-C is present in the matrix, syndecan-4 binding to fibronectin is reduced which prevents FAK and Rho signaling and promotes extension of filopodia, typical of a motile cell phenotype. Tenascin-C also impacts cell contractility. Fibroblasts induced to express tenascin-C using a recombinant adenovirus were deficient in the ability to contract a fibrin-fibronectin matrix but were rescued by activation of Rho with lysophosphatidic acid. Thus tenascin-C affects cell-matrix interactions and signaling via both paracrine and autocrine mechanisms. Another integrin receptor for fibronectin α4β1 does not naturally support strong cell interactions with a fibrin-fibronectin matrix. Surprisingly, however, α4β1 interactions with this matrix are dramatically enhanced, to levels equivalent to α5β1, when the fibronectin is cleaved by proteases. Fibronectin fragmentation apparently generates new sites for α4β1 binding, an effect that could play an important role in matrix remodeling in vivo. Thus, deposition of additional ECM components, expression of co-receptors for ECM, and cleavage of adhesive proteins are different ways to modulate cell responses to fibronectin matrix.

**The Small-G Protein Rap1 Regulates Breast Acinar Polarity in Human Epithelial Cells**

M. Itoh, C. A. Myers, M. J. Bissell; Life Sciences Division, Lawrence Berkeley National Laboratory, Berkeley, CA

Multiple cellular processes are dysregulated in tumor formation and progression. Although commonly described as a disease of unrestricted cell proliferation, a defining feature of epithelium-derived cancer is the loss of normal tissue architecture. The finely coordinated integration of a numbers of processes including cell-cell and cell-ECM interactions, polarity, survival, and proliferation are required for the maintenance of normal tissue architecture. Dysregulation of any of these processes could disrupt tissue organization and lead to tumor formation and progression. To determine the molecular mechanisms involved in breast tumor progression and reversion, we employed a three-dimensional laminin-rich extracellular matrix (3D lrECM) assay with a human breast tumor progression series, which allows us to investigate tumor progression in the context of relevant tissue architecture. We find that Ras-related small-G protein Rap1 activity plays a role in malignant phenotype of T4-2 human breast cancer epithelial cells. Rap1 activity is up-regulated in malignant T4-2 cells compared to non-malignant counterpart S1 cells in 3D lrECM culture. Additional activation of Rap1 enhances the malignancy of T4-2 cells; cell invasiveness and tumorigenesity *in vivo* is increased by introducing dominant-active Rap1. In addition, cells expressing dominant-active Rap1 escape from growth suppression and structural reorganization by treatment with AG1478 which inhibits EGFR signaling in 3D lrECM. On the other hand, reducing Rap1 activity in T4-2 cells causes reversion to a non-malignant acinar-like phenotype; structures derived from dominant-negative Rap1-expressing T4-2 cells show growth-arrested and polarized acinus-like structures in 3D lrECM similar to those derived from normal mammary epithelial cells. Both ERK and AKT pathways appear to be involved in these phenotypic alterations of T4-2 cells. These results suggest that increased Rap1 activity influences breast tumor progression through loss of organization of tissue architecture.

**Reconstruction of the Mammary Branching Morphogenesis Program in 3D Organotypic Cultures**

A. J. Ewald, Z. Werb; Anatomy, University of California, San Francisco, San Francisco, CA

The mammary gland forms through the invasion and branching of epithelium through a fatty stroma. We have combined in vivo genetic analysis with a 3D culture model of mammary branching morphogenesis to dissect the interactions between growth factor signaling, extracellular matrix (ECM) environment, and ECM modifying proteases during mammary development. We have reconstructed the program of mammary branching morphogenesis in these cultures from long-term time-lapse movies. In response to growth factor signals, we observe epithelial remodeling and compaction, lumen formation through cell death, ductal initiation, extension, and bifurcation. Duct initiation and extension occurs by collective sheet movement rather than migration of individual cells. The branching program is critically dependent on the 3D ECM environment. Equivalent cells in 2D do not exhibit this branching behavior and changing the ECM environment from collagen I to Matrigel dramatically changes branching behavior. The interpretation of the 3D ECM environment and growth factor signal requires protease activity, which we have demonstrated through pharmacological and genetic means. Epithelium from the same mouse, with the same ECM and media, but different protease activity, exhibits completely different branching behavior and final morphology. We next examined matrix metalloproteinase (MMP) -2 and -3 null mice. Previous work from our lab (Wiseman, JCB, 2003) demonstrated that MMP2 was required for primary duct invasion and MMP3 for side branching in vivo. We observe deficient branching in the MMP2 null cultures and normal branching in the MMP3 null cultures, arguing that the cultures model primary invasion. We are currently applying time-lapse confocal analysis and pharmacological inhibition to distinguish the relative contributions of proliferation, cell movement, and matrix degradation during epithelial invasion and bifurcation in normal and MMP deficient mammary epithelium.

### 3-D Mechanical Stress and Matrix-binding Chemokines and Growth Factors: a Mechanism of Autologous Gradient Formation

M. A. Swartz, J. D. Shields, C. E. Helm, M. E. Fleury; Integrative Biosciences Institute, Swiss Federal Institute of Technology (EPFL), Lausanne, Switzerland

Cell migration and organization is largely driven by growth factors and cytokines whose efficacies typically depend on local gradients relative to the cell rather than absolute amounts. Such factors commonly bind to the extracellular matrix to be later released by cells via proteolytic enzymes. We consider here how gradients of matrix-liberated chemokines and growth factors may be shaped by very low levels of 3-D flows and, in doing so, uncover a surprising mechanism for autologous gradient generation that cleverly utilizes the combination of subtle mechanical forces and matrix-binding factors, both of which are common in vivo. Such slow flows, on the order of microns per second, exist between the blood and lymphatic capillaries and mediate the transport of macromolecules from the blood to the tissue. We utilize two in vitro experimental systems: cell migration of cells that home to lymphatics (e.g. dendritic cells and tumor cells), and endothelial capillary morphogenesis. In the latter, we utilize a fibrin-bound VEGF variant that is released proteolytically and show that low levels of interstitial flow can synergistically augment the effects of VEGF on the extent and organization of structure formation, and that flow specifically enhances VEGF liberation from the matrix in response to endothelial cell-derived proteases. We then use computational modeling to demonstrate how these slow flows can bias the cell-secreted protease gradients, which in turn lead to skewing of the resulting morphogen gradient and the creation of increasing (autocrine-derived) gradients. In contrast, diffusion alone can only account for decreasing, symmetric autocrine gradients. This work thus demonstrates a novel mechanism of autologous gradient generation and amplification by subtle and ubiquitous mechanical forces.

### Endocytosis at the Synapse: Clathrin and Endophilin-dependent Mechanisms

H. T. McMahon; Neurobiology Division, MRC Laboratory of Molecular Biology, Cambridge, United Kingdom

Clathrin-coated vesicles are found in synapses after extensive stimulation of exocytosis. By examining the networks of protein interactions and the usage of membrane bending modules (ANTH, ENTH, BAR and N-BAR) in this pathway we discovered that a parallel pathway operates for which the molecules are already discovered, but have been miss-assigned. Thus we can now show a role for endophilin in fast vesicle recycling at the synapse that is independent of AP2 adaptor/clathrin-coated vesicle formation. Use of a dominant negative endophilin inhibits fast vesicle retrieval, as measured by capacitance in goldfish bipolar terminals, but the clathrin pathway compensates with a time constant at least 10 fold slower. We can also show how other BAR domain protein are involved in other vesicle budding pathways. This has led us to try and understand what is so special about coated vesicle formation. Thus I will present a view of the hubs and nodes of the endocytic interactome, how these hubs function and how the network works to generate vesicles of uniform size and high fidelity. ### Connecdenn, an AP-2-Binding Protein Linking DENN Domains to Clathrin-Mediated Trafficking in the Synapse

P. D. Allaire,[1] B. Ritter,[1] J. L. Burman,[1] S. Thomas,[1] A. Denisov,[2] K. Gehring,[2] P. S. McPherson[1]; [1]Neurology and Neurosurgery, Montreal Neurological Institute, McGill University, Montreal, PQ, Canada, [2]Biochemistry, McGill University, Montreal, PQ, Canada

Proteins of the endocytic network interact with each other and with membranes through small peptide motifs and modular protein domains. We now describe a new component of the endocytic machinery, termed connecdenn, which contains multiple motifs for binding the α-ear of the clathrin adaptor protein 2 (AP-2). Connecdenn co-immunoprecipitates and co-localizes with AP-2, and peptide competition studies coupled with nuclear magnetic resonance analysis of the α-ear in a complex with a connecdenn peptide define its interaction with the adaptor. In addition to AP-2-binding motifs, connecdenn contains multiple SH3 domain-binding motifs and interacts with SH3 domains of the synaptic proteins intersectin and endophilin. Connecdenn is highly enriched on neuronal clathrin-coated vesicles (CCVs) and is present in the pre-synaptic compartment of neurons. Overexpression of connecdenn disrupts clathrin-mediated endocytosis. At its N-terminus, connecdenn bears the uncharacterized modular DENN (differentially expressed in normal versus neoplastic tissues) domains, which are evolutionarily conserved and are found in multiple proteins with distinct functions. The DENN domains of connecdenn are responsible for stable interactions of the protein with CCVs stripped of their clathrin coats. We thus provide the first demonstration of a functional role for DENN domains and through connecdenn we link DENN domains to the endocytic machinery.

785

### An SH3 Domain in an Endocytic Protein Binds to Ubiquitin to Regulate Protein-Protein Interactions

L. Hicke, S. D. Stamenova, S. A. Francis; Biochemistry, Molecular Biology & Cell Biology, Northwestern University, Evanston, IL

Ubiquitin is a small protein that becomes covalently attached to other proteins to regulate their quantity, location or activity. In the endocytic pathway, ubiquitination targets cargo proteins for sorting into vesicles and regulates components of the endocytic machinery. To understand how ubiquitin regulates endocytosis, we identified yeast proteins required for receptor internalization that bind to monoubiquitin. Yeast epsins (Ent1 and Ent2) and the Eps15 homologue, Ede1, bind to ubiquitin through well-characterized ubiquitin-binding domains (UBDs). By contrast, yeast Sla1 (CIN85 homologue) and Rvs167 (endophilin/amphiphysin homologue) bind to ubiquitin through novel ubiquitin-binding motifs. Sla1 binds to ubiquitin through one of its three N-terminal SH3 domains. Binding of this domain, SH3-3, to ubiquitin is direct and specific. SH3-3 does not bind to canonical PXXP peptide sequences. The ubiquitin-binding site on the SH3-3 domain is composed amino acids on the hydrophobic groove that is the PXXP binding site in other SH3 domains. One important determinant of ubiquitin-binding is the presence of Phe in a position in the SH3-3 groove that is occupied by Tyr in most SH3 domains, including Sla1 SH3-1 and SH3-2. The third SH3 domain of human CIN85 has a Phe in this key position and also binds to ubiquitin. The CIN85 SH3 domain binds less well than Sla1 SH3-3, suggesting that other features of a SH3 domain are also important in determining ubiquitin affinity. Genetic evidence for functional redundancy of SH3-3 with another protein-protein interaction

domain in Sla1 implies that SH3-3-ubiquitin binding is important for regulation of endocytic network complex formation. We propose that multiple UBD-ubiquitin interactions between different proteins overlap in function with other protein-protein interactions, such as EH (Eps15 homology) domain-NPF and SH3-PXXP, to connect and regulate endocytic proteins at the plasma membrane.

786

**Biochemical and Structural Analysis of the Rab/GEF Interaction**

A. Delprato; Department of Molecular Medicine, University of Massachusetts Medical School, Worcester, MA

Rab GTPases play a critical role in the membrane biology of eukaryotic cells by mediating processes such as vesicle budding, cargo sorting, and vesicular transport as well as the priming, docking, and fusion of vesicles with target membranes. Guanine nucleotide exchange factors (GEFs) are structurally diverse proteins that activate small GTPases by catalyzing the exchange of GDP for GTP. Despite the large number of Rab GTPases and their functional importance in membrane trafficking, remarkably little is known about the structural basis by which Rab GEFs recognize and activate Rab GTPases, or the mechanisms for allosteric regulation of Rab GEF activity. Rabex-5 catalyzes nucleotide exchange on Rab5 and cooperates with other factors to promote endosome fusion. We have previously shown that the catalytic domain of Rabex-5 also catalyzes nucleotide exchange on Rab21, which co-localizes with Rab5 on endosomes. In this study, we have solved the structure of the catalytic helical bundle -Vps9 domain of Rabex-5 in complex with nucleotide free Rab21. The crystal structure of the Rabex-5/Rab21 complex is strikingly similar to the Sec7/Arf GTPase complex and provides critical information regarding the conformational changes that accompany the activation of Rab GTPases as well as the structural basis for Rab recognition by Vps9 domains. We have also identified a potent auto-inhibitory region in Rabex-5 that accounts for the weak exchange activity of the full-length protein.

787

**The Structures of Exo70p and the Exo84p C-terminal Domains: a Common Motif and Implications for Exocyst Architecture**

G. Dong, A. H. Hutagalung, C. Fu, P. Novick, K. M. Reinisch; Cell Biology, Yale School of Medicine, New Haven, CT

The exocyst is a large tethering complex that is required for tethering vesicles at the final stages of the exocytic pathway in all eukaryotes. Here we present the structures of the Exo70p subunit and the Exo84p C-terminal domains of the exocyst complex from *S. cerevisiae*, at 2.0 Å and 2.85 Å resolution, respectively. Exo70p forms an elongated rod of 160 Å in length and 30-35 Å in width. The structure shows a novel fold that is composed of four alpha helical bundles arranged sequentially from N- to C-terminus along the length of the rod. The Exo84p C-terminus also forms a long rod (80 Å) consisting of two alpha helical bundled domains, which unexpectedly has the same fold as the Exo70p N-terminus. Our *in vitro* binding experiments demonstrate that Exo70p interacts with three other exocyst subunits, Sec6p, Sec8p, and Sec10p. Whereas the interaction with Sec6p requires only the third domain, that with Sec8p or Sec10p requires most of the sequence of Exo70p. These extended interaction surfaces for Sec8p and Sec10p on Exo70p, stretching 120-160 Å, suggest that these two proteins are also elongated. Combining knowledge of the high resolution structures of exocyst subunits, low resolution images obtained by electron microscopy, and bioinformatic analysis of all exocyst subunits, we propose that many of the exocyst subunits are comprised of helical "exoblock" modules strung together into long rod-like structures. Finally, our experiments probing the interaction between Exo70p and Rho3 GTPase narrow the Rho3p binding site to the third domain of Exo70p. This Exo70/Rho3 interaction may help to tether the entire exocyst to the plasma membrane. A conserved, positively charged surface patch at the tip of the Exo70p C-terminus may also play a role in membrane association.

788

**Structural Mechanism for Sterol Sensing and Transport by OSBP-related Proteins**

Y. Im,[1] S. Raychaudhuri,[2] W. A. Prinz,[2] J. Hurley[3]; [1]Laboratory of Molecular Biology, NIDDK/NIH, Bethesda, MD, [2]Laboratory of Cell Biochemistry and Biology, NIDDK/NIH, Bethesda, MD, [3]Structural Biology and Cell Signaling, NIDDK/NIH, Bethesda, MD

The oxysterol binding protein (OSBP)-related proteins (ORPs) are conserved from yeast to man and are implicated in regulation of sterol pathways and in signal transduction. The structure of the full-length yeast ORP Osh4 was determined at 1.5-1.9 Å resolution in complexes with ergosterol, cholesterol, and 7-, 20-, and 25-hydroxycholesterol. A single sterol molecule binds in a hydrophobic tunnel in a manner consistent with a transport function for ORPs. The entrance is blocked by a flexible N-terminal lid and surrounded by functionally critical basic residues. The structure of the open state of a lid-truncated form of Osh4 was determined at 2.5 Å resolution. Structural analysis and limited proteolysis show that sterol binding closes the lid and stabilizes a conformation favoring transport across aqueous barriers and transmitting signals. The unliganded structure exposes potential phospholipid-binding sites that are positioned for membrane docking and sterol exchange. Based on these observations we propose a model in which sterol and membrane binding promote reciprocal conformational changes that facilitate a sterol transfer and signaling cycle.

**Pathway and Expression Level-Dependent Effects of Oncogenic N-Ras: $p27^{Kip1}$ Mislocalization by the Ral-GEF Pathway and Erk-Mediated Interference with TGF-β Signaling**

Y. I. Henis,[1] S. Kfir,[1] M. Ehrlich,[1] A. Goldshmid,[1] X. Liu,[2] Y. Kloog[1]; [1]Neurobiochemistry, Tel Aviv University, Tel Aviv, Israel, [2]Chemistry and Biochemistry, University of Colorado-Boulder, Boulder, CO

Overactivation of Ras pathways contributes to oncogenesis and metastasis of epithelial cells in several ways, including interference with cell cycle regulation *via* the CDK inhibitor $p27^{Kip1}$ (p27) and disruption of transforming growth factor-β (TGF-β) anti-proliferative activity. Here we show that at high expression levels, constitutively active N-Ras induces cytoplasmic mislocalization of murine and human p27 *via* the Ral-GEF pathway and disrupts TGF-β-mediated Smad nuclear translocation by activation of the Mek/Erk pathway. While human p27 could also be mislocalized *via* the phosphatidylinositol 3-kinase (PI3K)/Akt pathway, only Ral-GEF activation was effective for murine p27, which lacks the Thr157 Akt phosphorylation site of human p27. This establishes a novel role for the Ral-GEF pathway in regulating p27 localization. Interference with either Smad translocation or p27 nuclear localization was sufficient to disrupt TGF-β growth inhibition. Moreover, expression of activated N-Ras or specific effector loop mutants at lower levels using retroviral vectors induced p27 mislocalization but did not inhibit Smad2/3 translocation,

indicating that the effects on p27 localization occur at lower levels of activated Ras. These findings have important implications for the contribution of activated Ras to oncogenesis, and for the conversion of TGF-β from an inhibitory to a metastatic factor in some epithelial tumors.

790

**Constitutive Activation of MEK/ERK MAP Kinase Pathway Induces Expression and Activity of MMP2, MMP9 and SerpinE2 : Roles in Intestinal Tumorigenesis**

V. Durand, M. Boucher, J. Laine, N. Rivard; Anatomy and Cell Biology, University of Sherbrooke, Sherbrooke, PQ, Canada

Strong evidences exist for the critical involvement of Ras/Raf/MEK/ERK cascade in the regulation of intestinal epithelial cell proliferation. K-*ras*$^{V12G}$ is the most frequently mutated oncogene in colorectal cancer and targeted expression of K-ras$^{V12G}$ in the intestinal epithelium causes activation of the MEK/ERK pathway and tumorigenesis in mice. Moreover, blockade of the MEK/ERK pathway suppresses growth of colon tumors in vivo and overexpression of an active mutant of MEK1 induces transformation of cultured intestinal epithelial cells. However, the mechanisms by which the MEK/ERK cascade induces intestinal epithelial cell tumorigenesis remain to be clarified. Methods. Retrovirus encoding the HA-tagged MEK1 wild type (wtMEK) or a constitutive active mutant of MEK1 (MEK1-S218D/S222D, caMEK) were used to infect normal intestinal epithelial crypt cells IEC-6. Modifications of gene expression were determined with Affymetrix rat microarrays. Expression of specific genes was verified by RT-PCR and western blot. By zymography, we determined matrix metalloprotease (MMP) activities. Results. 1-Microarray data showed that constitutive activation of MEK/ERK cascade induces genes involved in cell adhesion and migration, including serpinE2, tissue plasminogen activator, syndecan1, integrinα6, and represses TIMP2/3 genes and genes involved in cell-cell interaction. 2- RT-PCR and western blot analysis confirm the induction of serpinE2, MMP2 and MMP9 in caMEK expressing cells and zymography studies confirm that elevated MMP2 and MMP9 activities are found in their media. 3-Treatment of caMEK expressing cells with UO126 (inhibitor of MEK1/2; 10 uM) or with MMP2/9 inhibitor IV (20 uM) markedly reduces cell proliferation, foci formation and migration (Boyden chamber) and abolishes expression/activity of serpinE2 and MMPs. Conclusion. Constitutive activation of MEK/ERK cascade regulates the expression and activity of extracellular proteases which may confer growth advantage and invasive capacity to intestinal epithelial cells.

791

**Stat3 Regulation by the Caveolae Protein, Cav-1, in Breast Cancer**

K. L. Albert,[1] R. Arulanandam,[1] A. Vultur,[1] L. Raptis,[1] R. Jove,[2] J. Turkson[2]; [1]Department of Pathology, Queen's University, Kingston, ON, Canada, [2]Moffitt Cancer Center, Tampa, FL

Caveolae are cholesterol-rich, flask-shaped invaginations of the plasma membrane with many roles in the cell including signal transduction. Stat3 is a cytoplasmic signal transducer which, upon stimulation of a large number of receptors, is activated by phosphorylation, then migrates to the nucleus to initiate transcription of genes involved in cell division and survival. Despite extensive evidence on the role of caveolae in signal transduction, their effect upon Stat3 is still obscure. We previously demonstrated that cell-to-cell adhesion, as occurs in confluent cultures, can cause a dramatic increase in Stat3 phosphorylation and activity in cultured normal human breast and carcinoma cells. Examination of the nature of the kinases involved revealed that pharmacological inhibition or genetic ablation of a number of kinases frequently found to be activated in breast cancer such as Src, Fyn, Yes, EGFR, Fer and IGF1-R did ***not*** prevent this Stat3 activation, indicating that these kinases ***individually*** do not play a significant role. Given that many kinase inhibitors were found to be ineffective in clinical trials, we attempted to examine the mechanism of this cell-cell adhesion-mediated, Stat3 activation. Our results indicated that cav-1 transcriptional downregulation results in a dramatic activation of Stat3, which points to cav-1 as an inhibitor of Stat3 activity. Moreover, our data revealed that cell-to-cell adhesion causes a dramatic drop in cav-1 expression, which is followed by a sharp Stat3 activity increase. Therefore, it appears that the activation of a multitude of kinases through cav-1 downregulation at post-confluence might be responsible for the Stat3 activity increase, as well as the absence of Stat3 inhibition through inactivation of specific kinases individually. This work may expose the caveolae as an essential target for the treatment of tumors resistant to multiple kinase inhibitors.

792

**Mechanisms Regulating Oncogenic Signalling by Sphingosine Kinase**

S. M. Pitson; Human Immunology, IMVS, Adelaide, Australia

Sphingosine kinase 1 (SK1) catalyzes the formation of the bioactive lipid sphingosine 1-phosphate, and has been implicated in a number of biological processes in mammalian cells, including enhanced proliferation, inhibition of apoptosis, and oncogenesis. SK1 possesses high instrinsic catalytic activity which can be further increased by a diverse array of cellular agonists. We have begun to understand the molecular mechanisms regulating oncogenic signalling by SK1 by recently demonstrating that; (i) this activation occurs as a direct consequence of ERK1/2-mediated phosphorylation at Ser225, which not only increases catalytic activity, but is also necessary for agonist-induced translocation of SK1 from the cytoplasm to the plasma membrane; (ii) the oncogenic effects of overexpressed SK1 are blocked by mutation of the phosphorylation site despite the phosphorylation-deficient form of the enzyme retaining full instrinsic catalytic activity, and; (iii) SK1 translocation is the key effect of phosphorylation in oncogenic signalling by this enzyme through constitutive localization of the phosphorylation-deficient form of SK1 to the plasma membrane. We now show that calmodulin may play an essential role in regulating the important process of SK1 localisation since disruption of the CaM-binding site of this enzyme ablates its agonist-induced translocation to the plasma membrane.

793

**Role of A-Kinase Anchoring Proteins in cAMP-mediated Schwann Cell Proliferation**

A. L. Asirvatham,[1] C. M. Schworer,[2] D. Heitzman,[2] D. J. Carey[2]; [1]Biology, College Misericordia, Dallas, PA, [2]Weis Center for Research, Geisinger Clinic, Danville, PA

Proliferation of Schwann cells during peripheral nerve development is stimulated by the heregulin/neuregulin family of growth factors expressed by neurons. However, for neonatal rat Schwann cells growing in culture, heregulins produce only a weak mitogenic response. Supplementing heregulin with forskolin, an agent that elevates cyclic AMP levels but has no mitogenic response itself, produces a dramatic increase in the proliferation of cultured Schwann cells. The mechanisms underlying this synergistic effect are not understood, nor is it established if cyclic AMP

elevation is required for Schwann cell proliferation *in vivo*. Characterizing the A-kinase anchoring proteins (AKAPs) in Schwann cells might help identify substrates tethered to and phosphorylated by PKA. Using an RII overlay assay that detects AKAPs, we identified AKAP150 in Schwann cells. Western blot analysis confirmed the presence of AKAP150 and revealed that additional AKAPs, specifically, AKAP95, Yotiao and Ezrin, were also present. Immunoblot analysis indicated that the steady-state expression of AKAP150, AKAP95, and Ezrin was not regulated by treatment with heregulin or forskolin. We also utilized RNA interference technology to specifically knockdown AKAP150 and AKAP95. Transfection with sequence-specific AKAP siRNAs revealed a 97% and 80% reduction for AKAP95 and AKAP150, respectively, after 24 hours. Morphological characterization of Schwann cell AKAPs indicated the presence of nuclear (AKAP95) and membrane-associated (AKAP150) A-kinase anchoring proteins. Preliminary data suggest a role for AKAP95 and AKAP150 in the synergistic response of Schwann cells to treatment with heregulin and forskolin.

794

**Inhibition of Cell Proliferation by Chk Tyrosine Kinase that Localizes to the Nucleus**

Y. Nakayama, A. Igarashi, A. Kawana, N. Yamaguchi; Dept. of Mol. Cell Biol., Grad. Sch. of Pharm. Sci., Chiba University, Chiba, Japan

Csk-family tyrosine kinases, Csk and Chk, are known to suppress the activity of Src-family kinases by tyrosine phosphorylation at the C-terminal tail. Recently, we found that Chk is distributed to the nucleus in addition to the cytoplasm whereas the distribution of Csk is restricted to the cytoplasm. Expression of Chk induced inhibition of cell proliferation. In this study, to investigate the role of Chk in cell proliferation, we analyzed Chk-induced tyrosine phosphorylation in the nucleus and nuclear multi-lobulation. We observed that expression of Chk induced tyrosine phosphorylation in the nucleus in HeLa cells. The experiments with the N-terminal domain-lacking ChkΔN mutant showed that the presence of the N-terminal domain led to a fourfold increase in the cell population exhibiting tyrosine phosphorylation in the nucleus through association of Chk with the nucleus. The tyrosine phosphorylation was induced in a manner that was dependent on the kinase activity of Chk. In situ subnuclear fractionations revealed that Chk induced tyrosine phosphorylation of DNA-associated and nuclear matrix proteins. We also found that the kinase-active but not -inactive Chk mutant inhibited cell proliferation, suggesting that tyrosine phosphorylation induced by Chk plays an important role in Chk-induced inhibition of cell proliferation. Intriguingly, nuclear localizing Chk mutants prolonged S phase of the cell cycle accompanying dynamic nuclear multi-lobulation in a kinase acitvity-independent manner. Cell sorting analysis revealed that nuclear multi-lobulated cells were enriched in late S phase. Multi-lobulated nuclei were surrounded with aberrantly distributed lamin B1, and the multi-lobulation was dependent on microtubules. In conclusion, our findings provide evidence that Chk-induced inhibition of cell proliferation involves the kinase activity-dependent and -independent mechanisms in the nucleus.

795

**Novel Pathway of Rac1, Stat3 and p53 Interaction**

A. Anagnostopoulou,[1] R. Arulanandam,[1] A. Vultur,[1] J. Turkson,[2] R. Jove,[2] L. Raptis[1]; [1]Pathology, Queen's University, Kingston, ON, Canada, [2]Moffitt Cancer Center, Tampa, FL

Stat3 is activated by a number of membrane tyrosine kinases known to be activated in breast cancer. We recently demonstrated that cell-cell adhesion, such as brought about through confluence, can lead to a dramatic increase in Stat3 activity, despite the pronounced growth inhibition. This activation was independent from a number of kinases, including the Src family, EGFR, IGF1-R and Fer, which are often activated in breast cancer. It is also established that cell-cell adhesion may result in the rapid activation of the Rac1 GTPase and that v-Rac can activate Stat3. Our results showed that density did, in fact, stimulate Rac1 activity. However, we also discovered a dramatic increase in total Rac1 protein levels. This increase preceded the Stat3 activity increase by approximately 24 hours, indicating that the density-mediated Rac1 activation could explain the dramatic upregulation in Stat3 activity. Loss of function of the p53 transcription factor is critical for the development of malignancies. However, most natural p53 mutations occur at a late stage in tumor development, and the majority of clinically detectable breast cancers lack p53 mutations. Nevertheless, reduced p53 levels are observed instead. Recent results revealed that Stat3 interacts with the p53 promoter and downregulates p53 transcription. We now demonstrate that the Stat3 increase seen at post-confluence is followed by a dramatic decrease in p53 levels. Furthermore, interrupting Stat3 signaling in densely growing cells through the use of pharmacological inhibitors or genetic ablation up-regulates p53 expression, leading to p53-mediated tumor cell apoptosis. Our findings thus identify Stat3 as a molecular target for reactivating p53 in malignancies such as the majority of breast cancers that still retain an intact p53 gene and could have important implications for the treatment of cancers where inhibitors of tyrosine kinases would be ineffective.

796

**Phosphorylation of Focal Adhesion Kinase At Tyr397, Tyr861, and Tyr925 is involved in Transendothelial Migration of AU-565 Breast Cancer Cells**

S. Earley, G. E. Plopper; Biology, Rensselaer Polytechnic Institute, Troy, NY

The final step of the metastatic cascade involves extravasation of cancer cells through the endothelial lining of blood vessels. AU-565 metastatic breast cancer cells migrate through a bovine lung microvessel endothelial cell (BLMVEC) monolayer, as shown using filter-based migration assays as well as electric cell-substrate impedance sensing (ECIS). Focal adhesion kinase (FAK) is involved in this process, as transient transfection of AU-565 breast cancer cells with siRNA that targets FAK mRNA results in approximately 50% knockdown FAK mRNA expression and diminished transendothelial migration of AU-565 breast cancer cells. Expression of the dominant negative FAK inhibitor FRNK or FAK point mutants (Y397F, Y861F, and Y925F) also results in decreased AU-565 transendothelial migration, whereas overexpression of wildtype FAK or transfection with an empty vector does not. These results demonstrate the importance of FAK signaling in migration of cancer cells across endothelial cell boundaries.

797

**Activated AKT Regulates Nf-κB Activation, P53 Inhibition and Cell Survival in HTLV-1-transformed Cells**

S. Jeong, C. A. Pise-Masison, M. F. Radonovich, H. Park, J. N. Brady; National Cancer Institute, National Institutes of Health, Bethesda, MD

AKT activation enhances resistance to apoptosis and induces cell survival signaling through multiple downstream pathways. Here, we present

evidence that AKT is activated in HTLV-1-transformed cells and that Tax activation of AKT is linked to NF-κB activation, p53 inhibition and cell survival. Overexpression of AKT wild type (WT), but not a kinase dead (KD) mutant resulted in increased Tax-mediated NF-κB activation. Blocking AKT with the PI3K/AKT inhibitor LY294002 or AKT SiRNA prevented NF-κB activation and inhibition of p53. Treatment of C81 cells with LY294002 resulted in an increase in the p53-responsive gene MDM2, further suggesting a role for AKT in the Tax-mediated regulation of p53 transcriptional activity. We show that LY294002 treatment of C81 cells abrogates *in vitro* IKKβ phosphorylation of p65 and causes a reduction of p65 Ser-536 phosphorylation *in vivo*, steps critical to p53 inhibition. Interestingly, inhibition of AKT function did not affect IKKβ phosphorylation of IκBα *in vitro* suggesting selective activity of AKT on the IKKβ complex. Finally, we present evidence that AKT plays a pro-survival function in HTLV-1-transformed cells, which is linked to expression of the Bcl-xL gene. We suggest that AKT plays a role in activation of pro-survival pathways in HTLV-1-transformed cells, through NF-κB activation and inhibition of p53 transcription activity.

798

**Mechanical Regulation of Gene Expression Through the Cysteine-rich Protein 61 (Cyr61) in Smooth Muscle Cells**

D. Zhou,[1] D. Herrick,[2] J. Rosenbloom,[3] B. Chaqour[4]; [1]Dept of Anatomy and Cell Biology, University of Pennsylvania, Philadelphia, PA, [2]Thomas Jefferson University, Philadelphia, PA, [3]University of Pennsylvania, Philadelphia, PA, [4]Dept of Anatomy and Cell Biology, State University of New York (SUNY) Downstate Medical Center, Brooklyn, NY

Application of cyclic strain to in vitro cultured smooth muscle (SM) cells results in profound alterations of the histo-morphometry, phenotype and function of the cells. The onset of this process is characterized by the activation of a cascade of signaling events coupled to progressive and perhaps, interdependent changes of gene expression. In particular, externally applied cyclic stretch to cultured bladder SM cells results in the transient expression of the Cyr61 gene that encodes a cysteine-rich extracelluar matrix-associated heparin-binding protein originally described as a proangiogenic factor capable of altering the gene programs for angiogenesis, adhesion and extracellular matrix synthesis. In this study, we investigated the effects of mechanical stretch-induced Cyr61 on the expression of potential mechano-sensitive Cyr61 target genes and the signaling pathways involved. We showed that suppression of Cyr61 expression with an adenoviral vector encoding an anti-sense oligonucleotide reduced mechanical strain-induced VEGF, $\alpha_v$ integrin and SM α-actin gene expression but had no effect on myosin heavy chain (MHC) isoforms, SM-1 and SM-2. Signaling pathways involving RhoA GTPase, phosphatidyl inositol 3-kinase and cytoskeletal actin dynamics altered stretch-induced Cyr61 and Cyr61 target genes. Reciprocally, adenovirus-mediated overexpression of Cyr61 in cells cultured under static conditions increased the expression of VEGF, $\alpha_v$ integrin and SM α-actin, as well as that of SM-1 and SM-2 isoforms suggesting that the effects of a sustained expression of Cyr61 extend to SM specific contractile function. These effects were dependent on the integrity of the actin cytoskeleton. Together, these results indicate that Cyr61 is an important determinant of the genetic reprogramming that occurs in mechanically challenged cells.

799

**SUMO-1 Modification Influences SnoN to Regulate Myogenesis**

X. Feng,[1,2] K. Wrighton,[2] M. Liang,[1] B. Bryan,[3] K. Luo,[4] M. Liu,[3] X. Lin[2]; [1]Molecular & Cellular Biology, Baylor College of Medicine, Houston, TX, [2]Surgery, Baylor College of Medicine, Houston, TX, [3]Alkek Institute of Biosciences and Technology, Texas A&M University System Health Science Center, Houston, TX, [4]Department of Molecular Cell Biology, University of California, Berkeley, CA

SnoN and Ski control transformation and myogenic differentiation. SnoN/Ski induce transformation by repressing TGF-β signaling, but how they function in myogenesis is largely unknown. Herein we identify SnoN as a target for SUMO-1 modification. Sumoylation occurs primarily at lysine 50 (K50). PIAS family E3 ligases physically interact with SnoN to stimulate its sumoylation. SnoN sumoylation does not alter its stability or its ability to repress TGF-β signaling. However, mutation of SnoN at the K50 sumoylation site enhances its myogenic potential, as ascertained by its increased ability to activate muscle-specific gene expression and enhance myotube formation. Our study identifies a novel role for sumoylation in the regulation of differentiation.

800

**Sodium-Hydrogen Exchanger Isoform 1 (NHE1) Activity Modulation via Physical Interaction by Daxx**

H. Kim,[1] Y. Jung,[1] J. O. Kim,[2] M. G. Lee,[2] E. Kim[1]; [1]School of Bioscience and Biotechnology, Chungnam National University, Daejon, Republic of Korea, [2]Department of Pharmacology and Brain 21 Project for Medical Science, Yonsei University College of Medicine, Seoul, Republic of Korea

NHE1 is a $Na^+/H^+$ antiport protein that regulates the intracellular pH and is activated upon ischemic injury. This study reports that Daxx interacts with NHE1 and modulates its channel activity upon ischemic injury. Both N and C termini of Daxx were mapped as NHE1 binding regions and the cytosolic domain of NHE1 was responsible for the interaction with Daxx. The effect of Daxx-NHE1 interaction was assessed upon ischemic injury in H9c2 cells and in PS120-NHE1, a PS120 cell which stably overexpresses NHE1. Daxx translocates from the nucleus to the cytosol upon ischemia in H9c2 cells. We used Daxx(W621A) mutant which is confined to the cytosol because cytoplasmic Daxx could be able to contact NHE1. Overexpression of Daxx(W621A) increased the NHE1 channel activity in PS120-NHE1 cells. However, Daxx(S667A) which is confined to the nucleus failed to do so. We also have shown that Daxx(W621A) enhances ischemic cell death whereas Daxx(S667A) blocks the ischemic cell death. Thus, our data suggest that Daxx can modulate NHE1 channel activity via nuclear export. [Supported by the grant (CBM2-B211-001-1-0-0) from the Center for Biological Modulators of the 21st Century Frontier R&D Program, MOST, Korea]

**Cell Cycle-regulated Changes in S6K2 Localization and Activity**

M. McDowell,[1] R. Rossi,[2] D. Boyer,[1] J. Pester,[1] A. Montecucco,[2] K. Lee-Fruman[1]; [1]Biological Sciences, California State University Long Beach, Long Beach, CA, [2]Istituto di Genetica Molecolare (IGM) - CNR, Pavia, Italy

Ribosomal S6 kinase 2 (S6K2) is a serine/threonine kinase that was identified based on its homology to S6 kinase 1 (S6K1). The cellular function of S6K2 is yet to be determined, and the localization of endogenous S6K2 protein has not been studied. To better understand the role of S6K2, we carried out detailed temporal and spatial subcellular localization and activity studies via conventional and confocal immunofluorescence as well as with immune complex kinase assay. In HeLa cells S6K2 is found in a punctate pattern both in the cytoplasm and in the nucleus during G1 phase

whereas it is confined to the cell nucleus in S and G2 phases. Immunocolocalization experiments show that a fraction of S6K2 colocalizes with γ-tubulin at the centrosome in G1 phase and at the mitotic spindle poles. Translocation of S6K2 to centrosome during G0-G1 transition is stimulated by various mitogens and is regulated by mammalian target of rapamycin (mTOR). Although cytoplasmic translocation is seen immediately after mitogen is added to cells, S6K2 activity was greater in late G1 and S phases than in early G1 phase, indicating that although S6K2 is confined to the nucleus in S phase it is nevertheless active. We also show that a fraction of S6K2 nuclear foci colocalizes with coilin and fibrillarin at Cajal bodies but not at nucleoli. Our data indicate that subcellular localization of S6K2 is complex and dynamically controlled during the cell cycle. This is the first report of S6K2 as a kinase that associates with the centrosome and Cajal body.

802

**The Multisubstrate Adaptor Protein Gab1 is Involved in VEGF-Induced Signaling and is Required for Endothelial Cell Migration**

M. Laramée,[1] C. Chabot,[1] M. Cloutier,[1] M. Holgado-Madruga,[2] A. J. Wong,[2] I. Royal[1]; [1]Centre de recherche du CHUM, University of Montreal, Montreal, PQ, Canada, [2]Departments of Microbiology and Immunology and Pharmacology, Kimmel Cancer Institute, Philadelphia, PA

VEGF is a multifunctional cytokine involved in the promotion of endothelial cell proliferation, survival, migration, vessel permeability and morphogenesis. The VEGFR2 receptor tyrosine kinase is the main receptor responsible for conveying the biological effects of VEGF in endothelial cells. Upon stimulation, VEGFR2 associates with, and/or leads to the activation of numerous targets including phospholipase C gamma (PLCγ), Phosphatidylinositol 3-kinase (PI3K), Akt, Src and ERK/MAPK which have been involved in the promotion of endothelial cell migration. However, the VEGFR2 proximal signaling events leading to the activation of these pathways in response to VEGF stimulation remain ill-defined. We have identified the Gab1 adaptor protein as a novel VEGFR2 substrate. Gab1 encompasses a PH domain and contains a large number of tyrosine residues and proline-rich regions allowing its interaction with proteins harboring SH2 and SH3 domains. In bovine aortic endothelial cells (BAECs), Gab1 associates in a constitutive manner with Grb2 and PI3K, and in a VEGF-dependent fashion with SHP2, Shc and PLCγ. Gab1 also associates with VEGFR2 in a basal manner, and this association is increased upon VEGF stimulation. Transfection of human microvascular endothelial cells (HMVECs) with Gab1 siRNAs leads to the impaired activation of Src, PLCγ and ERK, but not that of Akt, and to the block of VEGF-induced cell migration. We further show that this is not due to the reduced adhesion, survival or proliferation of the Gab1-depleted cells. Consistent with these data, co-expression of VEGFR2 with a Gab1 dominant negative mutant unable to bind SHP2 (Gab1ΔSHP2) in HEK 293 cells mimics the results obtained with Gab1 siRNAs. Our data thus identify Gab1 and associated SHP2 as novel regulatory components of VEGF-induced signaling pathways and of endothelial cell migration.

803

**Inhibition of Osteoclast Differentiation by Sauchinone, a Lignan from *Saururus chinensis***

K. Han, E. Chang, H. Kim; Seoul National Univesity, Seoul, Republic of Korea

Osteoclasts, multinuclear cells specialized for bone resorption, differentiated from the monocyte/macrophage lineage of hematopoietic cells. Intervention in osteoclast differentiation is considered an effective therapeutic approach to the treatment of bone diseases involving osteoclasts. In this study, we investigated the inhibition effect of sauchinone, a lignan from *Saururus chinensis*, on receptor activator of nuclear factor kappa B ligand (RANKL)-induced osteoclastogenesis. Addition of sauchinone to the osteoclast precursor culture caused a significant decrease in the level of calcitonin receptor, cathepsin K and TRAP mRNA, which are normally upregulated during the osteoclast differentiation dependent on RANKL. RANKL activated the ERK, p38, and NF-κB signal transduction pathways in osteoclast precursor cells, and sauchinone suppressed this activation. Sauchinone also suppressed expression of NFATc1 of differentiated osteoclasts, a master switch in osteoclastogenesis. Taken together, the data demonstrate that sauchinone inhibited RANKL-induced osteoclastogenesis and our findings may be critical for developing a strategy to ameliorate bone resorption diseases.

**P2 Purinergic Receptors Signal to STAT3 in Astrocytes**

K. B. Washburn,[1] J. T. Neary[2]; [1]Pathology, University of Miami, Miller School of Medicine, Miami, FL, [2]Pathology, Biochemistry & Molecular Biology, University of Miami, Miller School of Medicine, Miami, FL

Damage to the central nervous system can evoke a reactive astrogliotic response whereby normally quiescent astrocytes become proliferative. Extracellular ATP is released upon tissue damage and induces DNA synthesis in astrocytes by activating P2 purinergic receptors; however the signaling pathways associated with this response remain to be fully elucidated. Signal Transducer of Activated Transcription 3 (STAT3) has been implicated in reactive astrogliosis and plays an important role in cell cycle regulation by promoting expression of cell cycle and survival genes. Therefore, we investigated whether extracellular ATP and purinergic receptors regulate STAT3 signaling. Using immunoblot analysis, we find that addition of ATP to primary cultures of rat cortical astrocytes increases Tyr-705 phosphorylation of STAT3 and decreases Try-705 phosphorylation of STAT3b (the dominant negative splice variant) in a time-sensitive and concentration-dependent manner. ATP-stimulated Tyr-705 phosphorylation of STAT3 is mediated through P2 receptor activation since suramin, an antagonist of P2 receptors, diminishes this response, whereas 8-(para-sulfo-phenyl)-theophylline (8PSTP), an antagonist of P1 receptors, does not. The P2 class of receptors consists of both G-protein coupled receptors (P2Y) and ligand gated ion channels (P2X). Agonists for both receptor classes stimulate Tyr-705 STAT3 phosphorylation, but only activation of P2Y receptors significantly stimulates Ser-727 phosphorylation of STAT3. Because initial cytoplasmic phosphorylation of tyrosine (Tyr-705)/STAT3 enables dimerization, nuclear translocation, and DNA binding, whereas subsequent phosphorylation of serine (Ser-727) promotes DNA transcriptional activity by STAT3, this implicates P2Y, but not P2X, receptors in DNA transcription of cell cycle regulatory genes which promote DNA synthesis. Our findings indicate that P2 receptors stimulate STAT3 activation and suggest that P2 receptor/STAT3 signaling may play an important role in reactive astrogliosis. This work was supported by the Department of Veterans affairs and the National Institutes of Health.

**JNK-interacting Protein-3 (JIP-3) and Kinesin-1 Control a Signaling Pathway that Leads to Amyloid-*β* Precursor Protein (APP) Phosphorylation and Transport, and to Neuronal Differentiation**

Z. Muresan, V. Muresan; Physiology and Biophysics, Case Western Reserve University, Cleveland, OH

Abnormal phosphorylation of APP is a pathologic feature of Alzheimer's disease. To begin to understand the mechanism of APP phosphorylation, we studied this process in differentiating neurons under normal, physiological conditions. We find that JNK is required for APP phosphorylation at Thr668, leading to localized accumulation of phosphorylated APP (pAPP) in neurites. We show that JIP-3, a JNK scaffolding protein that does not bind APP, selectively increases APP phosphorylation, accumulation of pAPP into processes, and stimulates process extension in both neurons and COS-1 cells. Down-regulation of JIP-3 by siRNA impairs neurite extension and reduces the amount of localized pAPP. The signaling pathway sustained by JIP-3, leading to APP phosphorylation, is qualitatively different from stress-activated JNK signaling pathways. Thus, whereas stress-activated JNK generates pAPP only in the cell body, concomitant expression of JIP-3 restores pAPP accumulation into neurites. Moreover, the JIP-3 pathway activates JNK locally, and does not trigger translocation of pJNK into the nucleus or phosphorylation of nuclear targets such as c-Jun. JIP-3 facilitated APP phosphorylation is upregulated by inhibition of Cdk5, and downregulated by inhibition of GSK 3β. Mechanistically, we found that kinesin-1 directly participates in APP phosphorylation, by bridging the interaction of JIP-3 (which is a kinesin-1 binding protein) with APP. Thus, APP phosphorylation, transport of the generated pAPP into neurites, and neurite extension are interdependent processes controlled by JIP-3/JNK, in a pathway that is modulated by Cdk5 and GSK 3β, and regulated by kinesin-1. We propose that the light chains of kinesin-1 may generally function as scaffolds for assembling signaling complexes.

806

**A Novel Role of P120 Catenin in Regulating Epithelial Cell Growth**

M. Yanagisawa, L. Marlow, J. A. Copland, P. Z. Anastasiadis; Cancer Biology, Mayo Clinic, Jacksonville, FL

E-cadherin is widely considered to be an invasion suppressor. It is also thought to regulate cell proliferation, and is likely important for contact-mediated suppression of cell growth. β-catenin, which binds the C-terminal portion of the cadherin cytoplasmic tail, may mediate these effects as it transactivates the expression of hyperproliferative genes when associated with LEF/TCF transcription factors in the nucleus. The role of p120 catenin on cell proliferation is unclear. Here, we show that p120 depletion affects the growth of E-cadherin-deficient, V12-Ras expressing MDA-MB-231 cells *in vitro*, and *in vivo*. SiRNA-mediated p120 depletion blocked the growth of MDA-MB-231 cells in soft agar and in nude mice, while re-expression of p120 isoforms 1 or 4 rescued the transformed phenotype and tumor growth. Interestingly, colonies grew as tight aggregates in p120 4A re-expressing cells, whereas they were dispersed in control MDA-MB-231 cells, or p120-depleted cells re-expressing p120 isoform 1. Furthermore, activation of Rac in p120-depleted cells rescued cell growth both in soft agar and in nude mice, consistent with a previously reported role of Rac in Ras transformation. Rac activity was blocked in p120-depleted cells and induced by either p120 isoform 1 or 4. Finally, the role of p120 depletion on MAPK and PI3K signaling was also tested. The data strongly suggest a role for endogenous p120 in Ras-mediated epithelial cell transformation and tumor growth.

**Role of $\alpha_v\beta_3$ Integrin in Sphingosine-1-phosphate Receptor Regulated Pro-angiogenic Activity**

L. Wang,[1] J. Lee,[2] H. Sarojini,[2] Q. Zeng,[2] E. Wang,[2] J. Cai,[3] C. Lin,[4] M. Lee[1]; [1]Microbiology and Immunology, University of Louisville Health Science Center, Louisville, KY, [2]Gheens Center on Aging, University of Louisville Health Science Center, Louisville, KY, [3]Pharmacology and Toxicology, University of Louisville Health Science Center, Louisville, KY, [4]Oncology, Georgetown University Medical Center, Washington, DC

Sphingosine-1-phosphate and integrin $\alpha_v\beta_3$ mediated signaling cascades are critical in angiogenic responses. In this report, we show integrin $\alpha_v\beta_3$ and S1P1 receptor form a functional complex in endothelial cells. The interaction between $\alpha_v\beta_3$ integrin and S1P1 receptor is specific because $\alpha_v\beta_3$ and S1P1 association is significant reduced in Lentiviral mediated S1P1 receptor silenced endothelial cells and integrin $\beta_1$ polypeptide does not interact with S1P1 receptor. Also, $\alpha_v\beta_3$ and S1P1 receptor interaction is enhanced upon sphingosine-1-phosphate stimulation and is dependent on Gi heterotrimeric G protein. In addition, sphingosine-1-phosphate treatment induces the FAK and α-actinin associating with $\beta_3$, which is dependent on $G_i$ heterotrimeric G protein and S1P1 receptor. Moreover, sphingosine-1-phosphate induced endothelial chemotaxis and morphogenesis is abrogated by the $\alpha_v\beta_3$ blocking antibody. These data together indicate that $\alpha_v\beta_3$ is a down-stream target of S1P signaling and the activation of $\alpha_v\beta_3$ integrin is critical in S1P-regulated angiogenic responses.

**Maintenance of the Proliferative State in Intestinal Epithelial Cells by Notch1 Signaling**

S. Guilmeau, M. Flandez, L. H. Augenlicht; Oncology, Montefiore Medical Center, New York, NY

**Objective:** To investigate whether Notch signaling is involved in the proliferation and lineage determination of intestinal epithelial cells. **Results:** *In vivo*, Notch intracellular domain 1 (NICD1), was immunolocalized to the nucleus of proliferating crypt cells in mice. Fractionation of the epithelial cells along the crypt-villus axis through the Weiser method also indicated that NICD1 was expressed in the crypt fraction of the duodenum, jenunum and ileum, with low to undetectable levels of NICD1 observed in cells from the villi. *In vitro*, we used two different cell lines that undergo spontaneous differentiation into goblet cells and enterocytes: the 16E clonal derivative of the HT29 cell line and the Caco-2 cell line, respectively. In both cell lines, NICD1 expression, as well as the Notch ligand Jagged1, were down-regulated during differentiation of the cells along either lineage. However, quantitative PCR indicated that the expression ratio of HES1, a key target gene of Notch, standardized to GAPDH, was upregulated by to 2 to 3 fold in fully differentiated cells compared to undifferentiated cells. Moreover, an MTT assay showed that a 48 hour treatment of cells with L,685-458, a gamma-secretase inhibitor (GSI), induced a dose dependent inhibition of 16E and Caco-2 cells proliferation, reaching 60 and 50% respectively, at 10uM of GSI. This growth inhibition was accompanied by a G1 arrest and an increase of cell number in the S phase. Data also suggest that RNA interference of Notch1 expression inhibited proliferation in the Caco-2 cell line. **Conclusion:** Since Notch1 signaling is activated both *in vitro* and *in vivo* in proliferating but not in differentiating cells, and its down regulation reduced proliferation *in vitro*, this pathway might be implicated in the maintenance of intestinal progenitor cells through a HES1 independent pathway.

809

**Divergence of Hedgehog Signaling between Drosophila and Mammals**

M. T. Varjosalo, S. Li, J. A. Taipale; Biomedicum, Molecular/Cancer Biology Program, University of Helsinki, Helsinki, Finland

The Hedgehog (Hh) signaling pathway has conserved roles in development of species ranging from Drosophila to Humans. Responses to Hh are mediated by the transcription factor Cubitus interruptus (Ci; GLIs 1-3 in mammals), and constitutive activation of Hh target gene expression has been linked to several types of human cancer. In Drosophila, the kinesin-like protein Costal2 (Cos2), which associates directly with the Hh receptor component Smoothened (Smo), is essential for suppression of the transcriptional activity of Ci in the absence of ligand. Another protein, Suppressor of Fused (Su(Fu)), acts in parallel to Cos2 and exerts a weak negative influence on Ci activity. Whereas the loss of Cos2 causes constitutive activation of Hh target genes and is embryonic lethal, Drosophila embryos deficient in Su(Fu) develop into viable and fertile adults. We have found that the Smo C-terminal domain that in Drosophila is phosphorylated in response to Hh and binds to Cos2 is not required for mouse Smo function. Conversely, introduction of the Drosophila Smo C-terminal sequences to mouse Smo renders mammalian Hh signaling Cos2 -sensitive. Furthermore, we show that the two closest mouse orthologs to Cos2, Kif7 and Kif27 fail to affect Shh signaling in mouse cells, and that in contrast, RNAi -induced loss of Su(Fu) expression results in a dramatic increase in Shh pathway. Our results indicate that Drosophila and mammalian Hh signaling mechanisms have diverged at the level of Smo, Cos2 and Su(Fu), and that in mammals, the inhibition of the Hh response pathway in the absence of ligand critically depends on Suppressor of Fused.

810

**Disparate Biological Effects of Intracellular Domains of Notch Ligands: Delta1 Induces p21-dependent Growth Arrest and Jagged1 Induces Apoptosis**

V. Kolev,[1] D. Kacer,[1] M. Duarte,[1] I. Graziani,[1] B. Larman,[1] J. Mitchell,[1] R. Soldi,[1] D. Small,[2] T. Maciag,[1] I. Prudovsky[1]; [1]Maine Medical Center Research Institute, Maine Medical Center, Scarborough, ME, [2]Department of Biochemistry, University of New Hampshire, Durham, NH

Notch signaling plays an important role in the regulation of angiogenesis and endothelial cell phenotype. Activation of Notch receptors results in proteolytical cleavage of their intracellular domains, which translocate to the cell nucleus, and act as transcriptional regulators. Recent findings demonstrated that the Notch ligands, Delta and Jagged, also undergo Notch-dependent cleavage of their intracellular domains. Previously we found that soluble extracellular domains of Delta 1 and Jagged 1 inhibit Notch signaling, and induce substrate-dependent multicellular cord formation. To explore the biological effects of the intracellular domains of Jagged1 and Delta1 in the endothelium, we transduced human umbilical vein endothelial cells with Jagged1 and Delta1 intracellular domains. Cells transduced with beta-galactosidase served as a control. Jagged1 intracellular domain expression induced a p53-independent apoptosis manifested by the exposure of phosphatidylserine on the cell surface, DNA fragmentation, and activation of caspase 3. Conversely, Delta1 intracellular domain expression resulted in a non-proliferating senescent-like phenotype characterized by accumulation of p21 and p27. Further studies revealed that the pro-apoptotic effect of the Jagged 1 intracellular domain and cytostatic effect of Delta 1 intracellular domain were not endothelial-specific but manifested in a wide variety of cell types. Interestingly, p21 knockout but not p27 knockout cells were refractory to the antiproliferative effect of the Delta 1 intracellular domain. Mutation analysis demonstrated that the proliferation blockage by the Delta1 intracellular domain did not require either its nuclear localization or the presence of a C-terminal PDZ-binding domain. Both of the Jagged1 and Delta1 intracellular domain-induced phenotypes were abolished by co-expression of constitutively active Notch1. Our data suggest divergent intracellular roles for Jagged 1 and Delta1 Notch ligands and support the bi-directional model of Notch signaling.

811

**Busulfan-Induced Senescence in WI-38 Fibroblasts**

V. B. Probin, Y. Wang, D. Zhou; Pathology and Laboratory Medicine, Medical University of South Carolina, Charleston, SC

Chronic lung fibrosis induced by various chemotherapeutic agents, such as busulfan (BU), is an important dose-limiting factor for cancer therapy. However, the etiology of chemotherapy-induced lung fibrosis remains to be elucidated. For the first time to our knowledge, we show that WI-38 normal human lung fibroblasts incubated with BU (6.25-125 μM) for 24 hr undergo premature senescence, but not apoptosis, in a dose-independent manner. In contrast, incubation with two other chemotherapeutic agents, etoposide and daunorubicin, induces WI-38 cell apoptosis and/or senescence in a dose-dependent way (high dose-apoptosis and low dose-senescence). Induction of WI-38 cell senescence by a low dose of etoposide (20 μM) is mediated via a well-established DNA damage response pathway: transient activation of the p53-p21 pathway followed by sustained up-regulation of $p16^{Ink4a}$ resulting in a permanent G1 arrest, whereas senescent WI-38 cells induced by BU are permanently arrested in G2 phase in association with a prolonged activation of the Erk (p42/44) pathway and expression of $p16^{Ink4a}$ without significant changes in p53, p38 MAPK and JNK phosphorylation. In addition, inhibition of Erk by a specific inhibitor (PD98059 or U0126) significantly inhibits BU-induced senescence in WI-38 cells. Conversely, inhibition of p38 MAPK, JNK, and p53 with their respective inhibitors has no such effect. Upon removing Erk inhibition, BU-treated cells can proceed to DNA synthesis and cell division. These findings suggest that BU is a distinctive chemotherapy that can cause normal lung fibroblast senescence through a unique mechanism. Induction of fibroblast senescence may contribute to the pathogenesis of lung fibrosis after chemotherapy as senescent fibroblasts produce many soluble molecules and cytokines that are important inflammatory mediators. Therefore, a better understanding of the mechanism of BU-induced lung fibroblast senescence could be beneficial to developing new therapeutic strategies that limit normal tissue damage, thereby improving cancer therapy efficacy.

812

**Blockade of PKC Activation by Nur77 during T Cell Receptor-mediated Apoptosis**

H. Youn, H. Kim, B. Kim; Dept Biochemistry and Molecular Biology, Seoul National University College of Medicine, Seoul, Republic of Korea

TCR engagement is likely to invoke the signaling pathways involved in IL-2 production and Nur77-mediated apoptosis in immature T cells. However, little is known about how TCR decodes two conflicting signaling pathways. Nur77 plays important roles in TCR-mediated apoptosis during negative selection. Here we identified PKC as a novel binding partner of Nur77. Upon TCR stimulation, Nur77 was rapidly translocated into cytoplasm and colocalized with PKC in T cells. Nur77 inhibited the catalytic activity of PKC by direct binding to the ATP-pocket in PKC, which ultimately led to the repression of PKC-targeting transcription factors and endogenous IL-2 synthesis. Moreover, Nur77 induction showed

an inverse relationship with IL-2 synthesis in primary thymocytes. These findings reveal an intrinsic function, namely, that Nur77 represses cytokine production during TCR-mediated apoptosis.

813

**Nucleocytoplasmic Shuttling of Pak5 and its Effects on Apoptosis**

S. Cotteret, J. Chernoff; w451, Fox Chase Cancer Center, Philadelphia, PA

p21-activated kinase 5 (Pak5) is an effector for the small GTPase Cdc42 that is known to activate cell survival signaling pathways. Previously, we have shown that Pak5 is localized primarily to the mitochondria, and that it induces resistance to apoptosis by phosphorylating Bad and perhaps other proteins. To study the relationship between Pak5 localization and its effects on apoptosis, we identified sequence elements that regulate the localization of this kinase. Removal of amino acids 30-83 from the N-terminus substantially decreases the fraction of Pak5 in mitochondria, and increases the fraction of Pak5 in the nucleus. Mutation of a newly-identified nuclear export sequence, comprising residues 401-411, augments this effect, whereas removal of an N-terminal NLS (amino acids 5-10) abolishes it. Blockade of nuclear export with Leptomycin B causes endogenous Pak5 to accumulate in the nucleus, indicating that this kinase shuttles between the nucleus and mitochondria. Pak5 mutants that cannot localize to mitochondria do not confer protection against apoptosis induced by DNA damage. These findings suggest that Pak5 has critical mitochondrial targets that mediate its anti-apoptotic effects. Moreover, reduction of endogenous Pak5 expression in neuroblastoma cells increases their sensitivity to apoptosis. These results show that the subcellular localization of Pak5 is regulated by an interplay between mitochondrial and nuclear targeting motifs, and that its localization is vital to its effects on cell survival.

814

**Biological Effects of Par6 Over-expression in Mammary Epithelia**

M. E. Nolan,[1,2] S. Basu,[1] S. K. Muthuswamy[1]; [1]Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, [2]Genetics Program, Stony Brook University, Stony Brook, NY

Mammary epithelial cells line the ducts of the mammary gland and possess apical-basal asymmetry, referred to as cell polarity. This is essential for epithelial function and it is also thought to play a role in growth control of resting tissue. Recent studies have identified three protein complexes, the Par3/Par6/aPKC complex, Scribble/Lgl/Dlg complex and the Crumbs/PALS1/PATJ complex that act in a hierarchal manner to establish cellular architecture. However, regulation of apical-basal polarity in other contexts such as disease is poorly understood. As loss of epithelial cell architecture and re-initiation of proliferation are common features of early hyperplastic lesions, it is becoming increasingly important to decipher the underlying molecular mechanisms that initiate disruption of apical-basal polarity. Recent evidence suggests that alterations in the polarity machinery may contribute to oncogenesis. Loss of LKB1 (Par4) and Dlg5 are predisposition factors for human cancer and the human papillomavirus protein E6, targets scribble for degradation. It has also been shown that Par6 cooperates with RacV12 to transform fibroblasts. Par6 is thought to play an important role in connecting the structural components of the polarity machinery with cellular signaling pathways. Through its PDZ and CRIB domains it interacts with aPKC, Par3 and CDC42. In addition, Par6 has been shown to interact with Crumbs and Scribble complexes. It is not well understood how these interactions are regulated to provide the multiple functions of Par6. In order to investigate Par6 function in the context of polarized epithelia, we use a non-transformed mammary epithelial cell line (MCF-10A). MCF-10A cells require exogenous EGF for growth and form acini with distinct architecture when cultured on collagen and laminin. We are using both the 3D cell culture system and tradition cell culture to investigate the biological and signaling effects of Par6 overexpression in MCF-10A cells.

815

**Regulation of BAD Serine Phosphorylation by the TWEAK-Fn14 Ligand-Receptor System Induces BCL-XL and BCL-W Protein Expression in Invasive Glioma Cells**

N. L. Tran, S. P. Fortin, B. A. Savitch, W. S. McDonough, M. E. Berens; Neurogenomics, Translational Genomics Research Institute, Phoenix, AZ

Biological hallmarks of glioblastomas multiforme (GBM) include a proclivity for local invasion into the adjacent normal brain tissue and the rarity of systemic metastasis. Invasive GBM cells escape surgery and display resistance to chemotherapeutic- and radiation-induced apoptosis. Recently, we described a transmembrane receptor, fibroblast growth factor-inducible 14 (Fn14), whose level of expression correlates with migrating glioma cells in vitro and with invasive high-grade glioma clinical specimens in vivo. We showed that TWEAK-stimulated glioma cells had increased cellular resistance to cytotoxic therapy-induced apoptosis via NF{kappa}B-mediated up-regulation of BCL-XL and BCL-W mRNA expression (Tran et al. JBC 2005). Here, we show that activation of the TWEAK-Fn14 ligand-receptor system leads to rapid stabilization of BCL-XL and BCL-W proteins via phosphorylation of the anti-apoptotic BAD protein. Phosphorylation of BAD following Fn14 activation occurs on serine 136 and 155 through two independent signaling mechanisms. Fn14-mediated BAD serine 136 phosphorylation is dependent on Akt signaling, whereas, BAD serine 155 phosphorylation is dependent upon p90RSK1 activation. In addition, Fn14 activation induces Erk1/2 phosphorylation in a time-dependent manner; inhibition of Erk1/2 phosphorylation by PD98059 (an inhibitor to upstream MEK1/2 function) suppresses Fn14 induced p90RSK1 phosphorylation. Moreover, depletion of p90RSK1 or inhibition of Akt function by dominant-negative Akt protein results in loss of BAD serine 155 and 136 phosphorylation, respectively, and subsequently enhanced glioma cell sensitivity to cytotoxic-therapy induced apoptosis. We hypothesize that the Fn14 protein functions, in part, to enhance invasive glioblastoma cell survival. Understanding the function and signaling of the TWEAK-Fn14 ligand-receptor system may lead to development of novel therapies to therapeutically target invasive glioma cells.

816

**Signaling Network Measurements as Quantitative Predictors of Cytokine-Induced Cell Death**

S. Gaudet,[1] K. A. Janes,[2] J. G. Albeck,[1] D. A. Lauffenburger,[2] P. K. Sorger[1]; [1]Biology, Massachusetts Institute of Technology, Cambridge, MA, [2]Biological Engineering Division, Massachusetts Institute of Technology, Cambridge, MA

There exists only limited understanding of the strategies cells use to process conflicting cytokine stimuli and regulate responses such as apoptosis. In many cell types, apoptotic responses to cytokines, such as tumor necrosis factor (TNF), can be attenuated by growth factors, such as epidermal growth factor (EGF) and insulin. Network-level understanding of signaling induced by these stimuli requires data on a wide variety of biochemical processes. No single existing technology can gather such a heterogeneous collection of data on a large scale. Using kinase activity assays,

quantitative immunoblots, antibody microarrays, and flow cytometry, we build a systematic signaling dataset that could support the construction of predictive models of signaling networks. Time-dependent signaling profiles were determined in HT-29 human colon carcinoma cells treated with multiple concentrations of TNF in combination with EGF or insulin. The reproducibility, internal consistency, and accuracy of our signaling measurements were validated experimentally to fuse the data into a single self-consistent compendium of over 10,000 cell-signaling and response measurements. Using this compendium, we built partial least squares regression (PLSR) models that predict apoptosis with remarkable accuracy, given signaling data as the input. The accurate predictions of the models allowed us to quantify the information content in the compendium and mine the data for biological insights into the control of apoptotic responses. Our principal finding is that EGF and insulin protect cells from TNF-induced cell death through different means_EGF reduces signaling along a stress-death axis defined by the PLSR model, whereas insulin antagonizes TNF-induced apoptosis by triggering an orthogonal set of prosurvival signals. This work illustrates how large datasets of signals and responses can be analyzed to reveal how protein networks control cellular responses, like apoptosis.

817

**Stereology of the Leydig Cells in Chick Testes during Ontogenic Development**

E. C. Soria,[1] G. Gonzalez-Moran[2]; [1]Patología, Instituto Nacional de Cardiología, Distrito Federal, Mexico, [2]Biologia Comparada, Universidad Nacional Autonoma de México, Distrito Federal, Mexico

The aim of this work was to analyse the ultrastructural changes and variations in the number and size of Leydig cells in testes of *Gallus domesticus* during ontogenic development. Changes were studied on day 8 and 13 of embryonic development, on the day of hatching, 2 and 7 months and 2 years after hatching. Left testes were obtained in all cases, and immediately fixed and embedded in Epon and semi-thick sections were morphometrically measured under light microscopy, using stereologic methods. After that, ultra-thin section of the same material were contrasted with uranyl acetate and lead citrate and examined in a Zeiss EM 10 microscope. Histomorphometric and ultrastructural result indicated that testes of chick from days 8 and 13 of embryonic development show scarse Leydig cells. These cells showed scanty cytoplasm with few lipid droplets and organelles, mainly polyribosomes, rough endoplasmic reticulum cisternae and mitochondria with transversal cristae. In contrast, testes from newly-hatched, immature and aged animals showed numerous Leydig cells arranged in groups or cords characterized by the presence of abundant lipid droplets, mitochondria with tubular cristae and numerous cisternae of smooth endoplasmic reticulum in the cytoplasm. In all these groups of animals there is an increase in the number of Leydig cell, but the size of individual Leydig cells remains relativity constant. In contrast, the increase in volume density of the cords of the Leydig cells in adult chick is due to the enlargement of the individual Leydig cells as compared to the elevation in their cellular number.

818

**Role of TAK1-MKK6-p38 Pathway for NFATc1 Induction and NFκB Transactivation in Osteoclast Differentiation**

H. Huang, J. Ryu, J. Ha, E. Chang, Z. H. Lee, H. Kim; Department of Cellular and Developmental Biology, Institute of Dentistry, College of Dentistry and Brain Korea 21 Program, Seoul National University, Seoul, Republic of Korea

Receptor activator of nuclear factor kappaB (NF-κB) ligand (RANKL) is an essential factor for osteoclast differentiation from bone marrow hematopoietic progenitors. It has been demonstrated that p38 MAPK activity is important for osteoclast differentiation induced by RANKL. In this study we aimed to determine the specific contribution of the signal transduction by this MAPK to osteoclast differentiation. Initially, we investigated the expression levels of signaling molecules lying upstream of p38 MAPK. We found that transforming growth factor-activated kinase 1 (TAK1), MAPK kinase 3 (MKK3), and MKK6 increased by RANKL in early stage of osteoclastogenesis from primary bone marrow cells. This increased expression in p38 upstream components led to enhanced p38 activation. Next, we examined effects of these signaling components on osteoclast differentiation and regulation of NFATc1 and NFκB, transcription factors critically involved in osteoclastogenesis. Retroviral transduction of dominant-negative (DN) forms of TAK1 and MKK6 but not MKK3 reduced osteoclast differentiation. Transduction of TAK1-DN and MKK6-DN and treatment with the p38 inhibitor SB203580 attenuated NFATc1 induction by RANKL. TAK1-DN, MKK6-DN, and SB203580, but not MKK3-DN, also suppressed RANKL stimulation of NFκB transcription activity in p65 phosphorylation-dependent manner without affecting DNA site binding. These results indicate that TAK1 and MKK6 constitute the p38 signaling pathway to participate to osteoclast differentiation through p65 phosphorylation and NFATc1 induction in response to RANKL and that MKK6 and MKK3 have differential roles in osteoclastogenesis from bone marrow precursors.

## Apoptosis I (819-844)

819

**Ionizing Radiation Induces Caspase-Dependent but Chk2- and p53-Independent Apoptosis in Drosophila melanogaster**

A. E. Wichmann,[1] B. R. Jaklevic,[2] T. T. Su[1]; [1]Molecular, Cellular and Developmental Biology, University of Colorado, Boulder, CO, [2]Molecular and Cell Biology, University of California, Berkeley, CA

In *Drosophila melanogaster*, ionizing radiation (IR) induces apoptosis in the imaginal discs of larvae, typically assayed at 4-6 hours after exposure to a $LD_{50}$ dose. In null mutants of *Drosophila Chk2* or *p53*, apoptosis is severely diminished in these assays, leading to the widely-held belief that IR-induced apoptosis is dependent on *Chk2* and *p53* in *Drosophila*. Here we more closely investigate the dynamics of the apoptotic response and show that IR-induced apoptosis does occur in the imaginal discs of *Chk2* and *p53* mutant larvae, albeit with a significant delay. We demonstrate that this is a true apoptotic response, as it requires caspase activity and the chromosomal locus that encodes the pro-apoptotic genes *reaper*, *hid* and *grim*. We also show that *Chk2*- and *p53*-independent apoptosis is IR-dose dependent and is therefore possibly triggered by a DNA damage signal. We conclude that *Drosophila* has *Chk2*- and *p53*-independent pathways to activate caspases and induce apoptosis in response to IR. This work establishes *Drosophila* as a model for *p53*-independent apoptosis, which becomes an important pathway for inducing cell death in *p53*-deficient cancer cells.

820

**Okadaic Acid Induces a Caspase-Independent Death in Senescent Human Diploid Fibroblasts**

C. P. Davis, K. Hubbard; Department of Biology and The Graduate School and University Center, CUNY Program in Biology, The City College, CUNY, New York, NY

Apoptotic death occurs throughout life. When disrupted cells die prematurely and diseases such as Alzheimer's or Parkinson's result. Certain cancers also arise when cells do not die by apoptosis. Incidentally, Alzheimer's and cancer are prevalent diseases affecting the aging community and understanding the relationship between aging and disease is of importance. For this reason we use senescent human diploid fibroblasts as a model to study aging. Senescent cells have reached their proliferate limit and no longer divide. Gene expression becomes altered, and morphological changes are evident. Due to the changes seen in these cells, we set out to determine whether senescent WI38 fibroblasts can undergo apoptosis and what apoptotic pathway(s) are used. When young, growth-arrested and senescent WI38 fibroblasts are challenged with okadaic acid, senescent WI38's die in a caspase-independent manner whereas initiator caspase-9 and effector caspases-3, -6 are activated in young and $G_0$ cells. Although the caspases are not activated in senescent cells, nuclear substrates specific for caspases are cleaved. DFF45 levels are lowered in senescent cells treated with OA, but the levels remain the same in young and $G_0$ cells. Caspase substrate α-fodrin is cleaved in young, $G_0$ cells but not senescent cells. Propapoptotic Bcl-2 family member Bak was upregulated in all three-growth states, implicating the mitochondrial pathway in apoptotic death. Understanding the apoptotic mechanism enables us understand the reasons for the prevalence of certain diseases in the older population. It may also serve as a means to one day develop effective drugs for the individuals diagnosed with age-related diseases.

821

**Caspase-6 Like Activity in Differentiating Lens Cells is Due to the Proteasome**

A. J. Zandy, S. Bassnett; Ophthalmology, Washington University, St. Louis, MO

During lens fiber cell differentiation, all intracellular organelles including nuclei, mitochondria, endoplasmic reticulum and Golgi are degraded. This provides a transparent fiber cell cytoplasm through which light can pass. The morphological changes that occur during this process are strongly reminiscent of those that occur during programmed cell death, including chromatin condensation and the generation of fragmented DNA with 3'-OH tails. Furthermore, caspase-6-like activity is markedly elevated when organelle breakdown commences (Foley et al. JBC 279(31) 32142-50). Based on these observations, it is widely presumed that the cell death machinery, including the caspase proteases, is responsible for organelle degradation. To test the role of caspases directly, we examined lenses lacking caspase-3, -6 or -7. Contrary to previous reports, we found that these executioner caspases were not required for organelle degradation. Moreover, the rate of cleavage of VEID-AMC (a caspase-6 substrate) was indistinguishable in wildtype and caspase-6 null animals, demonstrating that this activity was not due to caspase-6. We proceeded to identify the lens VEIDase. Using gel filtration, we found that the VEIDase was large (or part of a large (~700 kD) complex). The VEIDase was also inhibited by MG132, NLVS, and clasto-Lactacystin β-lactone, three drugs known to block the proteasome. Finally, immunoprecipitation of the proteasome from lens lysates effectively depleted VEIDase activity. We conclude that the lens VEIDase activity is most likely due to the caspase-like domain of the proteasome. Ongoing studies will evaluate the role of the proteasome in the organelle degradation process.

822

**Reduction of Apoptosis by Differential Inhibition of Caspases - How Xenon Protects Cells**

C. Petzelt; Exp. Anesthesiology, University Hospital Charité, Berlin, Germany

Xenon is probably an ideal neuroprotectant. In view of its outstanding non-toxicity and extraordinary potential for protection it is approaching the gold standard for such application. Up to now, cellular death was measured by the release of lactate dehydrogenase (LDH). Here we show that prevention of activation of late caspases may be the main target for xenon. Apoptosis was induced in rat cortical neurons by hypoxia or staurosporine and LDH release or activation of caspases 1 - 10 was determined. If neurons were pretreated with xenon, cell damage was reduced. Can such a pre-treatment of cells be retained over time? When neurons were treated with xenon for one hour, maintained under normal conditions for various intervals, and then exposed to the insult, cells retained the xenon-effect for up to 4 hours. A similar result was found when cells were post-treated with xenon. By analysing the caspase cascades three groups of caspases could be identified according tho their sensitivity to xenon: The early caspases 8 and 9 are insensitive to xenon. They are activated by the insult and such activation cannot be prevented. The "intermediary" signalling caspases 1,4,5 are reduced in their activation, and the activity of the late the caspases 3 and 7 is almost completely inhibited. These results reinforce the usefulness of xenon for many clinical situations where either an upcoming damage may become probable and therefore justify the preventive use of xenon, or where the damage may have occurred already but where the time window may still allow therapeutic intervention after the insult.

823

**β-lapachone, a DNA Topoisomerase Inhibitor Induces Growth Inhibition and Apoptosis in Bladder Cancer Cells by Modulation of Bcl-2 Family and Activation of Caspases**

J. Lee,[1] D. Choi,[1] H. Chung,[1] H. Seo,[1] Y. Choi[2]; [1]Department of Biochemistry, Busan Science Academy, Pusan, Republic of Korea, [2]Department of Biochemistry, Dong-Eui University College of Oriental Medicine, Pusan, Republic of Korea

β-lapachone is a quinone obtained from the bark of the lapacho tree (*Tabebuia avellanedae*) in South America, which is kwon as a DNA topoisomerase inhibitor. In this study, we report that β-lapachone inhibits the cell growth of human bladder carcinoma cell line T24 and provide a molecular understanding of this effect. The results showed that β-lapachone inhibited the viability of T24 by inducing apoptosis, which could be proved by formation of apoptotic bodies and DNA fragmentation. RT-PCR and immunoblotting results indicated that treatments of cells with β-lapachone resulted in a down-regulation of anti-apoptotic Bcl-2 member and up-regulation of pro-apoptotic Bax expression. β-lapachone-induced apoptosis was also associated with a proteolytic activation of caspase-3 and caspase-9, inhibition of IAP family expression, and degradation of poly (ADP-ribose) polymerase (PARP), phospholipase C-γ1 and β-catenin protein. However, Fas and FasL levels were inhibited by β-lapachone treatment in a concentration-dependent manner. Taken together, our study suggests that β-lapachone-induced apoptosis in T24 cells is mediated, at least in part, by the mitochondrial-signaling pathway.

824

**Lipopolysaccharide Induced Caspase-independent Apoptosis of Human Lung Epithelial Cells**

P. S. Tang,[1,2] M. E. Tsang,[1,2] M. Lodyga,[1,2] X. Bai,[1] A. Miller,[1] B. Han,[1] M. Liu[1,2]; [1]Division of Cellular and Molecular Biology, University Health Network Toronto General Research Institute, Toronto, ON, Canada, [2]Institute of Medical Science, University of Toronto, Toronto, ON, Canada

Caspase-independent cell death has drawn increasing attention. In the present study, we found that LPS accelerated spontaneous death of human lung epithelial A549 cells after they became confluent, in a serum- and cell density-dependent manner. The apoptotic features were demonstrated by TUNEL assay, DNA laddering and Annexin V staining. However, two commonly used pan-caspase inhibitors, zVAD.fmk and BOC-D.fmk, failed to abolish the apoptosis. In contrary, two cathepsin B inhibitors, Ca074-Me or N-1845, reduced cell death significantly. A time-dependent activation of cathepsin B, but not caspase 3, was observed in both control and LPS-treated confluent cells. Although LPS did not further activate cathepsin B or enhance its release from lysosome to cytosol, it induced expression and translocation of apoptosis inducing factor from mitochondria to nucleus as demonstrated by immunofluorescence. LPS-induced apoptosis was significantly attenuated by a free radical scavenger, N-acetyl L-cysteine. Interference of microfilament with cytochalasin D, or lipid raft formation with filipin or methyl-β-cyclodextrin, also reduced apoptosis significantly. These data imply that cells undergo spontaneous cell death mediated by cathepsin B; internalized LPS may trigger release of mitochondrial contents via reactive oxygen species to speed up this caspase-independent apoptosis.

**Degradation of Arrestins by Caspases in Apoptotic Cells**

S. KOOK,[1] J. L. Benovic,[2] V. V. Gurevich,[1] E. V. Gurevich[1]; [1]Pharmacology, Vanderbilt University, Nashville, TN, [2]Microbiology and Immunology, Kimmel Cancer Center, Thomas Jefferson University, Philadelphia, PA

G protein-coupled receptors (GPCRs) activate numerous cellular signaling pathways via their interaction with heterotrimeric G proteins. GPCRs undergo homologous desensitization by a two-step mechanism: phosphorylation of activated receptors by G protein-coupled receptor kinase followed by arrestin binding. Arrestins shield cytoplasmic surface of GPCRs thereby "uncoupling" them from G proteins and effectively terminating G protein-mediated signaling. Although traditionally thought of as mediating GPCR desensitization, arrestins have now been shown to orchestrate GPCR internalization via coated pits and participate in their recycling and also serve as scaffoldings assembling signaling complexes with protein kinases that link GPCRs to alternative G protein-independent signaling pathways. There are two ubiquitously expressed arrestin subtypes, arrestin2 and arrestin3, that interact with numerous GPCRs. In the present study, we demonstrate the cleavage of arrestin2/3 during etoposide-induced apoptosis in Rat-1 cells. Treatment with the caspase inhibitor, zVAD-fmk prevented arrestin2/3 cleavage. Arrestin cleavage occurs relatively early in apoptosis: it is detectable within 6 h and is prominent after 12 h of etoposide treatment. *In vitro* cleavage studies with purified arrestins and recombinant caspases demonstrated that arrestins 2 and 3 are preferentially cleaved by different caspases. In cells, arrestin form complexes with activated phosphorylated GPCRs. In vitro experiments with purified proteins showed receptor binding accelerates the rate and changes the pattern of arrestin2 cleavage, likely due to the well-documented difference in the conformation of free and receptor-bound arrestins. Cell fractionation studies showed that the arrestin2 fragments that are generated by etoposide treatment are localized predominantly to the mitochondria. In addition, overexpression of arrestin2 in Rat-1 cells protected against etoposide-induced apoptosis. These data demonstrate for the first time that arrestins are caspase substrates during apoptosis. Caspase cleavage of free and/or receptor-bound arrestin may represent an important mechanism for the regulation of cell death and survival.

826

**Caspase-Independent Nucleosomal DNA Fragmentation by Endonuclease G under Sustained Endogenous Oxidative Stress**

Y. Ishihara,[1] M. Iwasaki,[1] N. Shimamoto[2]; [1]Department of Biology, Osaka University, Osaka, Japan, [2]Faculty of Pharmaceutical Sciences at Kagawa Campus, Tokushima Bunri University, Kagawa, Japan

The increased production or decreased elimination of reactive oxygen species inside cells induces oxidative stress, which sometimes causes cell demise, apoptosis or necrosis. We have previously shown that inhibition of both catalase and glutathione peroxidase activities by 3-amino-1,2,4-triazole (ATZ) and mercaptosuccinic acid (MS) results in endogenous oxidative stress and apoptotic cell death in rat primary hepatocytes, and that caspase family cannot function in this apoptotic cell death because of the oxidized sulfhydryl groups in caspase itself. In addition, the cleavage of inhibitor of caspase-activated deoxyribonuclease (ICAD) was not detected, which indicated no role of caspase-activated deoxyribonuclease (CAD). However, DNA fragmentation was distinctively observed, indicating involvement of other deoxyribonucleases (DNases) than CAD. Therefore, in this study, we investigated DNA fragmentation factor(s) acting on this process of cell death. Pan-DNase inhibitor, aurintricarboxylic acid (ATA) completely inhibited DNA fragmentation induced by treatment with ATZ+MS, showing clear participation of DNase in this DNA fragmentation. Thus, of the DNases we focused on endonuclease G (EndoG), which is reported to act in a caspase-independent manner. Rat EndoG cDNA was cloned from a rat liver cDNA library. Recombinant EndoG activity was inhibited by ATA. However, its activity was not inhibited even at 10 mM hydrogen peroxide. Furthermore, EndoG translocated from mitochondria to nuclei in response to ATZ+MS stimuli. Applying RNA interference method to hepatocytes, mRNA levels of EndoG were almost completely suppressed and the amount of EndoG protein decreased to approximately a half level of untreated cells. Under this condition, DNA fragmentation was significantly suppressed. These results indicate that EndoG was responsible, at least in part, for DNA fragmentation under sustained endogenous oxidative stress conditions induced by treatment with ATZ+MS.

827

**Specific Phosphorylation of c-FLIP$_S$ Determines Its Ubiquitylation and Rapid Turnover**

A. Kaunisto,[1,2] V. Kochin,[1,2] M. Poukkula,[1,2] V. Hietakangas,[1,3] K. Denessiouk,[4] T. Katajamäki,[1,4] M. S. Johnson,[4] L. Sistonen,[1,3] J. E. Eriksson[1,2]; [1]Turku Center for Biotechnology, Turku, Finland, [2]Department of Biology, University of Turku, Turku, Finland, [3]Department of Biology, Åbo Akademi University, Turku, Finland, [4]Department of Biochemistry and Pharmacy, Åbo Akademi University, Turku, Finland

The two c-FLIP proteins, c-FLIP$_S$ and c-FLIP$_L$, modulate death receptor responses by docking to the activated death receptor complex and preventing the formation of active caspase-8 homodimers. The two splice variants have characteristic structural features, with distinct roles in death receptor signaling. Here, we show that both c-FLIP proteins are ubiquitylated and subsequently degraded by the proteasome. However, c-FLIP$_S$ has a dramatically shorter half-life than c-FLIP$_L$, suggesting that distinct mechanisms regulate the turnover of the isoforms. We have identified two

lysines, 192 and 195 (C-terminal to the DED domains), as principal targets for ubiquitylation in c-FLIP$_S$. Surprisingly, the mere presence of these lysines is not a sufficient determinant for their ubiquitylation, as they are found in both isoforms, but ubiquitylated only in c-FLIP$_S$. The efficient ubiquitylation of the target lysines in c-FLIP$_S$ requires the C-terminal splicing tail unique to c-FLIP$_S$. Molecular modeling suggests that the C-terminal tail is crucial for correct positioning and subsequent ubiquitylation of the target lysines. While both c-FLIP proteins are phosphorylated, the phosphorylation of c-FLIP$_S$ is more pronounced. We show that aspartate mutation of a specific phosphorylation site inhibits the ubiquitylation of c-FLIP$_S$, thereby stabilizing the protein. Specific phosphorylation site was confidently determined using thin layer chromatography of *in vivo* $^{32}$P-labeled c-FLIP$_S$ phosphopeptides and MALDI MS. In conclusion, our study reveals isoform-specific control of the ubiquitylation and stability of c-FLIP proteins and shows that the turnover of c-FLIP$_S$ is regulated in a concerted manner by phosphorylation-dependent ubiquitylation. Given the fast turnover of c-FLIP$_S$, this mode of regulation provides a way to rapidly activate or deactivate the inhibitory effect of c-FLIP$_S$ in both apoptotic and inflammatory death receptor signaling.

828

**Rac1 Regulates Apoptosis via N-terminal C-Jun Kinase in IEC-6 Cells**

S. Jin, R. M. Ray, L. R. Johnson; Department of Physiology, University of Tennessee Health Science Center, Memphis, TN

Rac1, a member of the Rho family of small GTPases, is linked to the regulation of the cellular cytoskeleton by inducing the remolding of the actin cytoskeletal structures. Recent evidence suggests that Rac1 also plays an important role in programmed cell death (apoptosis). Previous data from our laboratory led us to investigate the possible involvement of Rac1 in TNF-α-induced apoptosis in intestinal epithelial cells. In the current study, we show that 1) Rac1 is activated by TNF-α within 1 minute and peak level is achieved by 10 minutes and remains elevated for 30 minutes. 2) Inactivation of Rac1 by expression of DN-Rac1 or Rac1 specific inhibitor NSC23766 decreases DNA fragmentation. 3) Inhibition of Rac1 decrease N-terminal c-Jun kinase (JNK) activation. 4) Caspase 3, 8, and 9 activities are decreased in response to Rac1 inhibition. Thus, Rac1 modulates JNK-mediated apoptotic signaling in IEC-6 cells.

829

**Notch Antagonizes the JNK Signaling Pathway by Interfering with the Scaffold Function of JIP1**

J. Kim,[1] M. Kim,[1] K. Kim,[1] H. Yun,[1] J. Chae,[1] S. Hwang,[1] T. Chang,[2] H. Park,[3] K. Lee,[4] P. Han,[4] S. Cho,[5] T. Kim,[6] E. Choi[1]; [1]National Creative Research Initiative Center for Cell Death, School of Life Sciences & Biotechnology, Korea University, Seoul, Republic of Korea, [2]Division of Molecular Life Sciences, Ewha Womans University, Seoul, Republic of Korea, [3]School of Biological Sciences and Technology, Chonnam National University, Kwangju, Republic of Korea, [4]Department of Neuroscience, Ewha Womans University, Seoul, Republic of Korea, [5]Department of Animal Biotechnology, Konkuk University, Seoul, Republic of Korea, [6]Department of Pathology, Columbia University, College of Physicians and Surgeons, Seoul, Republic of Korea

The transmembrane protein Notch is cleaved by γ-secretase to yield an active form, Notch intracellular domain (Notch-IC), in response to the binding of ligands such as Jagged. Notch-IC contributes to the regulation of a variety of cellular events including cell fate determination during embryonic development as well as cell growth, differentiation and survival. We now show that the SAPK/JNK pathway was suppressed by overexpression of the murine Notch-IC (mNotch-IC). Ectopically expressed Numb, a negative regulator of Notch, blocked Notch1-IC-mediated inhibition of JNK activation. Ectopic expression of mNotch-IC in MEF$^{PS1(-/-)}$ cells suppressed $H_2O_2$-stimulated JNK activity and apoptosis. Notch1-IC also inhibited both JNK activation and apoptosis triggered by glucose deprivation. Taken together, these findings suggest that Notch1-IC functions as a negative regulator of signaling by the c-Jun N-terminal kinase pathway.

830

**Activation of JNK3 after Injury Induces Cytochrome C Release by Facilitating Pin1-Dependent Degradation of Mcl-1**

Q. Li,[1] C. Tep,[1] T. Yune,[1] X. Zhou,[2] K. Lu,[2] S. Yoon[1]; [1]Center for Molecular Neurobiology, Ohio State University, Columbus, OH, [2]Medicine, Cancer Biology Program, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA

Evidence has indicated that the JNK pathway plays a role in neuronal survival, but its mechanism remained unclear. We report that a selective increase in JNK3 activity after spinal cord injury is responsible for oligodendrocyte apoptosis. Upon activation, JNK3 induces cytochrome C release in part by facilitating degradation of Mcl-1 whose stability is normally maintained by Pin1. In the basal state, we found that Mcl-1 is phosphorylated at p-Thr163Pro, most likely by ERK, resulting in Pin1 recruitment. With injury, JNK3 phosphorylates Mcl-1 at Ser121, displacing Pin1, thereby facilitating degradation of Mcl-1 via ubiquitination. These data together suggest that JNK3 induces degradation of Mcl-1 by disrupting its association with Pin1. This report thus reveals a mechanism by which JNK3 regulates cytochrome C release, thereby regulates neuronal apoptosis under pathological conditions.

831

**Src Regulates Apoptosis in IEC-6 Cells by Activating STAT3 and Akt**

S. Bhattacharya, R. M. Ray, L. R. Johnson; Department of Physiology, University of Tennessee Health Science Center, Memphis, TN

Intestinal epithelial (IEC-6) cells are resistant to apoptosis following the inhibition of ornithine decarboxylase (ODC) and subsequent depletion of polyamines. The depletion of polyamines rapidly activates NF-κB and STAT3, which is responsible for the observed decrease in apoptosis. Since both NF-κB and STAT3 signaling pathways can be activated by Src kinase, we examined its role in the antiapoptotic response. Inhibition of ODC by α-difluoromethylornithine increased the activity of Src within 30 min. Activation was prevented by exogenous putrescine added to the DFMO containing medium. Inhibition of Src with PP2 and a dominant negative Src construct prevented the activation of Akt, JAK and STAT3. Spontaneous apoptosis was increased in cells in which Src was inhibited and the protective effect of polyamine depletion was lost. Our results suggest that the inhibition of ODC rapidly removes a small pool of available polyamines triggering the activation of Src which in turn activates Akt and JAK resulting in the translocation of NF-κB and STAT3 to the nucleus and the subsequent synthesis of antiapoptotic proteins.

**Studies on the Modulation of p53 and p21 Expression and the Enhancement of UVB Protection in Human Cells Through Stress-Free Hsp70 Induction by Artemia Extract**

C. Dal Farra, K. Cucumel, É. Bauza, N. Domloge; Vincience, Sophia antipolis, France

Corresponding studies of our own have demonstrated that Artemia extract 3% induces Hsp70 in human cells in a stress-free manner. Based on this data, we were interested in studying the protection from UVB insult offered by this stress-free induction of Hsp70, in cultured human fibroblasts and ex vivo skin organ culture. Cells were exposed to different UV doses after Hsp70 induction. Immunoblotting studies revealed that at low UVB doses, p53 and p21 were up-regulated more than in control cells, which suggests an enhancement in cell cycle arrest and in the action of the DNA repair pathway. These findings were confirmed by the comet assay which showed, no UVB-induced DNA degradation in Artemia-induced Hsp cells. Interestingly, at higher doses of UVB, our results were similar and showed that in Artemia-induced Hsp cells, both p53 and p21 levels were higher than in control cells. A significant decrease in cell damage and apoptosis was also seen in Artemia-induced Hsp cells at higher doses of UVB, which strongly suggests the action of the repair pathway rather than the apoptosis pathway, while most of the control cells showed the activation of p53-dependent apoptosis. In order to confirm this result, Hsp70 was induced in a similar manner in ex vivo skin prior to UVB exposure. In contrast to the extended signs of UV damage exhibited by the control skin, treated skin samples exhibited a great conservation of structure. Moreover, immunostaining of Langerhans cells revealed no signs of UV-induced immunosuppression in the Artemia-induced Hsp70 skin samples. These studies demonstrate that stress-free Hsp70 induction by Artemia extract is an approach that can be of great use in improving cell defense against UV stress.

**A Redox-based Mechanism of Growth Arrest and Induction of Apoptosis in Response to Cytotoxic Agents**

T. De Luca,[1] D. M. Morre,[2] D. Morre[1]; [1]Medicinal Chemistry and Molecular Pharmacology, Purdue University, West Lafayette, IN, [2]Foods and Nutrition, Purdue University, West Lafayette, IN

Our work has identified an NADH oxidase with protein disulfide-thiol interchange activity, designated tNOX, that is associated with unregulated growth of cancer cells and response to chemotherapeutic drugs. Substances that block tNOX include adriamycin, cis-platinum, the isoflavene phenoxodiol, the green tea catechin (-)-epigallocatechin-3-gallate and the vanilloid capsaicin. All result in growth arrest and induction of apoptosis accompanied by an increase in ceramide and a decrease in the prosurvival signaling molecule, sphingosine-1-phosphate (S1P). Implicated are activation of sphingomyelinase (SMase) to generate ceramide and inhibition of sphingosine kinase (SphK) to lower S1P. Our hypothesis is that one or more of the immediate products resulting from drug inhibition of tNOX would be responsible for SMase activation and SphK inhibition. When tNOX is inhibited, reduced coenzyme Q accumulates in the plasma membrane and NADH accumulates at the cytosolic plasma membrane surface. Treatment of recombinant neutral sphingomyelinase (nSMase) with reduced glutathione blocks activity, whereas NADH stimulates. If a normal function of the protein disulfide-thiol interchange activity of tNOX is to keep nSMase reduced, inhibition of tNOX would result in nSMase auto-oxidation and subsequent release from inhibition. These two changes, nSMase oxidation and NADH accumulation in the vicinity of the nSMase at the plasma membrane appear to be sufficient to account for nSMase activation and ceramide accumulation preceding growth arrest. In contrast, SphK, also located at the cytosolic side of the plasma membrane, is markedly inhibited by NADH in HeLa cells. Thus, inhibition of plasma membrane electron transport and attendant increased cytosolic NADH appear sufficient to initiate both growth arrest and apoptosis by cancer cell-specific cytotoxic agents via increased ceramide and the FAS-dependent apoptotic cascade.

**Lithium Blocks Ceramide- and Etopside-Induced Apoptosis via a Mechanism of Inhibiting Protein Phosphatase 2A Methylation and Activation**

C. Chen,[1] C. Lin,[1] C. Chiang,[2] M. Jan,[3] Y. Lin[1]; [1]Microbiology and Immunology, National Cheng Kung University Medical College, Tainan, Taiwan Republic of China, [2]Molecular Medicine, National Cheng Kung University Medical College, Tainan, Taiwan Republic of China, [3]Microbiology and Immunology, Chung-Shan Medical University, Taichung, Taiwan Republic of China

Lithium confers cell protection against stress and toxic stimuli. Although lithium inhibits a number of enzymes, the anti-apoptotic mechanisms of lithium remain unresolved. Here we report a novel role of lithium on the blockage of ceramide- and etoposide-induced apoptosis via inhibition of protein phosphatase 2A (PP2A) activity. During ceramide- and etoposide-induced apoptosis, lithium abolished the reduction of mitochondrial transmembrane potential and caspase-9 and -3 activation. PP2A inhibitor, okadaic acid (OA), caused an effect similar to that of lithium. Ceramide- and etoposide-activated caspase-2 and -8 was also blocked by lithium and OA. Lithium- and OA-mediated inhibitory effects were not observed after cytochrome *c* had been released, indicating that lithium and OA both acted upstream of mitochondria. Overexpression of PP2A resulted in caspase-2 activation, mitochondrial damage, and cell apoptosis that were inhibited by OA and lithium. Ceramide- and etoposide-induced Bcl-2 dephosphorylation at serine 70 was abrogated by lithium and OA. Furthermore, ceramide- and etoposide-induced PP2A activation involved methylation of PP2A C subunit, which lithium suppressed. Lithium caused dissociation of the PP2A B subunit from the PP2A core enzyme, whereas ceramide caused recruitment of the B subunit. Taken together, lithium exhibited an anti-apoptotic effect by inhibiting Bcl-2 dephosphorylation and caspase-2 activation upstream of mitochondrial damage, which involved a mechanism of downregulating PP2A methylation and PP2A activity.

835

**Glycogen Synthase Kinase-3β Modulates Ceramide-Induced T Cell Mitochondrial Apoptosis**

C. Lin,[1] C. Chen,[1,2] C. Chiang,[3] M. Jan,[4] Y. Lin[1]; [1]Department of Microbiology and Immunology, National Cheng Kung University Medical College, Tainan, Taiwan Republic of China, [2]Institute of Basic Medical Sciences, National Cheng Kung University Medical College, Tainan, Taiwan Republic of China, [3]Institute of Molecular Medicine, National Cheng Kung University Medical College, Tainan, Taiwan Republic of China, [4]Department of Microbiology and Immunology, Chung-Shan Medical University, Taichung, Taiwan Republic of China

The signaling of glycogen synthase kinase-3β (GSK-3β) has been implicated in stress-induced apoptosis. However, the pro-apoptotic role of GSK-3β remains unclear. Here we show the involvement of GSK-3β in ceramide-induced T cell mitochondrial apoptosis. First, ceramide-induced GSK-

3β activation by protein dephosphorylation at serine 9 was demonstrated. GSK-3β inhibitors including lithium chloride and SB216763 blocked the activation of GSK-3β and cell apoptosis caused by ceramide. Also, ceramide-induced caspase-2 and -8 activation, Bid cleavage, mitochondrial transmembrane potential reduction, cytochrome *c* release, and activation of caspase-9 and -3 were abolished by GSK-3β inactivation. Similarly, blockage on the ceramide-induced mitochondrial apoptosis was detected in cells with GSK-3β silencing using short interfering RNA technique. Furthermore, protein phosphatase 2A (PP2A)-regulated phosphatidylinositol-3-kinase (PI3K)/protein kinase B (PKB) signaling was involved in GSK-3β activation by ceramide. These findings indicate the dependence of GSK-3β regulation in ceramide-induced T cell mitochondrial apoptosis through PP2A- and PI3K/PKB-mediated signaling.

836

**A Novel Marker (PC-cholesterol Complex) for Foam Cell Apoptosis Can Be Induced by Hyperlipidemic Serum**

M. Mori,[1] H. Ogasawara,[1] A. Tanaka,[1] R. Soshi,[1] A. Isomura,[1] S. Kagiwada,[1] T. Asano,[1] H. Itabe,[2] T. Takano[1]; [1]Molecular Pathology, Fac. of Pharm.Sci. Teikyo University, Kanagawa, Japan, [2]Biochemistry, Fac. of Pharm.Sci. Showa University, Tokyo, Japan

**[Objective]** Phosphatidylcholine (PC)-cholesterol (FC) complex structures, a unique atheroma related antigen recognized by a novel monoclonal antibody ASH1a/256C. To elucidate the role of antigen in the development of atherosclerosis, the relationship among PC-FC complex, FC increase and apoptotic events in cultured foam cell were investigated. **[Method]** J774 cells incubated in the presence of hyperlipidemic sera or modified lipoproteins for 24 hr, then cultured up to 3-13 days. PC-FC complex were detected by immunofluorescent microscopy. UPR marker (CHOP, XBP-1) was detected by immunoblot analysis. **[Results & Discussion]** Using human or WHHL rabbit hyperlipidemic sera and J774 cells, we succeeded to express PC-FC complex on the surface of FC-rich lipid droplets as a foam cell death marker. PC-FC complex could be formed only when the cells were incubated with hyperlipidemic sera or AcLDL, not VLDL, LDL, moreover, VLDL enhances PC-FC complex formation by AcLDL; indeed, VLDL could not induce it by itself. Annexin-V positive cells were observed at day 3 induced by hyperlipidemic sera, whereas native LDL, HDL and VLDL failed to induce among FC-rich lipid droplets, PC-FC complex and Annexin-V binding structures. TUNEL positive cells were also observed in this foam cell culture at day 4 or later, whereas, no apoptotic cells were observed after treatment with U18666A in order to block cellular cholesterol transport. The UPR reaction marker, CHOP and XBP-1 were also detected. However, some HMG-CoA reductase inhibitors especially vascular-Statin (Simvastatin and Atorvastatin) were able to block the foam cell apoptosis not through FC induced ER stress. The hydrolysis and rearrangement of cellular cholesterol take place in foam cells to form the antigen; there were significantly relationship between the PC-FC complex formation and foam cell death.

837

**Electrapoptosis: Ultrashort Electrical Pulses Stimulate Skin Tumors to Self-Destruct**

R. Nuccitelli,[1] U. Pliquett,[1] W. Ford,[1] X. Chen,[1] J. Swanson,[1] S. J. Beebe,[2] J. F. Kolb,[1] K. H. Schoenbach[1]; [1]Center for Bioelectrics, Old Dominion University, Norfolk, VA, [2]Center for Pediatric Research, Eastern Virginia Medical School, Norfolk, VA

We have been using a new technology applying ultrashort electric pulses to treat melanoma skin tumors in mice. These pulses are so fast that charges on the tumor cell membranes do not have time to redistribute and screen out the imposed electric field from the cell interior (50 ns rise time). Therefore, these pulses penetrate into every cellular organelle for the duration of the pulse. These nanosecond pulses are very different from classical electroporation pulses that are much longer and have rise times in the microsecond domain, thereby preventing penetration of the electric field into the cell interior. Using nanosecond pulses with amplitudes greater than or equal to 2 volts/μm, a single treatment of 100 pulses causes the melanoma tumors to shrink by as much as 90% within about 10 days. Two targets of these pulses are the capillaries feeding the tumor and the tumor cell nuclei. Capillaries feeding the tumor become leaky immediately following the pulsed field application, disrupting the blood supply to the tumor. Red blood cells leak out and are dispersed around the tumor but blood flow to the tumor is not detectable by either transillumination or ultrasound Doppler imaging. In addition to the reduction in blood flow, tumor cell nuclei shrink by 40% and become pyknotic within an hour after pulsing. The threshold field for this response generates a two-volt difference across an organelle that is one μm in diameter, which is sufficient to cause organelle membrane breakdown or nanopore formation for the duration of the pulse. For a 100-pulse treatment, the total time that the tumor cells are exposed to this field is 0.03 ms, 100 times shorter than a single action potential in a nerve or muscle.

838

**17β-Estradiol and an ERα Agonist (PPT) Trigger Apoptosis in Human Adrenal Carcinoma Cells but an ERβ Agonist (DPN) Does Not**

J. W. Brown, L. M. Prieto, C. Perez-Stable, L. M. Fishman; Endocrinology Research, Department of Medicine, VA Medical Center, University of Miami Miller School of Medicine, Miami, FL

Earlier studies have shown that high-dose (10-5 M) 17β-estradiol (E) treatment has a G2/M blocking effect in SW-13 human adrenal carcinoma cultures and is a strong trigger of apoptosis. To examine the differential effects of estrogen α and β receptors (ER α and β) in this system, we incubated SW-13 cells with the specific ER α and β agonists (PPT [4,4',4''-(propyl-[1H]-pyrazole-1,3,5-triyl)-trisphenol] and DPN [2,3-bis(4-hydroxy-phenyl)-propionitrile], respectively; 10-5 M). We then used flow-cytometry to analyze the percentage of cells in various phases of the cell cycle (apoptosis, G1, S and G2/M). E treatment for 48-hrs increased apoptosis more than 5-fold (from 3.6 ± 0.5 % to 20 ± 2.2 % of cells; $p<0.01$). PPT had a similar effect, increasing apoptosis 6-fold to 22 ± 1.7 % ($p< 0.01$) but DPN caused no change (3.9 ± 0.8 % vs. 3.6 ± 0.5 %). E was found to block in G2/M, increasing it from 15 ± 0.4 % to 21 ± 1.0 % ($p<0.01$), but neither PPT nor DPN had any effect. Both E and PPT decreased the percentage of cells in G1 (from 59 ± 1.4 % for control to 34 ± 2.3 % for E and 40 ± 2.0 % for PPT; $p< 0.01$), while DPN had no effect. Neither E, PPT nor DPN affected cells in S phase. These studies suggest that induction of apoptosis by E in SW-13 cultures is likely mediated by the ER α receptor. Experimental results also imply that the G2/M blocking effect of E is not due to either ER α or β mechanisms. These studies were supported by the U.S. Department of Veterans Affairs and the South Florida Veterans Affairs Foundation for Research and Education.

**Over Expression of Human ClpP Reduces AIF Levels and Inhibits Cisplatin-Induced Apoptosis in Huh4 Cells**

Y. Zhang,[1] V. Barr,[2] M. R. Maurizi[1]; [1]Lab of Cell Biology, NCI/NIH, Bethesda, MD, [2]Lab of Cell Molecular Biology, NCI/NIH, Bethesda, MD

ClpXP is a bipartite chaperone/protease machine that catalyzes ATP-dependent protein unfolding and degradation in bacteria and in subcellular

compartments of eukaryotes. The biological functions of the ClpXP in mammalian cells have not been characterized. We investigated the effects of human ClpP (hClpP) over expression on cisplatin-induced apoptosis in the human hepatoma cell line, huh-4. We found that over expression of hClpP in huh-4 cells inhibits cisplatin-induced apoptosis. High levels of hClpP caused a 50-55% reduction in the number of cells undergoing apoptosis between 16-48 h following cisplatin treatment. A corresponding decrease in amounts of activated PARP and caspases 3, 7, and 9 was observed in the cells over expressing hClpP. Interestingly, the basal level of apoptosis inducing factor (AIF) was significantly reduced in hClpP cells prior to cisplatin treatment. Consequently, the release of AIF from mitochondria to the cytosol following cisplatin treatment was much lower in cells over expressing hClpP. High-level expression of hClpP did not affect the total amount or release of cytochrome-c, Smac, or HTRA2/OMI. Taken together, these results suggest that hClpP exerts its effect on cisplatin-induced apoptosis by modulating the intracellular levels of AIF possibly by reducing AIF synthesis or increasing its degradation. Our results indicate that the apoptotic response in cells will be affected by conditions that increase or decrease the intracellular levels of pro- or anti-apoptotic proteins. Current work is focused on the mechanism of the hClpP-mediated effects on AIF expression, which might provide insight into the biological functions of ClpXP in mammalian cells.

**Shiga Toxin 1 is Internalized and Causes Apoptosis in Gb3-negative Intestinal Epithelial Cells**

M. S. Laiko,[1] M. Donowitz,[1] A. Kane,[2] O. Kovbasnjuk[1]; [1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]GRASP Center, Tufts New England Medical Center, Boston, MA

The foodborne illnesses caused by the Shiga toxin 1 (Stx1) producing enterohemorrhagic *Escherichia coli* (EHEC) include bloody diarrhea, hemolytic uremic syndrome (HUS) and encephalopathy. The current view is that Stx1 binding to its receptor the glycosphingolipid $Gb_3$ is the initial step in a cascade leading to HUS. However, it has recently been shown that human colonic epithelium does not express Gb3. The goal of our research was to characterize the mechanisms of interaction of Stx1 and its recombinant B-subunit (Stx1B) with Gb3-negative intestinal epithelial T-84 cells and compared it to the Stx1/Stx1B effects on Gb3-positive Caco-2 cells. Confocal microscopy shows that Stx1B-Alexa 488 interacts with both cell types. In Caco-2 cells Stx1B is taken up through the retrograde pathway into the Golgi/ER. In T84 cells Stx1B appears in intracellular vesicles that co-localize with 40K dextran, but not in Golgi/ER. Western immunoblotting shows that Stx1 and Stx1B induce apoptosis in both CaCo-2 and T-84 cells. However, the apoptotic mechanisms triggered by holotoxin vs. B-subunit are different. Exposure of CaCo-2 and T-84 cells to Stx1 for 72 hours increased intracytosolic cytochrome C and AIF, activated caspase-3 with PARP cleavage. In contrast, Stx1B didn't induce caspase-3 cleavage in T-84 or CaCo-2 cells. It released mitochondrial cytochrome C and activated caspase-2 in both cell types. We conclude that Stx1/Stx1B is internalized by Gb3-free intestinal epithelial cells, which triggers the apoptosis. This shows the presence of receptor-independent uptake of Stx1 that may be important for intestinal and systemic disease. .

**What Effects do Household Chemicals, Permethrin and Propylene Glycol, Have on U937 Cells and A549 Cells?**

T. N. Ezell,[1] E. Benjamin,[2] Y. Hijji,[2] L. Taylor[1]; [1]Biology, Morgan State University, Baltimore, MD, [2]Chemistry, Morgan State University, Baltimore, MD

Multiple chemical sensitivity (MCS) syndrome occurs with low-level chemical exposure. People are continuously exposed to natural and synthetic chemicals. Many of these chemicals have the ability to cause acute and chronic inflammatory responses. Studies have estimated that approximately 64,000 people in the United States die prematurely from heart and lung disease every year due to pollution and chemical exposures. Permethrin (PTN) and propylene glycol (PG) are synthetic chemicals that are found in many household products such as cosmetics, deodorants, lotions, insect foggers, flea dips, garden and turf products, mosquito sprays, termite treatments, and agricultural products. Previous studies have determined that PG and PTN at low doses decrease immune cell recognition and responses to foreign antigens. At high doses PTN is also know to cause inflammation and necrosis. The present study explores the mechanism of action of PTN and PG by measuring alterations in cellular growth, viability, and toxicity. U937 and A549 cells were cultured in 24-well plates at 0.5-1 X $10^5$ cells/well for 2 hours. The cells were then exposed to 0 - 10 µg/ml of PG and/or 0 - 0.5 ng/ml of PTN. The cultures were incubated for 24, 48, and 72 hrs at 37$^o$C and 5% $CO_2$. At each time point, the cells were observed, counted, stained with Calcein and Ethidium Homodimer-1 and photographed using fluorescence and light microscopy. Preliminary data suggest that U937 cells and A549 cells exposed to PTN, PG and PTN + PG exhibited a dose dependent decrease in cellular growth.G12RR017581P, DOE grant DE-FG0T-03ER63580

**Apoptosis Regulates Notochord Development in *Xenopus laevis* Embryos**

M. A. Malikova, M. Van Stry, K. Symes; Department of Biochemistry, Boston University School of Medicine, Boston, MA

The notochord is a defining characteristic of the chordate embryo. It develops at the midline during gastrulation and persists as a long, flexible rod that underlies the neural tube and extends through most of the length of the embryo. The notochord plays crucial roles throughout embryonic development, such as inducing ectoderm, endoderm, and mesoderm derivatives in the early embryo, structurally, as a primitive skeleton, and ultimately forming the intervertebral discs of the spine. Our recent evidence in *Xenopus* suggests that notochord development is regulated, at least in part by apoptosis. We find that TUNEL positive cells appear in the notochord beginning at stage 18 and that the number of dying cells increases with developmental stage. In addition, these apoptotic cells are distributed in an anterior to posterior pattern that is correlated with notochord extension through vacuolization. We do not find any TUNEL positive cells in the somitic mesoderm at the stages examined (stages 15-25). Inhibition of notochord cell death by overexpression of the anti-apoptotic factor, Bcl-2, causes an increase in the length-to-width ratio of mesoderm explants and the notochord is approximately double the length of that in control explants. In intact embryos, Bcl-2 overexpression causes axial defects such as spina bifida. The length of the notochord in these embryos, however, is not increased, but the notochord is severely buckled. This buckling also appears in an anterior to posterior pattern with developmental stage. We propose that during normal development, to coordinate the extension rate of the notochord during vacuolization with surrounding tissues such as the somites and neural tube, cells are removed from the notochord by apoptosis.

**Slug (Snail2) Is an Antiapoptotic Factor during Tubulogenesis of MDCK Cells**

P. Leroy, K. E. Mostov; Anatomy, UCSF, San Francisco, CA

Slug (Snail2), a member of the Snail family of transcription factors, has been described as a key regulator of epithelial-mesenchymal transition (EMT) and a repressor of E-cadherin. Slug has also been involved in processes that do not required a full EMT and in the protection of cells from cell death. Here, we present evidences that Slug is induced during Hepatocyte Growth Factor (HGF)-induced tubulogenesis of Madin-Darby Canine Kidney (MDCK) cells and that it has an antiapoptotic role during this process. Tubulogenesis is a process involved in the formation and maintenance of diverse organs, during which cells undergo important morphogenetic modifications requiring tight control. Epithelial MDCK cells are able to form tubules in a 3-dimensional culture system. MDCK cells seeded in a collagen gel form cysts which are spherical monolayers of cells enclosing a central lumen. Within 24hrs of HGF treatment, the cysts form extensions and chains and after 2 to 3 days, tubules. The first phase of extension and chain is described as a partial EMT (p-EMT) during which the cells lose their epithelial polarity but not their epithelial markers. We show that Slug is upregulated by HGF during the p-EMT phase of tubulogenesis and that its expression decreases during tubule formation. The upregulation of Slug is not accompanied by a down-regulation of E-cadherin expression. Both the MEK inhibitor U0126 and the PI3K inhibitor LY294002 block Slug upregulation independently. Using an inducible antisense Slug construct to block the expression of Slug, we found that Slug knockdown does not impair the initial phase of extension but leads to apoptosis of the cells that have undergo extension. This work reports for the first time the involvement of Slug during MDCK tubulogenesis and links its role with an EMT-dependent process and apoptosis.

844

**Differential Apoptosis Regulation Following Changes in Bcl-2's Sub-cellular Localization**

B. P. Portier, G. Taglialatela; University of Texas Medical Branch, Galveston, TX

B-cell leukemia/lymphoma 2 (Bcl-2) is the prototypical member of a large family of proteins that function as modulators of apoptosis. While Bcl-2 functions as an anti-apoptotic protein when localized at the mitochondria its function at other organelles (ER and nucleus) is largely unreported. Here we used an *in vitro* model to investigate nuclear localized Bcl-2's role in promoting/inhibiting apoptosis. Our results show rapid Bcl-2 expression (via transient transfection) leads to increased nuclear localized Bcl-2 in PC12 cells. However, nuclear localization is lost following long term (stable) Bcl-2 expression. Using Invitrogen's pGeneSwitch inducible expression system to express Bcl-2/YFP (a Bcl-2 yellow fluorescent fusion protein) paired with flow cytometry, we are able to specifically investigate nuclear associated Bcl-2's role in apoptosis. Using flow cytometry on whole cells and isolated nuclei following induced Bcl-2/YFP expression allows direct and simultaneous measurement of apoptotic status, Bcl-2 expression and nuclear localization. It is our hypothesis that high Bcl-2 expression leads to nuclear association and if prolonged in time, apoptosis. In addition, co-expression of FKBP38 can effectively prevent Bcl-2 from associating with the nuclear compartment. These studies should further our understanding of Bcl-2's function at different sub-cellular locations. These data also suggest a novel involvement of Bcl-2 functioning as a pro-apoptotic protein, a characteristic that could lead to new strategies aimed at blocking Bcl-2 induced apoptosis thereby protecting cells undergoing apoptotic stress. **Identification and Characterization of New Drosophila Mitotic Genes by Co-expression Analysis and RNA-mediated Interference**

M. P. Somma,[1] E. Bucciarelli,[1] V. Naim,[1] F. Ceprani,[1] V. De Arcangelis,[1] R. Piergentili,[1] A. Palena,[1] G. Belloni,[1] L. Ciapponi,[1] R. Petrucci,[1] G. Cenci,[1] M. G. Giansanti,[1] F. Vernì,[1] C. Pellacani,[1] B. Fasulo,[1] F. Di Cunto,[2] M. Goldberg,[3] M. Gatti[1]; [1]Dip. Genetica e Biologia Molecolare, Istituto di Biologia e Patologia Molecolari del CNR, Rome, Italy, [2]Dipartimento di Genetica, Biologia e Biochimica, Università di Torino, Torino, Italy, [3]Department of Molecular Biology and Genetics, Cornell University,, Ithaca, 14853-2703, NY

Based on the principle that genes involved in the same biological process tend to be significantly co-expressed, we exploited the extant microarray data to order the Drosophila genes according to their co-expression with known mitotic genes. We verified that the first 1000 genes of our co-expression list include more than one half of the known mitotic functions. With the aim of identifying novel genes involved in mitotic cell division, we performed RNAi experiments to inactivate each of these 1000 genes. Drosophila S2 cells were treated with double stranded RNA for three days and then analyzed for the normality of the chromosomes and the mitotic spindle. This screen led to identification of over 70 genes that have not previously been implicated in mitosis. Ablation of these genes resulted in a variety of mitotic phenotypes: (a) chromosome breakage, (b) abnormal chromosome condensation, (c) precocious sister chromatid separation, (d) defective spindle assembly, (e) metaphase arrest, (f) abnormal chromosome segregation, and (g) failures in cytokinesis. Most of the Drosophila genes identified in our screen have homologues in other eukaryotes including humans, thus providing a putative function for a fraction of the human genome.

846

**Regulation of Klp61F by *Drosophila* Wee1**

K. Garcia,[1] J. Stumpff,[2] T. Su[1]; [1]Molecular, Cellular, and Developmental Biology, University of Colorado, Boulder, CO, [2]Physiology and Biophysics, University of Washington, Seattle, WA

Wee1 tyrosine kinases act during interphase to phosphorylate and inactivate cyclin dependent kinase1 (Cdk1), thereby preventing entry into mitosis. Our observations, however, indicate that *Drosophila* Wee1 (dWee1) also plays a role in mitotic spindle function that is independent of its role in Cdk1 regulation at mitotic entry. We find that *dwee1* mutant embryos display disrupted mid-spindles, microtubule spurs extending from the mitotic spindle, and collisions between adjacent spindles. In addition, we found that dWee1 physically interacts with Klp61F, the *Drosophila* homolog of the BimC/Eg5 kinesin that is involved in mitotic spindle organization and centrosome separation. Klp61F displays decreased tyrosine phosphorylation in extracts from *dwee1* mutant embryos, and dWee1 directly phosphorylates Klp61F on tyrosine residues *in vitro*. Mass spectrometric analyses identified four phosphorylated peptides in Klp61F after incubation with dWee1. Three peptides fall within the motor domain and the remaining peptide is part of the BimC box located in the tail domain. Since these domains are important for Klp61F function, our objective is to show that dWee1 has a role in mitotic spindle function by regulating Klp61F via phosphorylation. Our future plans include the

determination of the functional importance of *dwee1*-dependent phosphorylation on Klp61F.

847

**The Kinesin-6, PavKLP, Mediates Spindle-Cortical Interactions in *Drosophila* Embryos**

P. Sommi, M. Kwon, S. Morale-Mulia, D. Cheerambathur, A. Mogilner, J. M. Scholey; Center for Genetics and Development, University of California, Davis, CA

The morphogenesis of the mitotic spindle is a dynamic process that is known to be driven by microtubules (MTs) and associated molecular motors but recent studies suggest that cortical organization also plays a key role in this process. Here we examined the contribution of the kinesin-6 family member, PavKLP to mitotic spindle and cortical dynamics in *Drosophila* embryos. Using a newly-generated anti-PavKLP antibody for hydrodynamic studies, we determined that PavKLP behaves as a dimer in embryonic extracts. Immunofluorescence revealed that PavKLP associates with puncta on mitotic spindles and on the cortex. Cortical PavKLP punctae specifically co-localize with actin at the mitotic furrows from interphase through anaphase and the functional disruption of PavKLP by antibody microinjection causes defects in spindle pole separation, central spindle organization and the formation and ingression of actin furrows. In addition we tested the hypothesis that PavKLP may contribute to furrow dynamics by driving vesicle transport. Using immunofluorescence, we observed that PavKLP co-localizes with Golgi vesicles localized at the embryonic cortex and in aster-like MT structures. In S2 cells, where PavKLP depletion by RNAi leads to defects in both central spindle organization and cytokinesis, Golgi and PavKLP co-localization was confirmed from interphase through cytokinesis. Based on the disorganization of actin following PavKLP inhibition and the co-localization of PavKLP and Golgi vesicles, we propose that PavKLP mediates spindle-cortical interactions by transporting vesicles along astral MTs to the cortex and is thus required for the proper organization of cortical furrows during mitosis.

848

**Role of *Drosophila* Pericentrin-like Protein (D-PLP) in Centrosome Maturation**

E. P. Lucas, N. Peel, T. Barros, J. W. Raff; Wellcome Trust/CR-UK Gurdon Institute, Cambridge, United Kingdom

The *Drosophila* Pericentrin-like protein (D-PLP) is the only recognisable protein with a Pericentrin-AKAP450 centrosomal targeting (PACT) domain in flies. D-PLP is a large coiled-coil protein that is concentrated in both the centrioles and the PCM throughout the cell cycle. Initial studies in larval brain cells suggested that this protein was required for the efficient centrosomal recruitment of γ-tubulin and of all the PCM components tested (CNN, D-TACC, Msps, CP190 and CP60), as their centrosomal localisation was strongly disrupted in *d-plp* mutant cells. Surprisingly, however, all the PCM components tested could eventually be recruited to centrosomes in at least some *d-plp* mutant cells, and mitosis was not dramatically perturbed. Therefore, in order to further study the potential role of D-PLP in recruiting and tethering γ-tubulin and other PCM components to the centrosome, we are currently investigating how the PCM components can be recruited to the centrosomes in the absence of D-PLP. Our data from *d-plp* germline clone analysis revealed that D-PLP is not required for the recruitment of PCM components to the centrosomes, but instead, it seems to play an important role in maintaining the structural integrity of the PCM. In addition, it also suggests that there is some other force that holds the PCM together in the absence of D-PLP and microtubules. Moreover, we are also investigating whether there is a functional redundant mechanism that can maintain the structural integrity of the centrosomes whenever D-PLP is absent.

**Chromokinesins Affect the Flux Rate of Mitotic Spindle Microtubules in *Drosophila* S2 Cells**

D. W. Buster, D. J. Sharp; Physiology and Biophysics, Albert Einstein College of Medicine, Bronx, NY

Chromokinesins, a family of chromosome-associated microtubule motors, are potential generators of aneuploidy since they are believed to participate in spindle morphogenesis and chromosome movements during mitosis. Previously, we have reported that knock-down of some chromokinesins in cultured *Drosophila* S2 cells leads to a significant increase in chromatid number per cell, though not all chromokinesins have identical affects, suggesting that they perform different functions in chromosome segregation. In addition, some chromokinesins significantly increase the mitotic index and the frequency of multi-nucleation. To examine possible mechanisms that could require chromokinesin activity, we are testing the hypothesis that chromokinesins affect the flux rate of spindle microtubules. Single (or combinations of) chromokinesins are knocked-down by RNA interference in S2 cells expressing a low level of GFP-tubulin, and the flux rates of the mitotic spindle microtubules are measured by fluorsecent speckle microscopy. Interestingly, our results suggest that RNAi of different chromokinesins can have opposite affects on flux rates. RNAi of the chromokinesin, KLP38B, increases the flux rate, while RNAi of a putative chromokinesin, KLP88A, produces a trend of flux rate reduction. Therefore, chromokinesins can impact flux rates, but their affects are not identical. Unexpectedly, some chromokinesins (eg, KLP38B, nod) might impose a drag on fluxing microtubules in vivo.

850

**The CLASP, Mast, and Microtubule-depolymerizing Kinesins Interact Functionally to Regulate Spindle Length and Flux in *Drosophila* S2 Cells**

D. W. Buster, D. J. Sharp; Physiology and Biophysics, Albert Einstein College of Medicine, Bronx, NY

Proper mitotic spindle formation and chromosome segregation in higher eukaryotes require that spindle microtubules flux at normal rates. Recently, two spindle-associated proteins, KLP10A and Mast/Orbit, were found to strongly impact flux rates in different systems. To study the functional interplay of these flux generators, we used RNA interference (RNAi) to knock-down these proteins individually or in combination. The short spindle phenotype generated by Mast RNAi was rescued by co-RNAi of KLP10A, but was also partly rescued by co-RNAi of either KLP59C or KLP67A, two centromeric kinesins. Flux rates of spindle microtubules were significantly decreased by either KLP10A or Mast RNAi, but the Mast RNAi affect could be partly rescued by co-RNAi of KLP59C or KLP67A, but not KLP10A. Therefore, KLP10A and Mast have balanced but opposing effects on spindle lengths, but both activities are required for normal flux rates.

851

**Unique Requirement for MCAK in Microtubule Disassembly During Spindle Morphogenesis**

R. Ohi,[1] M. L. Coughlin,[1] T. J. Mitchison[1,2]; [1]Systems Biology, Harvard Medical School, Boston, MA, [2]Institute for Chemistry and Cell Biology,

Boston, MA
Bipolar meiotic spindle assembly in *Xenopus* extracts depends on microtubule (MT) depolymerization by the type 13 kinesin MCAK and its regulation by the Aurora B kinase. This mechanism stimulates chromatin-driven MT assembly and is complementary to the Ran pathway, which activates MT assembly promoting factors. KIF2 is a second Kinesin 13 present in this system suggesting complexity in MT depolymerization control during chromosome segregation. To understand tasks unique to MCAK and KIF2, as well as their potential functional redundancies, we first established using quantitative microtubule depolymerization assays that MCAK and KIF2 are comparatively potent microtubule destabilizing enzymes *in vitro.* KIF2 is also similar to MCAK in that its MT depolymerizing activity is inhibited by Aurora B-dependent phosphorylation. Despite these similarities, we find that perturbation or removal of KIF2 from *Xenopus* egg extracts has no consequence on spindle assembly, indicating that MCAK is uniquely required for this process. Notably, KIF2 is ~4-fold less abundant than MCAK in *Xenopus* extracts, suggesting that the dominant role of MCAK in spindle assembly may simply reflect its greater protein concentration. This is not the case, however, as replacement of MCAK with KIF2 results in spindle assembly failure and large cytoplasmic radial MT asters. We speculate that KIF2 is only critical for MT depolymerization control at inner centromeres, whereas MCAK is required both for cytoplasmic MT dynamics regulation as well as MT dynamics regulation within the meiotic spindle.

852

**Analysis of *Xenopus* Xorbit/CLASP in Spindle Assembly and Function**

E. Hannak, R. Heald; MCB, UC Berkeley, Berkeley, CA
A family of non-motor microtubule binding proteins, Orbit/MAST/CLASP has emerged as an important player during mitosis, functioning in chromosome congression and maintenance of spindle bipolarity in *Drosophila* and mammalian cells. Here, we used meiotic egg extracts to gain insight into the role of the *Xenopus laevis* homologue, Xorbit, in spindle assembly and function. By immunofluorescence, Xorbit localized along the length of spindle microtubules, concentrating at kinetochores on metaphase spindles and shifting to the spindle midzone in late anaphase. Immunodepletion of Xorbit or its inhibition by addition of a dominant negative fragment, GST-CT, prevented chromosome alignment at the metaphase plate and resulted in aberrant microtubule structures including monopolar and short spindles. We have identified a biochemical interaction between Xorbit and the kinetochore-associated kinesin CENP-E, which may contribute to the role of Xorbit in chromosome congression. Xorbit-depleted extracts failed to form bipolar structures around chromatin-coated beads in the absence of centrosomes and kinetochores, indicating that it also plays an important role in chromatin-driven microtubule polymerization. The stabilizing role of Xorbit was most apparent during anaphase, when spindle microtubules depolymerized rapidly upon Xorbit inhibition. These data reveal a crucial role for Xorbit in stabilizing both kinetochore and non-kinetochore microtubules. We propose that Xorbit tethers dynamic microtubule plus ends to kinetochores and chromatin, providing a stabilizing activity essential for spindle assembly and chromosome segregation.

853

**Dynein Light Intermediate Chain 1 Has a Unique Function in the Spindle Assembly Checkpoint**

T. L. Wadzinski, S. J. Doxsey; Program in Molecular Medicine, University of Massachusetts Medical School, Worcester, MA
The spindle assembly checkpoint (SAC) ensures that a cell has bi-oriented chromosomes that accurately divide between daughter cells. This checkpoint has two components. First, Mad2 localizes to kinetochores until adequate microtubule attachment is achieved. Second, Bub1 and BubR1 localize to kinetochores until there is adequate tension across them. Dynein is a kinetochore associated protein complex that induces a metaphase arrest by activating the SAC when disrupted. This complex is implicated in moving Mad2 from kinetochores and generating tension across kinetochores. Light intermediate chain 1 (LIC1) is a poorly understood component of dynein. Here we show that RNAi-mediated depletion of hLIC1 in human cells results in a metaphase arrest; timing of the other mitotic phases is unaltered. This arrest is not due to a general dynein disruption because in hLIC1 depleted cells dynein functions normally in golgi and spindle organization, dynein localizes normally to kinetochores and spindle poles, and the dynein complex is intact. In fact hLIC1 depleted metaphase cells have fully congressed chromosomes that appear to be under tension as Bub1 and BubR1 are gone from kinetochores. Mad2 localization remains unclear however Mad2 depletion allows hLIC1 depleted cells to go through mitosis, implicating the SAC in this arrest. Cdc2 phosphorylation and regulation of LIC1 in mitosis has been reported previously. Interestingly LIC1 phosphorylation status plays a role in this checkpoint because expressing phosphomemetic forms of rat LIC1 allow hLIC1 depleted cells to get through the checkpoint whereas pseudo-unphosphorylated rLIC1 does not relieve the checkpoint. We are using this unique phosphorylation status in a proteomic approach to identify interacting proteins involved in this checkpoint. We propose that LIC1 links Mad2 to dynein and without LIC1, dynein cannot move Mad2 off the kinetochore to relieve the SAC.

854

**Rapid Microtubule Dynamics in *Drosophil*a Embryonic Mitotic Spindles**

D. Cheerambathur, G. Civelekoglu-Scholey, I. Brust-Mascher, P. Sommi, A. Mogilner, J. M. Scholey; Center for Genetics and Development, University of California, Davis, Davis, CA
Spindle microtubules are highly dynamic and are measured to turnover with characteristic times of the order of 10 to 100s of seconds in most organisms. Here we used Fluorescence Recovery After Photobleaching (FRAP) of GFP-tubulin in *Drosophila* embryos to observe microtubule dynamics within the mitotic spindle and show that the turn-over rate of MTs in *Drosophila* spindles is very high, with a half time for recovery of 5-7 sec (Brust-Mascher et al. 2004). Our recent study shows, surprisingly, that this rapid recovery half time is the same irrespective of the size and the region of bleach zone and regardless of the mitotic stage when spindle bleaching is performed, from metaphase till telophase. This fast turn over rate is slowed down by the inhibition of *Drosophila* EB1, a protein that has been shown to affect dynamic instability parameters of MTs. Currently we are investigating several mutants of other proteins which functions as dynamic instability regulators to test their effect on the recovery rate. We are complementing these studies with computer simulations based on a previously developed model (Brust-Mascher et al. 2004) to investigate the distributions of MT plus and minus ends and MT lengths that could give rise to such rapid recovery rates and match the change in the recovery rate in response to drugs that alter MT dynamics.

855

## Integrin Signaling and Control of Spindle Orientation

F. Toyoshima, E. Nishida; Cell and Developmental Biology, Kyoto University, Kyoto, Japan

Alignment of the mitotic spindle with a predetermined axis occurs in many types of polarized cells such as cells in epithelial tissues, but it has been unknown whether there is a mechanism regulating spindle orientation in non-polarized cells. We found that integrin-dependent cell adhesion to the substrate orientates the mitotic spindle of non-polarized cultured cells, such as HeLa cells, parallel to the substrate plane in a cytoskeleton-dependent manner. The spindle is properly oriented in cells plated on fibronectin or collagen, but not in cells on poly-L-lysine. Moreover, the spindle is misoriented in cells treated with the RGD peptide or anti-integrin antibody, indicating requirement of integrin-mediated cell adhesion for this mechanism. This integrin-dependent spindle orientation is independent of gravitation or cell-cell adhesion, but requires actin cytoskeleton, astral microtubules, microtubule plus-end-tracking protein EB1, and myosin X. We are now analyzing roles for membrane components, which are known to be involved in integrin signaling, in the control of spindle orientation.

856

## Mechanism Controlling Perpendicular Alignment of the Spindle to the Axis of Cell Division in Fission Yeast

Y. Gachet,[1] C. Reyes,[1] S. Goldstone,[1] J. Hyams,[2] S. Tournier[1]; [1]LBCMCP-CNRS UMR5088, Institut d'Exploration Fonctionelle des Génomes (IFR109), Université Paul Sabatier, Toulouse, France, [2]Institute of Molecular Biosciences, Massey University, Palmerston North, New Zealand

In animal cells, the mitotic spindle is aligned perpendicular to the axis of cell division. This ensures that sister chromatids are separated to opposite sides of the cytokinetic actomyosin ring (CAR). We show that, in fission yeast, spindle rotation is dependent on the interaction of astral microtubules with the cortical actin cytoskeleton. Interaction initially occurs with a region surrounding the nucleus, which we term the astral microtubule interaction zone (AMIZ). Simultaneous contact of astral microtubules from both poles with the AMIZ directs spindle rotation and this requires both actin and two type V myosins, Myo51 and Myo52. Astral microtubules from one pole only then contact the CAR, which is located at the centre of the AMIZ. Finally, we show that the position of the mitotic spindle is monitored by a checkpoint that regulates the timing of sister chromatid separation. We find that whereas sister kinetochore pairs normally congress to the spindle midzone before anaphase onset, this congression is disrupted when astral microtubule contact with the actin cytoskeleton is disturbed. By analyzing the timing of kinetochore separation, we find that this anaphase delay requires the Bub3, Mad3, and Bub1 but not the Mad1 or Mad2 spindle assembly checkpoint proteins. In agreement with this, we find that Bub1 remains associated with kinetochores when spindles are mispositioned. These data indicate that, in fission yeast, astral microtubule contact with the medial cell cortex is monitored by a subset of spindle assembly checkpoint proteins.

857

## INT6 and Moe1 Interact with Cdc48 to Regulate Mitotic Progression in *Schizosaccharomyces pombe*

J. H. Otero,[1] E. C. Chang[2]; [1]Interdepartmental Program in Cell and Molecular Biology, Baylor College of Medicine, Houston, TX, [2]Department of Molecular and Cellular Biology Breast Cancer Center, Baylor College of Medicine, Houston, TX

*INT6* is a key gene involved in the formation of breast cancer, as it is a frequent site of integration by the mouse mammary tumor virus. To better understand the functions of Int6, we have characterized an Int6 homolog (Yin6) in the fission yeast *Schizosaccharomyces pombe.* Our data support a model in which Yin6 regulates many mitotic functions, including spindle formation, chromosome segregation, and mitotic exit by controlling the localization and assembly of subunits of the proteasome. In my study, I plan to further characterize Yin6 by focusing on a evolutionarily conserved protein, Moe1, to which Yin6 binds directly. In two-hybrid screens, we have isolated several proteins that are involved in the endoplasmic reticulum associated degradation (ERAD) pathway as Moe1-binding proteins. Of these, we are particularly interested in Cdc48, which like Yin6 and Moe1, regulates proteasome mediated protein degradation and spindle dynamics. In support of the two-hybrid data, our biochemical data show that Cdc48 binds Yin6 and Moe1 in *S. pombe* cells. Furthermore, genetic analyses show that mutations affecting *cdc48,* together with mutations inactivating either *yin6* or *moe1,* acts synergistically to create a severe mitotic defect. These observations support the hypothesis that the Yin6-Moe1 complex can interact with Cdc48 to regulate mitosis and whether their actions converge upon proteolysis regulation is currently under investigation.

858

## Correlating *HZW10* Functional Domains to Mitotic Checkpoint Function

J. K. Famulski,[1] G. K. Chan[1,2]; [1]Oncology, University of Alberta, Edmonton, AB, Canada, [2]Experimental Oncology, Cross Cancer Institute, Edmonton, AB, Canada

Human *Zeste White* (hZW10) is an essential mitotic checkpoint protein involved in ensuring proper chromosome segregation during mitosis (Chan *et al.* 2000). hZW10 localizes to the kinetochores during prometaphase where it forms a conserved complex with *Rough Deal* (hRod) (Scaerou *et al.* 2001). Recruitment of hZW10 to the kinetochore has been shown to be hZwint dependent (Wang *et al* 2004). The hZW10/hRod complex is responsible for the recruitment of the microtubule motor, dynein/dynactin and checkpoint proteins Mad1 and Mad2 to the kinetochore (Chan *et al.* 2000; Kopps *et al.* 2005). We have performed a structure function study of hZW10 to determine its function(s) within the mitotic checkpoint. Using random 5 amino acid insertion mutagenesis, deletions and truncations, we have generated mutants of hZW10 with disrupted functional domains. So far we have identified mutants with disrupted kinetochore localization, dynamitin and hZwint interaction domains as assayed by immunofluorescence and yeast two hybrid analysis. Contrary to published results, we found that the C-terminus of hZW10 is required for kinetochore localization but dispensable for hZwint interaction. Furthermore, a N-terminal 52 amino acid deletion in hZW10 prevents hZwint interaction but still retains kinetochore localization. This result suggests that hZwint is necessary but not sufficient for hZW10 kinetochore localization. Disruption of hZW10-dynamitin interaction has no effect on hZW10 kinetochore localization. Dimerization of hZW10 might be a possible explanation for our results. We are examining the hZW10 mutants for dominant negative phenotypes *in vivo*. Mitotic checkpoint function is assayed by monitoring mitotic escape in the presence of vinblastine. We are examining the disruption of kinetochore microtubule attachment by immunofluorescence. We are also examining the changes in hZW10 dynamics at kinetochores by Fluorescence Recovery After Photobleaching (FRAP). Our assays will correlate distinct functional domains of hZW10 to mitotic checkpoint function.

859

**The Chromosomal Passenger Complex Regulates HP1 Localization by Phosphorylation of Histone H3 Serine 10**

B. Tseng, H. Funabiki; Laboratory of Chromosome and Cell Biology, The Rockefeller University, New York, NY

The functional significance of histone H3 serine 10 phosphorylation during M phase is unclear. Fischle, Wang, and Allis have proposed the binary switch hypothesis, which states that phosphorylation of histone H3 serine 10 inhibits the binding of heterochromatin protein 1 (HP1) to the adjacent trimethylated lysine 9 of histone H3 (H3K9me3)[1]. Since Aurora B, a member of the chromosomal passenger complex (CPC), phosphorylates histone H3 serine 10, we examined whether this complex regulates the chromosomal binding of HP1 via this phosphorylation using *Xenopus* egg extracts. We found that although depletion of the CPC did not affect H3K9me3 levels, both endogenous xHP1α and exogenous xHP1α, β, and γ bound better to metaphase chromosomes assembled in extract depleted of the CPC than in control extract. The dependence of this enhanced association on H3K9me3 was verified by two methods. First, alanine mutation in xHP1α at tryptophan 57, which is important for the binding to H3K9me, diminished the chromosomal binding of xHP1α in the absence of the CPC. Second, the addition of an H3K9me3 peptide, but not an unmodified H3 peptide, to CPC-depleted extracts reduced the chromosomal association of xHP1α-GFP. These data are consistent with the binary switch hypothesis and suggest that one of the outcomes of histone H3 serine 10 phosphorylation during M phase by the CPC is dissociation of HP1 from chromosomes. 1. W. Fischle, Y. Wang, C. D. Allis, *Nature* **425**, 475 (2003).

860

**Structural Analysis of the Interaction Between the Cohesin Complex and Cohesin Attachment Regions**

A. Surcel,[1] R. T. Simpson[2]; [1]Huck Institute for the Life Sciences, Pennsylvania State University, University Park, PA, [2]Biochemistry and Molecular Biology Department, Pennsylvania State University, University Park, PA

Sister chromatid cohesion is facilitated by the multimeric protein complex known as cohesin. From late G1 phase to mitotic metaphase, the cohesin complex binds to specific sequences along chromosome arms identified in *Saccharomyces cerevisiae* as Cohesin Attachment Regions (CARs). These DNA sequences are interspersed on average by 9kb and show no sequence similarity to each other. This lack of sequence homology, coupled with cohesin dependence on the chromatin remodeling factor RSC, suggests that the underlying chromatin structure of these loci may be important. There are currently three main models for cohesin binding - the embrace model, the snap model and the physical contact model. To determine the feasibility of these models, we are using the Minichromosome Affinity Purification (MAP) method to investigate the ultrafine structure of CARs when bound by cohesin. Isolated minichromosomes are analyzed by transmission electron microscopy. Our data indicates that this method is a viable option for assessing model accuracy of cohesin maintenance at CAR loci. We are also performing large-scale, low-resolution nucleosome mapping of CARs and cohesin loading loci to determine whether chromatin structural changes occur concurrently with cohesin binding or loading. Our preliminary data suggests that scc2/4 binding sites - the places of cohesin loading - undergo nucleosome protection during S-phase, implying that a changing chromatin structure may be important for sister chromatid cohesion.

**The Human Mitotic Checkpoint Protein BubR1 Regulates Chromosome-Spindle Attachments**

M. A. Lampson, T. M. Kapoor; Laboratory of Chemistry and Cell Biology, Rockefeller University, New York, NY

Loss or gain of whole chromosomes, the form of chromosomal instability most commonly associated with human cancers, is expected to arise from the failure to accurately segregate chromosomes in mitosis. The mitotic checkpoint is one pathway that prevents segregation errors by blocking anaphase onset until all chromosomes make proper attachments to the spindle. Another process that prevents errors is stabilization and destabilization of connections between chromosomes and spindle microtubules. An outstanding question is how these two pathways are coordinated to ensure accurate chromosome segregation. We find that in human cells depleted of BubR1, a critical component of the mitotic checkpoint that can directly regulate anaphase onset, chromosomes do not form stable attachments to spindle microtubules, as indicated by several independent assays. Kinetochores of these cells lack cold-stable microtubule fibers and contain high levels of Mad2 and the dynactin component p150. Stable attachments are restored in BubR1-depleted cells by Aurora kinase inhibition, which is known to stabilize kinetochore-microtubule attachments. Loss of BubR1 function thus perturbs regulation of attachments rather than the ability of kinetochores to bind microtubules. Consistent with this finding, depletion of BubR1 increases phosphorylation of CENP-A, a kinetochore-specific Aurora kinase substrate. We propose that BubR1 links regulation of chromosome-spindle attachment to mitotic checkpoint signaling.

**Localization of Emi1 to the Spindle Poles Spatially Restrains APC/C Activity to Maintain Spindle-associated Cyclin B and Spindle Assembly**

K. Ban,[1] J. Torres,[2] J. Miller,[2] M. Nachury,[2] P. Jackson[2]; [1]Program in Cancer Biology, Stanford University, Stanford, CA, [2]Pathology, Stanford University, Stanford, CA

Cell cycle progression depends on the ordered and timely destruction of substrates by the anaphase-promoting complex (APC/C), an E3 ligase that targets substrates for ubiquitination. Emi1 inhibits the APC/C during S and G2 to allow the accumulation of cell cycle substrates. In early mitosis, the bulk of Emi1 is destroyed, permitting the destruction of a subset of substrates such as cyclin A. In contrast, mitotic substrates such as cyclin B and securin are not destroyed until anaphase. This stability is due in part to the inhibition of the APC/C by the spindle checkpoint, but it is unclear how additional mechanisms help to restrain APC/C activity while checkpoint signals are established. Here, we show that a population of Emi1 localizes to the spindle poles and provides spatial regulation of APC/C activity important for proper spindle assembly. Using immunofluorescence, we demonstrate that the localization of Emi1 to the poles occurs at nuclear envelope breakdown and requires microtubules and the minus-end directed dynein-dynactin motor complex. Purification of the Emi1 complex further identified the spindle pole organizer NuMA together with components of the APC/C, suggesting a localized regulatory network at the mitotic spindle poles. Consistent with this idea, siRNA knockdown of Emi1 in mitotic cells leads to reduction of spindle associated cyclin B on the spindle causing mislocalization of spindle organizing proteins NuMA/dynactin and formation of aberrant spindles that fail to congress chromosomes. Similarly, immunodepletion of Emi1 from *in-vitro* aster assembly reactions causes premature loss of cyclin B/cdk1 activity and inability to organize microtubules into asters. Together these findings support a model that localization of Emi1 to the poles spatially restrains APC/C activity to maintain spindle-associated cyclin B important for pole

integrity and spindle assembly.

**Centromere-specific Role of the Cohesin Complex in *Xenopus* Egg Extract**

R. Deehan Kenney, R. Heald; UC Berkeley, Berkeley, CA

Cell propagation requires accurate replication and segregation of the genetic material. To facilitate their accurate distribution by the mitotic spindle, sister chromatids are tethered during DNA replication and simultaneously released at the metaphase to anaphase transition, allowing for their separation to opposite spindle poles. The highly conserved, multi-subunit cohesin complex is fundamental to this process, yet its role in mitosis is not fully understood. To characterize cohesin function, we immunodepleted the complex from *Xenopus laevis* egg extracts. Loss of cohesin resulted in unpaired sister chromatids that failed to align on the metaphase plate, and aberrant chromatid distribution during anaphase. Topologically linking metaphase chromosomes by inhibiting topoisomerase II (topo II) partially rescued metaphase compaction and alignment defects but did not restore sister chromatid cohesion. Chromosomal passenger proteins Incenp and Aurora B did not target to centromeres properly in the absence of cohesion, however, this could be rescued by addition of monastrol, thereby relieving bipolar spindle tension on the kinetochores. The dynamic redistribution of passenger proteins to the midzone during anaphase was unaffected. When both condensin and cohesion were immunodepleted, we observed an additive effect on spindle assembly, and a rescue of the kinetochore stretching caused by condensin depletion. These data underscore the essential requirement for cohesin in sister chromatid cohesion, targeting of passenger proteins and kinetochore function.

864

**Histone Depletion Causes Altered Centromere Clustering and Spindle Structure in Budding Yeast**

D. C. Bouck, K. Bloom; Biology, University of North Carolina at Chapel Hill, Chapel Hill, NC

Prior to anaphase onset, sister chromatid pairs align along the metaphase plate of the mitotic spindle. During this step of mitosis, the mitotic spindle is stabilized by interdigitated interpolar microtubules, while kinetochore microtubules exert poleward force on chromosomes at kinetochore-centromere attachment sites. The poleward pulling force is opposed by cohesion along the arms of the sister chromatids. The balance of these opposing forces results in an equilibrium where centromeres remain fairly organized along the metaphase plate. The contributions of microtubule dynamic instability, motor proteins, microtubule-associated proteins, kinetochores, and cohesion complexes in this process have been previously explored and remain under active investigation. In this study, we have undertaken the analysis of mitotic spindle structure during metaphase in cells where chromatin structure has been altered. By downregulating the transcription of histone genes, we have perturbed a key member of the metaphase spindle, thus allowing us to better understand the contribution of chromatin as a structural element. Using budding yeast strains where histone H3 or H4 transcription is under the repressible galactose promoter, we have lowered the concentration of nucleosomes in the cell and examined the effects on mitotic spindle structure. Spindles are longer after histone depletion, suggesting that spindle length is physically restrained by the inward force due to chromosome arm cohesion. We have also found that centromeres are de-clustered during metaphase after histone depletion. This might be caused by the loss of persistent microtubule-kinetochore attachment, or variability in kinetochore microtubule length. These results indicate that chromatin packaging is a significant factor in the alignment of sister chromatids in metaphase and contributes to the overall structure of the mitotic spindle.

865

**Requirement of Plus-end Microtubule Dynamics for Proper Spindle Pole Assembly at the Centrosomes**

J. Hornick, J. Breunig, K. T. Vaughan, E. H. Hinchcliffe; Biological Sciences, Univ. Notre Dame, Notre Dame, IN

The poles of the mitotic spindle are assembled by the pair of centrosomes, which recruit structural proteins, such as NuMA, to the minus ends of microtubules (MTs). Dynamic MTs are necessary for proper formation of mitotic spindle poles; NuMA is transported to the spindle pole in a dynein-dependant fashion, which itself requires dynamic MT plus-ends for “search-capture”. To investigate the mechanisms of spindle pole assembly, BSC-1 cells constitutively expressing either GFP-α tubulin or GFP-NuMA were continuously treated with μM concentrations of Taxol to completely suppress plus-end microtubule dynamics, and then imaged by time-lapse fluorescence video microscopy as they entered mitosis. At the onset of mitosis, the microtubule network in Taxol-treated cells dissociates from the centrosome, and microtubules are recruited to the nuclear envelope and the cell cortex. The duplicated centrosomes often fail to separate, do not remain attached to the nucleus, and fail to assemble prominent microtubule asters. A significant number of centrosomes do not have any microtubules associated with them. In addition, suppressing microtubule dynamics leads to significant delays in nuclear envelope breakdown, resulting in NuMA “leaking” out of the nucleus, and moving predominately to the cortex, rather than to the centrosomes. Unexpectedly, the cortically arrayed NuMA and microtubules bud off into multiple cytasters, which migrate, cluster and fuse together around the chromosomes, but fail to assemble a proper bipolar microtubule array. This ultimately leads to failure of cytokinesis, and the generation of a polyploid cell. Our data are consistent with the model that plus-end microtubule dynamics are required for search-capture during prophase to properly localize NuMA, thereby ensuring that the spindle poles assemble only at the centrosomes. Our live-cell imaging has also directly revealed the cellular mechanism for the anti-mitotic activity of Taxol.

866

**Defective Centrosomal and Spindle Functions after Protein 41R Downregulation**

J. R. Spence,[1] M. Go,[1] S. Bahmanyar,[2] A. Barth,[2] W. J. Nelson,[2] S. W. Krauss[1]; [1]Genome Biology, UC-LBNL, Berkeley, CA, [2]Molecular and Cellular Physiology, Stanford University School of Medicine, Palo Alto, CA

Multifunctional structural proteins, serving as adaptors or linkers, are essential for cellular remodeling processes. Protein 4.1R was initially characterized as a crucial ~80kD structural component of mature red cells with well-defined functions stabilizing interactions within spectrin-actin lattices and cytoplasmic domains of transmembrane proteins. In nucleated cells, we previously characterized 4.1 as an integral “core” centrosome component, colocalizing with centriolar tubulin, in the surrounding pericentriolar matrix, and on fibers connecting centriolar pairs. As multifunctional structural proteins, centrosomal 4.1 isoforms could serve as structural elements linking components to impart dynamic properties and fidelity needed for centrosomal functions. Using an open-cell *Xenopus* extract system, we showed that 4.1 is essential for spindle and centrosome assembly and for regulation of microtubule dynamics and organization. Current investigations in mammalian cells include both 4.1R

(red cell) and another family member, 4.1G (generally distributed). Using 4.1 gene-specific antibodies we observed that both 4.1R and 4.1G localize at centrosomes but have differential subcentrosomal distributions during the cell cycle. To probe 4.1R function, we specifically downregulated 4.1R expression by RNAi and characterized a unique phenotype relating to centrosomal dysfunction: (1) interphasic cells with disorganized tubulin not emanating from a centrosomal focus and multinucleated cells often containing disparate-sized nuclei; (2) perturbed ninein distribution at mature centrioles; (3) decreased frequency of mature centriole separation preceding entry into mitosis; (4) monopolar and multipolar mitotic spindles with misaligned decondensed chromatin, disorganized microtubules and mislocalized NuMA; (5) defective cytokinesis including chromosome missegregation, spindle dysmorphology, and improper tubulin bridge formation. These data suggest that 4.1R, acting as an adaptor or linker to multiple mitotic targets, could affect cell division by regulating the architectural integrity of cell division machinery. Based on our data we are analyzing 4.1 interactions impacting microtubule nucleation/anchoring, chromatin condensation and motor-dependent microtubule organization.

**Human Sgo1 is Essential for the Maintenance of Centromeric Cohesion of Sister Chromatids During Mitosis**

X. Wang, Y. Yang, W. Dai; Medicine, New York Medical College, Valhalla, NY

Human Sgo1 is essential for the maintenance of sister chromatid cohesion Xiaoxing Wang, Yali Yang, Wei Dai, New York Medical College, Valhalla, NY 10595 Sister chromatid cohesion relies primarily on the cohesin complex, which consists of Smc1, Smc3, Scc1 (Rad21), and Scc3. Cohesin forms a ring structure that may help to entrap DNA molecules. In high eukaryotes such as mammals, cohesin molecules are dissociated from chromosomal arms but not from centromeres during early mitosis by the so-called “prophase pathway”. Although the molecular basis by which centromeric cohesin is retained remains unclear, recent studies have shed light on an evolutionarily conserved protein called Shogoshin (Sgo) that may explain the delayed removal of centromeric cohesin until the anaphase onset. In HeLa cells, a major fraction of Sgo1 is localized to kinetochores during prophase and metaphase, during which it is phosphorylated and exhibits a significant mobility shift on SDS gels. Suppression of Sgo1 via RNA interference causes massive mitotic arrest and chromosome mis-segregation. Mitotic arrest induced by Sgo1 depletion is accompanied by partial inactivation of BubR1 and Mps1, two major spindle checkpoint components, whereas no significant change of cohesin levels is detected. Moreover, phospho-MEK and phospho-ERK levels are significantly increased in mitotic cells induced by Sgo1 depletion but not by nocodazole treatment. Our studies thus indicate that Sgo1 plays a critical role in mediating integrity of kinetochores during mitosis and that dysregulated function of Sgo1 may be one of the major underlying causes for chromosomal instability and aneuploidy.

***Drosophila* Myb is Required for Centromere Maintenance**

J. Manak,[1] S. Heidmann,[2] D. Georlette,[3] T. Van,[1] J. Lipsick[1]; [1]Pathology and Genetics, Stanford University, Stanford, CA, [2]Genetics, University of Bayreuth, Bayreuth, Germany, [3]Molecular and Cell Biology, University of California, Berkeley, CA

In most eukaryotic cells, centromeres are essential for chromosome segregation. CID/CENP-A, a centromere-specific histone H3 variant, is required to localize other centromere-binding proteins. However, little is known about the deposition and maintenance of CID itself. DmMYB, the Drosophila homologue of the MYB oncoprotein family, is required for organismal viability and genomic stability. Previous work has shown that DmMYB localizes to newly replicated DNA and is required for the switch from genome-wide DNA replication to site-specific chorion gene amplification in endocycling ovarian follicle cells. Diploid, mitotically cycling cells can proliferate in the absence of DmMYB, but eventually display an increased frequency of arrest with partially condensed chromosomes as well as defects in chromosome segregation. We now show that DmMYB is required for the proper maintenance of CID at the centromere. In addition, DmMYB is necessary for the non-centromeric deposition of overproduced CID. These results suggest that DmMYB is required for the generation and/or maintenance of chromatin states that are permissive for the replacement of histone H3 by CID.

## G2-M (869-879)

869

**Cyclin A Regulates Mitotic Spindle Orientation**

H. Beamish, L. DeBoer, F. Stevens, B. G. Gabrielli; Centre for Immunology and Cancer Research, University of Queensland, Brisbane, Australia

Cell cycle progression is controlled by the ordered activation of the cyclin/cdk protein kinases. Progression into mitosis is controlled by the activation of cyclin B/cdk1, but progression through G2 phase and the events regulating the timing of cyclin B/cdk1 activation are still poorly understood. The role of cyclin A/cdk2 in cell cycle progression is complex. A pool is activated in early S phase and appears to be required for S phase progression, but a larger pool is activated in early G2 phase and its role is unknown. Inhibiting the cdk2 activity by over expressing a dominant negative cdk2 or using specific cdk2 inhibitors blocks progression into mitosis. We have investigated the function of cyclin A/cdk2 during G2 phase. We have established siRNA knockdown of cyclin A and its immediate upstream activator, cdc25B. Using time lapse videomicroscopy, fluorescence microscopy and flow cytometric techniques we have demonstrated the knockdown of either cyclin A or cdc25B produces a delayed entry into mitosis by blocking the activation of cyclin B/cdk1. However, the cells do eventually proceed into mitosis, where a number of condensed chromosomes fail to congress to the metaphase plate initiating the mitotic spindle checkpoint. The surprising feature of this arrest is that the established mitotic spindle with attached chromosomes rotates within the cell. Consequently there is a significant increase in the number of cells that undergo anaphase and cytokinesis out of the normal plane. The unexpected findings indicate a role for cyclin A/cdk associated with the mitotic spindle. To this end we have found cyclin A localised to the spindle poles prior to metaphase. This finding provides evidence for a previously unknown role for cyclin A/cdk in spindle formation and function in mitosis.

**A Potent G2-Phase Checkpoint Response to DNA Damage Induced by the Topoisomerase Inhibitor Adriamycin Requires Upregulation of Cyclin G2**

A. S. Arachchige Don, R. Dallapizza, C. Cowan, T. Weisenhorn, J. Duven, M. C. Horne; Pharmacology, University of Iowa, Iowa City, IA

Cyclin G2 (G2) is a unique, poorly understood stress-response protein possessing proliferation inhibitory activity. G2 expression is induced in response to DNA damage and other cellular stresses, but inhibited by activation of the proliferation promoting PI3K/AKT survival pathway. We showed that ectopic G2 expression results in a p53-dependent cell cycle arrest that also requires G2 association with protein phosphatase 2A, although the precise mechanism whereby elevated G2 promotes this arrest is unknown. We have recently determined that G2 is a centrosomal and nucleocytoplasmic shuttling protein. We found that treatment of Her2 positive breast cancer cells with Herceptin® (monoclonal antibody that blocks Her2 receptor-mediated PI3K/AKT pathway) or the PI3K Inhibitor (Ly294002), strongly upregulate cyclin G2 expression. *We hypothesize that dysregulation of G2 expression, interactions, or subcellular localization, leads to a loss of cell cycle control, ultimately promoting tumor formation.* Here, we seek to determine whether elevated G2 expression is necessary for the growth inhibitory effects induced by current chemotherapeutic agents relevant to cancer. Interestingly, Herceptin® treatment combined with a first line therapy that includes topoisomerase inhibitor and DNA damaging agent, Adriamycin®, improves survival rates and reduces the risk of breast cancer recurrence in premenopausal women. We treated cells with Adriamycin® in the presence or absence of cyclin G2 depletion via G2-specific shRNA and examined the effects on cellular proliferation via DNA flow cytometry. We found that Adriamycin® potently upregulates G2 expression and remarkably, depletion of endogenous cyclin G2 in Adriamycin®-treated cells abrogates the normal $G_2$-phase cell cycle arrest response. As chemotherapeutic agents induce G2 expression and G2 exhibits intrinsic growth inhibitory activity, understanding how G2 contributes to modulation of cellular proliferation is highly warranted and may provide future avenues for improved therapies.

871

**Synergistic Regulation of Mitosis by B Type Cyclins**

D. V. Soni, J. W. Jacobberger; Case Western Reserve University, Cleveland, OH

Cyclin B1/Cdk1 is a key regulator of mitosis with functions in nuclear membrane breakdown and the spindle checkpoint. We have measured the effect of siRNA-mediated depletion of cyclin B1 on the mitotic transition of HeLa cells by flow cytometry and time-lapse microscopy. The loss of cyclin B1 and its associated Cdk1 activity by at least 96% delayed the progression of cells from G2 through metaphase. Cyclin B1 depleted metaphase cells displayed a high frequency of lagging chromosomes that often failed to congress. However these cells entered anaphase and transited the rest of mitosis and cytokinesis with normal kinetics. In the presence of nocodazole, cyclin B1-depleted cells arrested in mitosis but eventually exited mitosis without completing cytokinesis and entered a 4C G1 state. Depletion of both cyclin B1 and cyclin B2 from HeLa cells by RNA interference resulted in a prolonged G2 arrest with failure to enter mitosis. We conclude that cyclin B1 is rate limiting for transition through metaphase and for maintaining the efficiency of chromosome congression and the spindle checkpoint. Moreover, while only one of the B type cyclins is required for the mitotic progression of HeLa cells, together cyclin B1 and B2 act synergistically to ensure efficient mitosis.

872

**TSPY Interacts with Cyclin B1 and Promotes G2/M Transition by Regulating the Cyclin B1/CDK1 Activity**

Y. LI, S. Oram, Y. C. Lau; Department of Medicine, University of California, San Francisco, VA medical Center, San Francisco, CA

The testis-specific protein Y-encoded (TSPY) gene has been mapped on the gonadoblastoma locus on the Y chromosome (GBY). TSPY is a tandemly repeated gene that expresses abundantly in normal testis, gonadoblastoma, testicular carcinoma-in-situ and seminoma, and in prostate cancer tissues and cell lines. TSPY contains a conserved domain present in a family of cyclin B binding proteins, including the oncoprotein SET. To confirm the putative cyclin B binding function, we have performed various interactive analyses between TSPY and cyclin B1, using the GST pull-down and co-immunoprecipitation assays. Two domains, residue #152-180 and #200-220 in the TSPY protein are important for its interaction with cyclin B1. A specific region, residue #302-314, in cyclin B1 is essential for binding to TSPY domains. Further, TSPY can be co-immunoprecipitated with a specific antibody against cyclin B1. TSPY colocalizes with cyclin B1 in both the nuclei and cytoplasm of transfected cells. It enhances the phosphorylation activity of cyclin B1/CDK1 complex on the substrate, histone H1. TSPY, in turn, can also be phosphorylated by the same complex. Over-expression of TSPY in HeLa cells shortens the G2/M transition. Our data suggest that TSPY regulates the cell cycle by binding to cyclin B1, thereby accelerating a rapid G2/M transition and modulating the cyclin B1/CDK1 activity.

873

**Tspy Expression Increases Cell Proliferation, Tumorigenesis, and Effects Cell Cycle Progression of Hela and Nih3t3 Cells**

S. W. Oram, X. Liu, Y. Lau; Medicine, UCSF- VA Medical Center, San Francisco, CA

TSPY is a gene located on the Y chromosome and has between 20-40 copies in humans. Deletion mapping of the gonadoblastoma locus on the Y chromosome has identified TSPY as the most likely candidate. Elevated levels of TSPY have been observed in gonadoblastoma specimens and TSPY expression has been observed in a variety of other tumor tissues: testicular germ cell tumors such as seminoma, non-seminoma, carcinoma *in situ*, and also in prostate cancer and melanoma. TSPY harbors a NAP/SET domain that is found in the oncoprotein SET and the nucleosome assembly protein 1 (NAP1), suggesting a possible role for TSPY in these processes. However, no cellular function has been definitely established for this Y-encoded protein. To determine if TSPY plays a role in cell cycle regulation and/or oncogenesis, we have established a Tet-off regulated system for TSPY expression in HeLa and NIH3T3 cells. We demonstrate that expression of TSPY increases cell proliferation *in vitro* and tumorigenicity *in vivo*. TSPY mediates changes in the cell cycle profile of these cells, resulting in a smaller population of cells in the G2/M phase of the cell cycle. Using cell synchronization techniques, we show that TSPY appears to effect a G2/M transition at a faster rate. These findings provide the first insights on the role of TSPY, demonstrating that TSPY is involved in the regulation of cell cycle progression, and abnormal expression of TSPY increases cell proliferation and tumorigenicity of host cells in culture and nude mice.

874

**Cantharidin-Induced Mitotic Arrest and Subsequent Apoptosis is Associated with the Formation of Aberrant Mitotic Spindles and Improperly Aligned Chromosomes Resulting, in Part, from the Suppression of PP2Aα Activity in Human Cells**

K. M. Bonness,[1] B. Rutland,[2] N. Dean,[3] R. Honkanen[2]; [1]Center for Lung Biology, Dept of Biochemistry and Molecular Biology, University of South Alabama, Mobile, AL, [2]Dept of Biochemistry and Molecular Biology, University of South Alabama, Mobile, AL, [3]ISIS Pharmaceuticals, Carlsbad, CA

Cantharidin is an inhibitor of serine/threonine protein phosphatases (PP1, PP2A, PP4, and PP5) that displays marked anti-tumor activity. To explore the molecular mechanisms associated with the anti-tumor activity of cantharidin, we examined the cellular effects produced in human cells. Cantharidin produces an apoptotic response at concentrations inhibiting >50% of the activity in the serine/threonine phosphatases. Additionally, cantharidin produces a dose-dependent growth arrest during G2/M-phase. The maximal response is achieved at 3-4μM cantharidin, which is sufficient to completely suppress the activity of PP2A, PP4 and PP5 while partially suppressing the activity of PP1. FACS analysis of synchronized A549 cells treated with cantharidin revealed a typical progression through the cell cycle until G2/M-phase where they arrested. The addition of cantharidin to synchronized cells at timed intervals, which were consistent with the G1-, S-, and G2-phases of the cell cycle, also triggered G2/M growth arrest. This suggests that the critical event arresting cell cycle progression occurs during the G2/M-phase. Immunostaining indicates that growth-arrest occurs prior to the completion of mitosis since it is associated with the formation of numerous abnormal mitotic spindles and condensed chromosomes that fail to align properly along the metaphase plate. Prolonged disruption of both the mitotic spindle and chromosome alignment is followed by an apoptotic response that likely contributes to the antitumor activity of cantharidin. Furthermore, inhibition of phosphatase expression using siRNA and antisenses oligonucleotides indicates that PP2Aα is crucial for completion of mitosis and progression through the cell cycle. Fluorescent microscopy of PP2Aα anti-sense treated cells illustrates a similar phenotype in which chromosomes fail to align properly during a prolonged growth arrest and subsequent apoptosis.

875

**ERK1/2 and Mitosis in Mammalian Cells**

M. Shinohara,[1,2] A. V. Mikhailov,[2] C. L. Rieder[1,2]; [1]Department of Biomedical Sciences, State University of New York, Albany, NY, [2]Lab. of Cell Regulation, Department of Molecular Medicine, Wadsworth Center, Albany, NY

The extracellular signal-regulated kinase (ERK) 1/2 pathway is required for the $G_1$/S transition. When activated it facilitates protein syntheses, induces cytoskeletal rearrangement and activates transcription of cell cycle regulators including cyclins D and E. After S phase, however, the role of ERK signaling becomes controversial. Biochemical studies suggest that ERK1/2 activity is required for the $G_2$/M transition, Golgi fragmentation and the spindle assembly checkpoint. Yet evidence is accumulating that receptor-mediated ERK1/2 activation is suppressed during mitosis. The goal of our study was to determine if ERK activity is required for mammalian cells to progress normally into and through mitosis. For this we used high-resolution time-lapse microscopy to follow cell cycle progression both temporally and phenotypically in human retinal pigment epithelia (hTERT-RPE1) and rat kangaroo ($PtK_1$) cells treated with either a small molecule inhibitor (U0126) or activator (TPA) of the ERK pathway. To avoid the effects of ERK pathway intervention on gene expression we treated cells during late $G_2$ (antephase), approx. 1 hr before they became committed to mitosis. We found that these treatments had no influence on the kinetics of mitotic entry and exit in both cell lines. Treated cells also exhibited normal chromosome condensation, nuclear envelope breakdown, chromosome congression, sister chromatid separation and cytokinesis. Immunofluorescence revealed normal, bipolar spindle formation. We also found that ERK1/2 activity was dispensable for initiating or maintaining the spindle assembly checkpoint. There was, however, a slight increase in the early $G_2$ cell population 1-4 hrs after U0126 treatment. Together, the ERK1/2 cascade is not required for late $G_2$ cells to enter or proceed through mitosis.

876

**The Presence/Activity of Chk1 in the UV-induced Cellular Response in the Purple Sea Urchin, *Strongylocentrotus purpuratus***

G. A. Goschke, N. L. Adams; Biological Sciences, California Polytechnic State University, San Luis Obispo, CA

Chk1 is a protein kinase known in some organisms to be involved in ultraviolet radiation (UVR)-induced DNA damage response and may regulate proteins downstream involved in the G2/M transition of the cell cycle. G2/M arrest is regulated by the mitosis-promoting factor (MPF), which is a complex of Cdc2 and cyclins. Cdc2 is activated by Cdc25 (a protein phosphatase), a crucial step in the entry into M-phase of the cell cycle. Phosphorylation of Cdc25 at ser 216 prevents activation of Cdc2. Cdc25 is phosphorylated throughout interphase, but not in mitosis. Chk1 (an upstream kinase) in turn phosphorylates Cdc25 and thereby inhibits mitosis. Previous studies of sea urchin embryos have shown that UVR exposure induces cellular response to UVR damage via cell cycle delays at the G2/M transition, but the molecular aspects of this response are unclear. In addition to this delay, when exposed to UVB (280-320 nm), sea urchin gametes and zygotes exhibit both immediate and delayed effects on both morphology and physiology in mitosis in response to UVR. Our previous results demonstrated that UV-irradiation of sea urchin eggs causes a delay in dephosphorylation of Cdc2 at tyr 15 (preventing activity of Cdc2). In our current study, we have examined whether an upstream regulator of Cdc2 activity, Chk1, is present in sea urchin eggs and embryos and has a similar function in response to UVR as exists in other organisms. We performed sequence alignments with human Chk1 and the currently available sea urchin genome sequence. We performed SDS PAGE and western blotting of sea urchin embryo lysates using antibodies generated against human Chk1. Our results indicate that Chk1 is likely to be present in sea urchins eggs and embryos.

877

**Non-catalytic Function for Xenopus ATR in the S/M Checkpoint Response**

T. D. McSherry,[1] A. A. Kitazono,[2] A. Javaheri,[1] S. J. Kron,[1] P. R. Mueller[3]; [1]Center for Molecular Oncology, University of Chicago, Chicago, IL, [2]Biochemistry, Cellular, and Molecular Biology, University of Tennessee at Knoxville, Knoxville, TN, [3]Biology, University of Texas at San Antonio, San Antonio, TX

The ATR family of checkpoint kinases is essential for an appropriate checkpoint response. These large kinases phosphorylate and modify multiple cell cycle and checkpoint factors, leading to cell cycle arrest, DNA repair, and induction of apoptosis. The catalytic domain of all ATR family members comprises only a small fraction of the total protein, leaving unresolved the function of the majority of the protein. Biochemical structure/function analyses of Xenopus ATR (XATR) in Xenopus extracts have been hampered by the large size of ATR. To address this problem, we have used a cross species approach designed to take advantage of the high degree of homology between metazoan and yeast ATR family members. We examined XATR function by exploring its ability to suppress the S/M checkpoint deficient phenotype of a *S. cerevisiae* ATR homolog *mec1* mutant. Expression of wild type, kinase dead, or an amino terminal portion of XATR in a *mec1* mutant suppresses the S/M checkpoint defect and induces the DNA damage dependent mitotic cell cycle arrest. This suppression functions independently of Rad9 modification and Rad53 activation. In addition, XATR expression suppresses the checkpoint defects of other various checkpoint mutants. Together,

these results indicate that XATR is not functioning through the established S/M checkpoint pathways. Instead, we find that XATR suppression of the *mec1* mutant checkpoint defect requires Mad1/2 of the spindle assembly checkpoint, suggesting that XATR is functioning through this pathway. Finally, expression of kinase dead and truncation constructs of the yeast ATR homolog, MEC1, in the *mec1* mutant also partially suppresses the S/M checkpoint defect and induces a mitotic cell cycle arrest in a Mad1 dependent manner. Thus, the link between the non-catalytic region of the ATR kinase family and the spindle checkpoint pathway is conserved between yeast and metazoans.

### Control of Mitotic Entry by MIH1, the Budding Yeast Homolog of CDC25

G. Pal, D. R. Kellogg; Department of Molecular, Cellular, and Developmental Biology, University of California, Santa Cruz, Santa Cruz, CA

Entry into mitosis is induced by activation of cyclin-dependent kinase 1 (Cdk1) and is highly regulated. The Wee1 kinase delays entry into mitosis by phosphorylating and inhibiting Cdk1, while the Cdc25 phosphatase promotes entry into mitosis by dephosphorylating Cdk1. In fission yeast, Wee1 and Cdc25 are thought to coordinate cell growth with entry into mitosis; however, the physiological signals and molecular mechanisms that regulate Wee1 and Cdc25 are poorly understood. Recent work has shown that the budding yeast homolog of Wee1 may also function to coordinate cell growth with entry into mitosis, but the functions of budding yeast Cdc25 have not been carefully characterized. The homolog of Cdc25 in budding yeast is called Mih1. We found that loss of Mih1 causes cells to delay at G2/M while still undergoing growth, indicating that the basic functions of fission yeast Cdc25 have been conserved in budding yeast Mih1. To better understand the Mih1-dependent mechanisms that control entry into mitosis, we are characterizing how Mih1 is regulated. Interestingly, Mih1 undergoes constitutive hyperphosphorylation during the cell cycle and becomes dephosphorylated as cells enter mitosis. Dephosphorylation of Mih1 is triggered by mitotic Cdk1 activity, which suggests that Cdk1 activates a phosphatase that dephosphorylates and further activates Mih1. We are currently working to identify the phosphatase and the kinase that regulate Mih1.

### Dot2, the Fission Yeast Homolog of Human EAP30, Blocks Meiotic Spindle Pole Body Amplification

Y. Jin, J. J. Mancuso, S. Uzawa, D. Cronembold, W. Z. Cande; Department of Molecular and Cell Biology, UC, Berkeley, Berkeley, CA

Centrosome aberrations caused by misregulated centrosome maturation result in defective spindle and genomic instability. Here we report that the fission yeast homolog of human EAP30, Dot2, negatively regulates meiotic Spindle Pole Body (SPB, the yeast equivalent of centrosome) maturation. dot2 mutants show excess electron-dense material accumulating nearby SPBs seen as enlarged SPBs or multiple SPB-like structures, which we refer to as Aberrant Microtubule Organization Centers (AMtOCs). SPB aberrations were associated with elevated Pcp1 protein level, the fission yeast ortholog of pericentrin/kentrin. Replacement of the endogenous pcp1+ promoter by a foreign promoter can significantly suppress AMtOCs in dot2-439 cells, indicating that Dot2 regulates pcp1+ expression. Dot2::GFP is colocalized with Mei2 as a spot on a chromosome in the nucleus and genetically interacts with Sme2, a RNA that is binds to Mei2. Our findings provide the first evidence that a member of the widely conserved EAP30 family is required for maintenance of genome stability by regulating SPB maturation and also indicate a meiosis-specific regulation of SPB maturation. In addition to its nuclear function, Dot2 is also found involved in vacuolar protein transport and sorting in vegetativly- growing fission yeast cells (Kaoru Takegawa, personal communication).

### Understanding cell division: A forward genetics approach

J. C. Canman, B. Bowerman; Institute of Molecular Biology, University of Oregon, Eugene, OR

Accurate cell division is crucial for preventing aneuploidy during both development and cell differentiation. The early *C. elegans* embryo is a powerful model system for identifying genes required for cell division. Many genes required for cell division in *C. elegans*, however, are also required for germline development and gonad function. Therefore disruption of these genes results in sterility- precluding analysis of any potential gene function in the early embryo. To overcome this pitfall, we have developed a forward genetics approach to isolate conditional alleles of genes involved both in gonad function as well as cell division in the early embryo. We first isolated ~100 mutants that could make viable offspring at the permissive temperature (15°C) but became sterile if shifted to the restrictive temperature (26°C) at the L4 larval stage (after the majority of gonad development has occurred). We then took advantage of the conditional nature of these mutations to determine which mutants are defective in cell division. To do this, we shifted adult worms from the permissive to the restrictive temperature after they began producing embryos, and then imaged the first two embryonic cell cycles using DIC microscopy. Using this approach, we have screened through about half of the mutant collection and have identified four several mutants with both sterility defects and embryonic cell division defects. We are currently examining the cellular defects in these mutants, and mapping the mutations to determine gene identity.

881

### Rho-kinase Plays a Pivotal Role in Triggering the Earliest Shape Changes of Cytokinesis in *Drosophila* S2 Cells

G. R. X. Hickson,[1] A. Echard,[2] P. H. O'Farrell[1]; [1]Dept. Biochemistry & Biophysics, University of California, San Francisco, San Francisco, CA, [2]Cnrs umr144, Institut Curie, Paris, France

Animal cell cytokinesis is characterized by a sequence of dramatic cortical rearrangements. The mechanisms that coordinate these rearrangements and couple them with mitosis are largely unknown. In efforts to explore the initiation of cytokinesis, we have focused on anaphase cell elongation: the earliest cell shape change that occurs in concert with anaphase B, prior to cytokinetic furrowing. Using RNAi and live video-microscopy in *Drosophila* S2 cells, we implicate Rho-kinase (Rok) and myosin II in anaphase cell elongation. *rok* RNAi prevented equatorial myosin II recruitment, prevented cell elongation and caused a remarkable spindle defect where the spindle poles collided with an unyielding cell cortex and the interpolar microtubules continued to extend and buckled outwards. Disruption of the actin cytoskeleton with Latrunculin A alleviated the spindle defect, consistent with cortical dysfunction being primary. Despite failure of cell elongation and spindle disruption, cytokinesis often succeeded following *rok* RNAi. Co-suppression of the myosin binding subunit (MBS) of myosin phosphatase, which is known to antagonize Rok

activation of myosin II, suppressed any failures in cytokinesis that were induced by *rok* RNAi, but did not suppress the failures in cell elongation. The marked sensitivity of cell elongation to Rok depletion was highlighted by RNAi to other genes in the Rho pathway, such as *Pebble*, *RacGAP50C* and *Diaphanous* which had little or no effect on cell elongation but had profound effects on furrowing. Our results show that cell elongation in anaphase requires Rok and myosin II dependent cortical rearrangements and the marked sensitivity of cell elongation to depletion of these gene products as opposed to other regulators of cytokinetic furrowing suggests regulatory distinctions.

882

**RCK-1, the Mammalian RACK1 Homolog, is Required for Cytokinesis in *C elegans* Embryos**

E. Ai, A. R. Skop; Department of Genetics and Medical Genetics, University of Wisconsin - Madison, Madison, WI

Cytokinesis is an essential event required to partition chromosomes, organelles and cytoplasm to daughter cells. In animal cells, it is driven by a cortical actin-myosin contraction that forms the cleavage furrow and pinches the cell into two. The mechanisms necessary for cleavage furrow establishment and completion remain unknown. We identified RACK1 (Receptor for Activated C Kinase 1) in a proteomic screen of isolated midbodies and showed that the *C. elegans* homolog, RCK-1/K04D7.1, was required for cytokinesis (Skop et al., 2004). Because RACK1 is thought to be a scaffolding protein that mediates interactions among many signaling molecules, the requirement for this protein suggests the necessity of regulatory cascades in furrow establishment and/or completion. To address these possibilities, we are using *in vivo* imaging techniques combined with genetic and biochemical assays in both *C. elegans* and mammalian cells to further characterize the role of RCK-1 in cytokinesis. In *C. elegans* embryos, RCK-1 depletion by fRNAi results in early (38%) and late (11%) cytokinesis failures and displays 58% embryonic lethality. Defects in meiotic cytokinesis are also observed in which polar bodies fail to extrude. The spindle midzone is properly established in early anaphase, yet falls apart in late anaphase. In addition, chromosomes fail to align into the metaphase plate (10/12 embryos) and lagging chromosomes (9/12 embryos) and chromatin bridges (3/12 embryos) are seen. Furthermore, cell cycle delays are observed only during pronuclei migration and between the first and second divisions. These findings suggest that RCK-1 is required for multiple events and possibly integrates a variety of regulatory pathways during cytokinesis. Skop, A. R., Liu, H., Yates, J. 3rd, Meyer, B. J., Heald, R. *Science* 305, 61 (2004).

**Regulation of Cytokinesis by a Novel GAP Protein**

A. V. Binda,[1] A. Gromley,[2] S. J. Doxsey[1]; [1]Molecular Medicine, University of Massachusetts Medical School, Worcester, MA, [2]St. Jude's Children's Research Hospital, Memphis, TN

Completion of cell division is marked by the physical separation of two daughter cells in a process known as cytokinesis. Previously, we identified centriolin as a protein necessary for the final stage of cytokinesis, abscission. Centriolin localizes to the maternal centriole and to a ring structure at the midbody of telophase cells. Depletion of centriolin results in cytokinesis defects, most notably persistent intracellular bridges that remain between daughter cells. To determine how centriolin functions in cytokinesis, we performed a yeast two-hybrid screen using a centriolin domain homologous the *S. cerevisiae* protein, Nud1p. We identified, cloned, and sequenced a previously uncharacterized cDNA encoding a protein with homology to GTPase activating proteins (GAPs). Homology searches revealed a coiled-coil domain within the C-terminus of the GAP and a putative C2 domain within the N-terminal region. To verify the interaction of centriolin and the GAP, we performed coimmunoprecipitation assays and demonstrated an interaction between endogenous centriolin and the GAP domain. An antibody raised against the GAP stained the midbody of telophase cells, as well as at the centrosome and *trans*-Golgi network (golgin 97) throughout the cell cycle. Midbody localization was confirmed by ectopic expression of GFP-tagged constructs encoding that GAP domain and the C-terminal domain of the GAP. Midbody localization of the GAP appears to be coincident with the endosomal proteins, Rab11 and FIP3, suggesting a role for the GAP in vesicle delivery to the midbody during abscission. Consistent with this hypothesis, we found that overexpression and siRNA-mediated depletion of the GAP result in cytokinesis defects in ~40% of cells. We are currently working to identify the GTPase target of the GAP and its mechanism of action during cytokinesis.

884

**Equatorial Accumulation of RhoA-GTP During Cytokinesis**

A. J. Piekny, M. Glotzer; Molecular Genetics and Cell Biology, University of Chicago, Chicago, IL

RhoA GTPase is essential for cytokinesis in many eukaryotes as determined by genetic or biochemical studies. During anaphase the generation of the active form of RhoA, RhoA-GTP, requires both the RhoGEF ECT2 and the RhoGAP CYK-4. CYK-4, part of the centralspindlin complex, binds ECT2 and these two proteins colocalize on the central spindle. CYK-4 may act by relieving the autoinhibition of ECT2. RhoA-GTP activates several downstream effectors required for furrow formation, ingression and stabilization. To follow the localization of RhoA during cytokinesis, we generated a probe consisting of YFP fused to full-length *C. elegans* RhoA (YFP:RhoA). Unlike YFP:human RhoA, the probe based on the *C. elegans* protein localizes discretely to the equatorial cell cortex. In addition, the cortical localization of this probe is enhanced by overexpression of a RhoGEF domain and reduced by overexpression of a RhoGAP domain. Finally, YFP:RhoA localizes similarly to a RhoA-GTP binding domain (RBD) probe in sea urchin embryos and likely represents the RhoA-GTP pool. Disruption of the central spindle by MKLP1 depletion results in variable expansion of the RhoA-GTP domain. Thus, the central spindle contributes to the localization of active RhoA but a redundant mechanism contributes to RhoA-GTP localization. The differential localization of ceRhoA and hsRhoA can be attributed to a few amino acid changes, perhaps by altering the affinity toward specific binding factors. ceRhoA and hsRhoA are 94% identical in their NH2 terminus, but diverge in the C-terminus. The generation of chimeric constructs verified that the differences in their localization patterns are likely due to amino acid changes in the C-terminal portion of the protein, distinct from the CAAX box. Furthermore, we could separate regions required for RhoA-GTP accumulation and cortical localization. Experiments are in progress to identify proteins that specifically bind RhoA during its accumulation in anaphase.

885

**Dissecting the Role of Rho-mediated Signaling in Contractile Ring Formation**

K. Kamijo,[1] N. Ohara,[1] M. Abe,[1] T. Uchimura,[2] H. Hosoya,[2] J. Lee,[1] T. Miki[1]; [1]Laboratory of Cell Biology, National Cancer Institute, NIH, Bethesda, MD, [2]Department of Biological Science, Graduate School of Science, Hiroshima University, Higashi-Hiroshima, Japan

Proper positioning of the cleavage plane ensures chromosome separation and asymmetric cell division-critical steps for genome stability and

development, respectively. Although microtubules are known to provide a specification signal for positioning of the contractile ring during cytokinesis, the nature of the signal remains unknown. The implication of the small GTPase Rho in cytokinesis has been reported but it remains unclear whether Rho serves as the specification signal for positioning of the contractile ring. We have found that Rho translocates to the equatorial cell cortex before furrow ingression. The Rho specific inhibitor C3 exoenzyme prevented this translocation and disrupted contractile ring formation. Furthermore, RhoGEF ECT2 RNAi prevented translocation of Rho to the equatorial cell cortex and inhibited contractile ring formation. These results indicate that active Rho is required for contractile ring formation and that ECT2 regulates activation of Rho and its translocation to the equatorial cell cortex. MgcRacGAP and MKLP1 kinesin are required for assembly of the central spindle. We found that ECT2 co-localized with MgcRacGAP and MKLP1 at the central spindle and that the localization of ECT2 at the central spindle was dependent on MgcRacGAP and MKLP1. In addition, we have developed the experimental furrow induction system, using the Cdk1 inhibitor Roscovitine. We found that Roscovitine promoted premature exit from mitosis and induced ectopic furrows. Using this system, we have found that furrow formation depends on bundled microtubules and that Rho accumulates at the ectopic furrows. Although microtubules were bundled, ECT2 RNAi inhibited Roscovitine-induced ectopic furrowing and accumulation of Rho. Thus, we conclude that the Rho-mediated signaling acts as a link between the central spindle and contractile ring formation.

886

**Polo-like Kinase Regulates the Cortical Cytoskeleton via Multiple Rho-GTPase Regulators**

S. Yoshida,[1] K. Kono,[2] S. Bartolini,[1] D. Lowery,[3] M. Yaffe,[3] Y. Ohya,[2] D. Pellman[1]; [1]Pediatric Oncology, Dana-Farber Cancer Institute, Boston, MA, [2]University of Tokyo, Kashiwa, Japan, [3]Massachusetts Institute of Technology, Boston, MA

Cytokinesis is a dynamic process that involves highly coordinated regulation of the cortical cytoskeleton and cell cycle machinery. Cytokinetic actin ring is assembled before mitotic exit but how the cell cycle signal regulates cortical cytoskeleton reorganization during anaphase was not understood very well. We found that the Polo-like kinase Cdc5 mutants are defective in cytokinesis and in the reorganization of cortical actin cytoskeleton due to mislocalization of the cell polarity factors. A functional genomic screen was performed to identify candidate new Cdc5 substrates. By this method, Rho guanine nucleotide exchange factors (RhoGEFs) and Rho GTPase-activating proteins (RhoGAPs) were identified. Our biochemical analysis suggests that these Rho-regulators are bona fide Cdc5-substrates and these interactions were mediated by Cdk-dependent phosphorylation of the Cdc5 targets. Genetic analysis of the gain and loss of function mutations further validated an important role of Cdc5 in the regulation of Rho-GTPases. Our findings thus reveal a novel function for polo: regulation of Rho-GTPases and the cytoskeleton. Regulation of multiple Rho regulators by Polo provides a mechanism that co-ordinates cortical cytoskeletal regulation and mitotic exit to ensure successful cell division.

887

**De Novo Self-assembly of the Actomyosin Contractile Ring in Anucleate Cells**

P. T. Tran,[1] Y. Huang,[2] S. Oliferenko,[2] M. K. Balasubramanian[2]; [1]Department of Cell and Developmental Biology, University of Pennsylvania, Philadelphia, PA, [2]Cell Division Group, Temasek Life Sciences Laboratory, Singapore, Singapore

The actomyosin contractile ring, a multi-protein structure that contains F-actin, type II myosin and several other proteins, is important for cytokinesis in unicellular and multicellular eukaryotes. In animal cells, this ring is assembled in the plane perpendicular to that of the mitotic spindle long axis upon onset of anaphase. Depending on the cell type, the signals are postulated to come from the spindle midzone containing antiparallel microtubules, the centrosome-organized astral microtubules which interact with the cell cortex, and/or the metaphase chromosomes which contain signaling passenger proteins. Here, we present surprising evidence for the de novo self-assembly of actomyosin rings in anucleate fission yeast cells. Our findings suggest that mechanisms triggering self-assembly of the actomyosin contractile ring can occur independently of components such as spindle midzone, astral microtubules, centrosomes or chromosomes. * P.T. Tran and Y. Huang contributed equally to this work.

**Tracking Actin Dynamics with Quantum Dots during Contractile Ring Assembly**

W. Chen, D. Zhang; Zoology/CGRB, Oregon State University, Corvallis, OR

The contractile ring assembles during late anaphase and remains highly dynamic as it constricts the cell during cytokinesis. Although both newly-polymerized actin filaments and pre-existing actin cables may contribute to the ring dynamics, it is unclear whether these actin filaments are static or dynamic as they assemble into the ring. To address this question, we co-labeled actin filaments in insect spermatocytes by microinjection with trace amounts of Alexa 488 phalloidin and Qdot 655 phalloidin conjugates. As Qdot 655 phalloidin intermittently decorates actin filaments, it forms quantum dot speckles along the length of Alexa 488 phalloidin-stained actin filaments. Being highly-resistant to photobleaching, these bright Qdot speckles provide precise reference points for analyses of shortening or elongation of an actin filament and its movement relative to other filaments or cellular constituents during cytokinesis. Our results show that during late anaphase and early telophase, stable actin filaments move towards the equatorial cortex, aligning into V-shaped cortical structures around the cell equator. As cytokinesis proceeds, the V-shaped actin filaments merge into a belt of parallel actin bundles perpendicular to the spindle axis. It appears that *de novo* assembly of actin filaments also contributes to the enrichment of actin filaments in the contractile ring, as some speckles incorporate into the ring independent of preexisting actin filaments. This approach may permit the tracking of actin dynamics during other cellular events and in other cell types which involve studying the assembly and contraction of the actomyosin based contractile system.

889

**Actin Cross-linking Protein α-actinin Regulates Cell Cleavage during Cytokinesis in Tissue Cultured Cells**

S. A. Mukhina,[1] Y. Wang,[2] M. Murata-Hori[1]; [1]Temasek Life Sciences Laboratory, Singapore, Singapore, [2]University of Massacusetts Medical School, Worcester, MA

Cytokinesis is a spatially and temporally regulated event crucial for cell proliferation. Despite much attention, it is still unclear how cytokinesis is regulated. Due to the existence of strong cortical forces and the concentration of actin filaments and myosin II along the equator, it is principally

believed that an equatorial contractile ring generates forces to produce two daughter cells. However, the regulation of cell cleavage appears to be more complex, and may involve modulation of actin filament structures. Thus, to understand the detailed mechanism of the cell cleavage, it is important to identify the functions of actin modulating proteins at a high spatial and temporal resolution. In this study, we analyzed the detailed functions of an actin cross-linking protein α-actinin during cytokinesis in tissue cultured cells. Using GFP technology, we found that α-actinin accumulated along the equator underwent gradual dissipation as cytokinesis progressed. Overexpression of α-actinin induced excessive bundling of actin filaments in the equatorial region, which frequently led to cytokinesis failure. To the contrary, depletion of α-actinin by siRNA promoted collapse of the equatorial cortex and caused accelerated cell cleavage. In order to investigate if depletion of α-actinin along the cleavage furrow facilitated cytokinesis, we performed local inactivation of α-actinin at one side of the cleavage furrow by chromophore assisted laser inactivation. Strikingly, the laser-irradiated side of the equator developed a deep furrow while irradiation of GFP alone did not affect cytokinesis, supporting the idea that inactivation of α-actinin at the equator facilitates cytokinesis. Our results strongly suggest that cytokinesis involves the regulation of actin filaments cross-linking by α-actinin at the equator.

890

**Actin Crosslinking and Severing Controls Cytokinesis Contractility Dynamics and Intercellular Bridge Separation**

E. M. Reichl, D. N. Robinson; Cell Biology, Johns Hopkins University, Baltimore, MD

Cytokinesis is the mechanical separation of a cell into two daughter cells. A genetic screen to isolate factors that inhibited cytokinesis was carried out by using a cDNA overexpression library in *Dictyostelium discoideum.* An actin isoform, the actin polymerization regulator VASP, and the actin crosslinkers p34 and fimbrin were identified in the screen. Because the fimbrin overexpression phenotype was highly penetrant, we chose to investigate it in more detail and to contrast it with the actin filament severing protein cofilin. Both fimbrin and cofilin are required for wild type bridge morphology and cytokinesis efficiency. Interestingly, the mutant morphology of cells with increased fimbrin levels differed, depending on whether myosin II was present, and the phenotype of the *myosin II*: *fimbrin OE* cytokinesis may be best explained by considering the fluid dynamics of cytokinesis. In summary, the cell appears to finely regulate the mechanics of the actin cortex to achieve efficient, stereotypical cytokinesis.

891

**Testing the Role of Astral Microtubules in Contractile Ring Assembly**

L. I. Strickland, K. Johanson, D. R. Burgess; Biology, Boston College, Chestnut Hill, MA

Astral microtubules (MTs) communicate with the cell cortex during anaphase in echinoderm eggs to stimulate the assembly of the contractile ring for cytokinesis. The polar relaxation model asserts that astral MTs relieve tension at the polar cortex, resulting in contraction at the equator where tension remains high. The equatorial stimulation model proposes that MTs emanating toward the equator promote contractility of the equatorial cortex. We report a series of experiments to determine whether astral MTs exert a positive or negative influence on the contractility of the cortex in dividing sea urchin eggs. We used local application of nocodazole (NZ) to locally depolymerize astral MTs at one pole or the equator at the time of MT-cortical contact. We used a GFP-tagged F-actin binding domain of the eutrophin protein to visualize the contractile ring. When NZ was applied locally with a micropipette to one pole, ring assembly was displaced toward the opposite pole by an average of 5 um. NZ released the polar astral MTs from their attachment to the polar cortex at the site of application. However, the position of the mitotic apparatus relative to the opposite pole was not affected by NZ application so that the displacement of the contractile ring resulted in a cleavage furrow that initiated off center relative to segregating chromosomes. As cytokinesis progressed, the contractile ring centered by sliding across the cell toward the NZ treated pole, resulting in two daughter cells of equal volume. When NZ was applied to the equatorial cortex on one side, furrowing was delayed or blocked at the site of application but not at the opposite side resulting in a unilateral furrow. These results support the equatorial stimulation model and are not consistent with the polar relaxation model for cytokinesis.

892

**Microtubules Regulate Organization and Dynamics of Actin during Cytokinesis**

K. T. Murthy, C. J. Fagerstrom, P. Wadsworth; Biology Department, University of Massachusetts, Amherst, Amherst, MA

During cytokinesis, an F-actin and myosin II containing contractile ring assembles at the equatorial cortex and functions to divide the cell into two daughter cells. Microtubules of the mitotic spindle specify the site of contractile ring formation, but the mechanism by which this is accomplished is not known. To gain insight into how microtubules contribute to actin organization and dynamics during cytokinesis, we imaged GFP-actin in control cells and in cells treated with 33uM nocodazole to diassemble microtubules. Cells that were treated with nocodozole immediately after anaphase onset were blocked in cytokinesis with no distinct actin accumulation at the equatorial cortex. When cells were treated with nocodazole approximately one minute after anaphase onset, cytokinesis continued, although more slowly than control cells. In these cells, the contractile ring was dramatically increased in width and actin was observed to move toward and accumulate at the equatorial region. Under these conditions the microtubules were rapidly disassembled, although a subset of central spindle microtubules were differentially stable. In all nocodazole treated cells, GFP-actin organization was perturbed; actin was observed to accumulate in non-equatorial regions of the cortex and in some cases wave-like cortical contractions were observed. Active myosin light chain, identified by staining with antibody to phosphorylated myosin light chain, was observed at the contractile ring in control cells, but was missing in nocodozole treated cells. FRAP experiments in nocodozole treated cells demonstrate that actin remained highly dynamic in cells that continued to cleave, but turnover was suppressed in cells that were blocked in cytokinesis. Our results demonstrate that microtubules direct actin flow towards the equator during cytokinesis and prevent actin accumulation in other regions of the cortex. In addition, microtubules dictate the width of the contractile ring.

893

**Cdc42 Stabilizes Microtubules Along the Equatorial Cortex During Cytokinesis**

X. Zhu,[1] C. Foong,[1] S. Ahmed,[2] M. Murata-Hori[1]; [1]Mammalian Cell Biology, Temasek Life Sciences Laboratory, Singapore, Singapore, [2]Neural Stem Cell Laboratory, Institute of Bioengineering, National University of Singapore, Singapore, Singapore

Cytokinesis is a fundamental process essential for cell proliferation. In animal cells, the anaphase spindle has been implicated in the stimulation of

cytokinesis. Recent analyses of microtubules and microtubule binding proteins in the anaphase spindle suggest that the stabilized microtubules along the equator are involved in the regulation of cytokinesis. However, how the microtubules along the equator are stabilized and how the stabilized microtubules stimulate cytokinesis remain unanswered. An attractive candidate molecule regulating these processes is the small GTPase Cdc42. Since Cdc42 is involved in cytokinesis and in the regulation of microtubules in cell migration and polarity, we speculated that Cdc42 might regulate microtubules during cytokinesis. To address this hypothesis, we constructed TAT fused dominant active and negative mutants of Cdc42 and applied them to anaphase NRK cells. Interestingly, we found that the entire cortex appeared to be activated during cytokinesis in the cells treated with dominant active and negative mutants of Cdc42, which frequently led to cytokinesis failure. To analyze the dynamics of microtubules in these cells, we applied TAT fused dominant active and negative mutants of Cdc42 to the anaphase NRK cells expressing GFP-tubulin and took time-lapse imaging of microtubules. Kymographic analyses revealed that the astral microtubules became stabilized in the cells treated with dominant active and negative mutants of Cdc42, while dynamic astral microtubules were observed in the control cells. 3D reconstruction revealed the abnormal organization of midzone microtubules in cells treated with dominant active and negative mutants of Cdc42. We also found that dominant active and negative mutants of Cdc42 predominantly accumulated along the equatorial cortex during cytokinesis. Taken together, we suggest that Cdc42 is involved in the stabilization of microtubules along the equator, which may in turn stimulate cytokinesis.

894

### Mechanical Feedback Regulation of Cytokinesis

J. C. Effler,[1] S. Kee,[2] M. Tran,[3] P. A. Iglesias,[1] D. N. Robinson[4]; [1]Electrical and Computer Engineering, Johns Hopkins University, Baltimore, MD, [2]Luther College, Decorah, IA, [3]Elmira College, Elmira, NY, [4]Cell Biology, Johns Hopkins University School of Medicine, Baltimore, MD

Cytokinesis, the physical separation of a mother cell into two daughter cells, is mechanically regulated by various actin-crosslinking and actin-based motor proteins which differentially localize to the polar or cleavage furrow cortex. How cells regulate and control their progression through the various shape changes of cytokinesis in a variety of mechanical environments is not well understood. We postulate that mechanical feedback mechanisms exist which help to govern this process. To test this hypothesis, we apply physiologically relevant mechanical loads to dividing cells at differing stages of cytokinesis and monitor the distribution of fluorescently tagged proteins. Cells in anaphase respond to these loads by recruiting myosin-II and cortexillin to the portion of the cortex where the load is applied. This redistribution allows the cell to escape the pipette. Thereafter, myosin-II and cortexillin are recruited to the cleavage furrow cortex. Neither protein redistributes under equivalent mechanical loads in interphase cells. Through these experiments we have begun to uncover how cells transduce mechanical signals to regulate cellular shape.

895

### Probing Cytoplasmic Structures and Forces in Animal Cells during Cytokinesis

T. Iwasaki, Y. Wang; University of Massachusetts Medical School, Worcester, MA

Biochemical, cell biological, and genetical studies have provided clues on many aspects of the mechanism of cytokinesis. However, little is known about mechanical environment of the cytoplasm in dividing cells beyond what was demonstrated decades ago using flexible microneedles. To detect the distribution of forces, we injected high molecular weight, linear polyacrylamide (PAA) into NRK cells and monitored their shape and movements. PAA in interphase cells appeared as scattered, tangled aggregates with irregular shapes. However, when the cell entered prometaphase, PAA aggregates coalesced into a small number of spheres as if there were an increase in the structure of the surrounding cytoplasm, possibly due to an increase in the density, stability, or rigidity of the cytoskeleton that excludes PAA. In contrast, PAA in interphase cells rounded up by trypsin remained as scattered aggregates. Following anaphase onset, PAA aggregates near the equatorial region moved rapidly into the spindle midzone. The pattern of movements, and the insensitivity to cytochalasins, suggested that the movement involved localized weakening of cytoplasmic structures in the interzone rather than pushing forces of the ingressing cortex. Aggregates outside the equatorial region showed no consistent movements during anaphase. These results suggest that, in addition to cortical forces, changes in cytoplasmic structures may play an important role in the shape change, midzone formation, and cleavage process of dividing cells.

896

### Mob1 Associated Proteins and their Roles in Regulating Mitotic Exit and Cytokinesis in Higher Eukaryotes

G. Montano, J. Rashe, L. Weber, C. B. Shuster; Biology, New Mexico State University, Las Cruces, NM

Maintenance of genomic stability requires that chromosome segregation and cytoplasmic partitioning are coordinated with high fidelity. However, the molecular mechanism by which this occurs in metazoan cells remains unclear. In yeast, Mob1 (Mps-One Binding) protein participates in coordinating mitosis and cytokinesis by serving as an activating subunit for the Dbf2/Sid2 kinases. Mob1 and Dbf2/Sid2 localize to the spindle poles up until anaphase, at which time they re-localize to the actomyosin ring during cytokinesis. In an effort to determine whether Mob1 plays a similar role in higher eukaryotes, we used the yeast two-hybrid (Y2H) system to identify Mob1A binding proteins in human cells. Using human Mob1A as bait, Large Tumor Supressor 2 (Lats2) kinase was identified from a pretransformed Hela cell cDNA library that demonstrated a strong two hybrid interaction. Lats1 and Lats2 share homology with the Dbf2/Sid2 kinases, but there has been no data to date demonstrating that either binds Mob1. Mutant alleles of yeast Mob1 have been described that inhibit Dbf2/Sid2 binding and cause cytokinesis defects *in vivo*, and alteration of these positions in human Mob1A abolished human Lats2 binding. In humans, there are 4 different isoforms of Mob1 (A-D), and preliminary studies indicate that hLats2 preferentially associates with Mob1A. From these studies, it is our hypothesis that Lats2 is the Dbf2/Sid2 homologue in higher eukaryotes, and further studies *in vitro* and *in vivo* will determine whether this is, indeed, the case.

897

### Ace2p Contributes to Fission Yeast Septin Ring Assembly by Regulating *mid2*$^+$ Expression

C. S. Petit, S. Mehta, R. H. Roberts, K. L. Gould; Cell and Developmental Biology, Vanderbilt University, Nasvhille, TN

The fission yeast *Schizosaccharomyces pombe* divides through constriction of an actomyosin-based contractile ring followed by formation and degradation of a medial septum. Formation of an organized septin ring is also important for the completion of *S. pombe* cell division and this event relies on the production of Mid2p. *mid2*$^+$ mRNA and protein accumulate in mitosis. Recent microarray analyses identified *mid2*$^+$ as a target of the Ace2p transcription factor, and *ace2*$^+$ as a target of the Sep1p transcription factor. We report here that Mid2p production is controlled directly by

Ace2p functioning downstream of Sep1p. As expected then, both Sep1p and Ace2p are required for septin ring assembly and genetic analyses indicate that septin rings function in parallel with other Ace2p targets to achieve efficient cell division. Conversely, forced overproduction of Sep1p or Ace2p prevents septin ring disassembly. We find that Ace2p levels peak during anaphase and Ace2p is post-translationally modified by phosphorylation and ubiquitination. Ace2p localizes symmetrically to dividing nuclei and functions independently of the septation initiation network. In future studies, we plan to investigate the role of Ace2p phosphorylation in its regulation.

## Actin-Associated Proteins II (898-918)

### Loss of Profilin Confers Tumorigenic Characteristics to Mammary Epithelial Cells

L. Zou,[1] P. Roy[2]; [1]Bioengineering, University of Pittsburgh, Pittsburgh, PA, [2]Bioengineering and Pathology, University of Pittsburgh, Pittsburgh, PA

**Objective:** Profilin has been implied as a tumor suppressor protein based on downregulation of its expression in mammary tumor cells and its ability to reduce tumorigenicity and migration of breast carcinoma when overexpressed in these cells. However, a direct functional relevance of reduced expression of profilin in tumor progression has not been established. The goal of the present work was to determine whether reduced profilin expression confers tumorigenic characteristics to mammary epithelial cells. **Methods:** A small-interfering RNA (siRNA) was used to silence profilin expression in human mammary epithelial cells (HMEC), while the control cells were transfected with a non-targeting oligonucleotide that has no significant sequence homology with any known mouse or human gene. The effects of downregulation of profilin on HMEC proliferation, adhesion and intercellular junctions were determined. **Results:** Nearly 90% reduction in profilin expression was achieved in HMEC by RNA interference. Immunostaining of vinculin showed a dramatic decrease in the number of focal adhesions in HMEC as a result of silencing of profilin. From the immunostaining of beta-catenin, loss of cell-cell junctions was also evident in the siRNA-treated cells. Finally, silencing profilin resulted in approximately two-fold increase in cell proliferation. **Conclusion:** Since loss of cell-cell and cell-matrix adhesions, and increased cell-proliferation are hallmarks for neoplastic transformation, our results for the first time suggest that suppression of profilin expression may actually be functionally linked to the pathogenesis of breast cancer.

899

### Functional Characterization of Profilin in the Migration of Breast Cancer Cells

V. R. Panchapakesa,[1] P. Roy[2]; [1]Bioengineering, University of Pittsburgh, Pittsburgh, PA, [2]Bioengineering and Pathology, University of Pittsburgh, Pittsburgh, PA

**Objective:** We have previously shown that overexpression of profilin reduces the migration of invasive breast cancer cells. Besides actin, profilin also binds to several proline-rich motif (PRM) proteins that are important for cytoskeletal reorganization. The aim of the present work is to determine whether profilin's interactions with PRM proteins are important for the migration of breast carcinoma. **Methods:** We have generated cell lines of MDA-MB-231 that stably express GFP-fused constructs of either profilin or its mutant form (H133S) that is unable to bind to PRM proteins. GFP-expressing cells served as negative control. **Results:** Expression of H133S mutant prevented endogenous profilin's interaction with actin and thus acted as a dominant negative. Transwell migration experiments demonstrated that expression of both profilin and its H133S mutant reduced EGF-directed chemotactic migration of MDA-MB-231 with higher suppression in cell migration achieved when profilin was overexpressed. Timelapse microscopy revealed that H133S mutant cells were able to produce multiple cell protrusions, which however lacked any directional bias, and hence resulted in minimal net cell translocation. Defect in cell translocation was also observed in profilin overexpresser cells. Increased formation of actin filaments and focal adhesions were also evident in these two types of cell lines. **Conclusion:** These results imply that 1) profilin-PRM interactions may be important for directional and spatial regulation of cell protrusion, and 2) profilin-induced suppression of MDA-MB-231 migration may result from excessive actin polymerization and increase in cell adhesion.

### Regulation of Actin Dynamics by Direct Interaction Between Profilin and Srv2/CAP

E. A. Bertling, P. K. Mattila, P. Lappalainen; University of Helsinki, Institute of Biotechnology, Helsinki, Finland

The actin cytoskeleton is regulated by a large number of proteins that interact with monomeric and/or filamentous actin. Cyclase-associated-proteins (CAPs) are highly conserved actin monomer-binding proteins that are found in all eukaryotes examined so far. Yeast CAP (also called Srv2/CAP) is a 58 kDa protein consisting of a highly conserved C-terminal ADP-actin binding domain and an N-terminal regulatory domain. In addition, the C-terminal domain of Srv2/CAP contains two proline-rich regions, which have been suggested to bind profilin and/or SH3 domain proteins. We carried out a biochemical analysis of the C-terminal half of yeast Srv2/CAP (amino acids 253-526) to examine the possible interaction with profilin and to elucidate how this interaction alters actin-binding properties of these proteins. GST pull-down and tryptophan fluorescense assays revealed that Srv2/CAP indeed binds profilin with a Kd of 1.3 uM. Site-directed mutagenesis analysis demonstrated that the first proline-rich region (P1) of Srv2/CAP is essential for profilin-binding, whereas the second proline-rich region (P2) does not contribute to interactions with profilin. Our fluorometric binding assays also demonstrated that profilin-binding to Srv2/CAP does not interfere with actin-interactions of Srv2/CAP, suggesting that these proteins can form a ternary complex consisting of Srv2/CAP, profilin, and two actin monomers. In our mutagenesis studies, we also identified one Srv2/CAP allele that interacts with ADP-actin monomers with normal affinity but has strong defects in profilin-binding. We are currently examining the biological role of profilin-Srv2/CAP interaction by analyzing the effects of this mutant Srv2/CAP when expressed in yeast instead of wild-type protein.

901

### Silencing Profilin Stabilizes Intercellular Junctions of Vascular Endothelial Cells

Z. Ding,[1] P. Roy[2]; [1]Bioengineering, University of Pittsburgh, Pittsburgh, PA, [2]Bioengineering and Pathology, University of Pittsburgh, Pittsburgh, PA

**Objective:** Vascular hyper-permeability as a result of compromised integrity of intercellular junctions of endothelial cells (EC) contributes to

pathogenesis of many life-threatening disorders. Permeability mediators stimulate assembly of actin stress fibers (SF) and formation of focal adhesions (FA) in EC. These steps requiring actin polymerization are critical for generating transcellular contractility, which is partly responsible for junctional disruption and loss of EC barrier function. As profilin is thought to be an important catalyst of actin polymerization, we examined whether silencing profilin improves the junctional stability of EC. **Methods:** A small interfering RNA (siRNA) was used to silence profilin expression in human umbilical vein endothelial cells (HUVEC), while the control cells were transfected with a non-targeting oligonucleotide that has no significant sequence homology with any known mouse or human gene. **Results:** Nearly 100% silencing of profilin expression was achieved in EC by RNA interference. Immunostaining of ZO-1, VE-cadherin and beta-catenin revealed that EC after siRNA treatment became resistant to junctional disruption in response to VEGF treatment. An increase in VE-cadherin expression was observed in siRNA expressing cells. Furthermore, silencing profilin prevented VEGF-induced assembly of actin SF and FA in EC. Finally, data from wound-healing experiments showed that suppression of profilin significantly inhibited EC migration, an event that also widens the gap between neighboring EC during vascular hyper-permeability. **Conclusions:** Taken together, these results suggest that silencing profilin may be an effective strategy to reduce endothelial permeability.

902

### Two Mouse Cofilin Isoforms, Muscle-type (MCF) and Non-muscle Type (NMCF), interact with F-actin by Different Efficiency

K. Nakashima,[1] N. Sato,[1] T. Nakagaki,[1] H. Abe,[1] S. Ono,[2] T. Obinata[1]; [1]Department of Biology, Chiba University, Chiba-shi, Japan, [2]Department of Pathology, Emory University, Atlanta, GA

Two cofilin isoforms, muscle-type (MCF) and nonmuscle-type (NMCF), are co-expressed in developing mammalian skeletal and cardiac muscles. MCF is expressed more abundantly in slow skeletal muscle than in fast skeletal muscle. To clarify how they are involved in actin filament dynamics during myofibril assemly, we examined their localization in muscle tissues and cultured muscle cells by immunocytochemical methods with the antibodies specific for MCF or NMCF and their interaction with F-actin in vitro. NMCF was detected mostly in a diffused pattern in the cytoplasm but MCF was partly localized to the striated structures in myofibrils. Location of chicken cofilin, a homologue of MCF, in I-bands of myofibrils was determined by an immunocytochemical method. The results suggest that MCF is associated with actin filaments in muscle cells more efficiently than NMCF. Using purified recombinant MCF and NMCF, their interaction with F-actin was examined in vitro by cosedimentation assay. We observed that MCF was precipitated with F-actin more effectively than NMCF. When MCF and NMCF were simultaneously incubated with F-actin, MCF was preferentially associated with F-actin. MCF and NMCF inhibited interaction of F-actin with tropomyosin, but the former suppressed the actin-tropomyosin interaction more strongly than the latter. These results suggest that MCF interacts with F-actin with higher affinity than NMCF, and although both of them are involved in the regulation of actin assembly in developing myotubes, the two proteins may play somewhat different roles

903

### Cofilin and Phalloidin Co-rescue Filament Formation in Polymerization-deficient Actin Mutant

A. Shvetsov,[1] V. Galkin,[2] A. Orlova,[2] M. Phillips,[1] P. Rubenstein,[3] E. Egelman,[2] E. Reisler[1]; [1]Department of Chemistry and Biochemistry and Molecular Biology Institute, UCLA, Los Angeles, CA, [2]Department of Biochemistry and Mol. Genetics, University of V.A. Jordan Hall, Charlottesvile, VA, [3]Department of Biochemistry, University of Iowa College of Medicine, Iowa City, IA

Previous studies demonstrated that cofilin, which is essential for actin filament turnover in vivo, changes the helical twist and weakens longitudinal and lateral contacts in F-actin. Phalloidin stabilizes these lateral and longitudinal contacts and competes with cofilin for the binding to F-actin. Using yeast actin triple mutant, L180C/L269C/C374A, we showed previously that locking the hydrophobic loop to G-actin surface by a disulfide bridge prevents filament formation. Neither phalloidin nor cofilin alone can induce the polymerization of this actin. Myosin subfragment 1 is equally inefficient in this task. Here, we show that together cofilin and phalloidin co-rescue the polymerization ability of the polymerization-deficient cross-linked actin. EM revealed a dense contact between opposite strands in F-actin, suggesting cofilin-phalloidin-induced conformational changes in actin protomers that support interstrand interactions. EM analysis showed that cofilin changes the helical twist of the disulfide cross-linked actin filaments from 166 to 165 degrees, indicating either partial or disordered attachment of cofilin to F-actin and/or a competition between cofilin and phalloidin to alter F-actin symmetry. We propose that there are regions of F-actin primarily occupied with cofilin, which bridges between longitudinal protomers, followed by regions where phalloidin stabilizes lateral and longitudinal contacts.

904

### Role of the Actin Binding Protein Cofilin/Adf in Cell Migration and Mouse Development

W. Witke, C. Gurniak, G. Bellenchi, E. Perlas; Mouse Biology Unit, EMBL, Monterotondo, Italy

Cofilin and ADF belong to the family of F-actin depolymerizing factors thought to be essential for regulating actin polymerization and directed cell migration. Unlike lower eukaryotes, three cofilin/ADF genes are found in the mouse - non-muscle cofilin (n-cofilin), muscle cofilin (m-cofilin) and ADF. We have generated mouse models for n-cofilin and ADF applying conventional as well as conditional mutagenesis. Using these mouse models as well as cells cultured from the respective mutants we have been able to distill specific roles of the depolymerizing factors in cell migration, proliferation and cell cycle control. Recent results on n-cofilin/ADF function in different tissues and cell types using cre-lox mediated deletion will be discussed.

### *Salmonella* SipC Nucleates Actin to Promote Bacterial Entry

J. Chang, J. Chen, D. Zhou; Biological Sciences, Purdue University, West Lafayette, IN

*Salmonella* type III secreted SipC possesses dual effector translocation and actin-modulating functions. The biological significance of SipC's actin nucleation activity in *Salmonella*-induced actin cytoskeleton rearrangements and bacterial invasion has not been studied. We report here the delineation of the actin nucleation activity from its effector translocation activity. Our data showed that the central amino acid 201-220 region is essential for its actin nucleation activity and the amino acid 321-409 region is required for its effector translocation activity. A SipC nucleation deficient mutant, which maintained its effector translocation activity, was obtained. This nucleation-deficient mutant had significantly reduced

ability to induce actin cytoskeleton rearrangements resulting in lower bacterial invasion into HeLa cells. Contrary to previous report, we found that the purified recombinant wild type $SipC_{199-409}$ protein is monomeric in solution by size exclusion chromatography coupled with multiangle laser light scattering assays (SEC-LS). Our data established that the actin nucleation activity of SipC plays a vital role in *Salmonella*-induced membrane ruffles and subsequent bacteria invasion.

**Cortical and Gap Junction Distribution of Human Titin Carboxyl Terminus and Co-localization With Actin**

J. Qi,[1] L. Chi,[1] A. J. Banes[2,1]; [1]Flexcell International Corporation, Hillsborough, NC, [2]Department of Biomedical Engineering, Curriculum in Applied and Material Sciences, University of North Carolina, Chapel Hill, NC

**Introduction** - Titin, as a major structural protein in sarcomeres, interacts with many of sarcomeric proteins such as myosin, actin, α-actinin, titin-cap (telethonin), calpain, obscurin and MURFs. Most of these proteins, except MURFs which were linked to M-band of titin, bind to Z-band of titin. Few titin partner proteins were located in the carboxyl (C-) terminus of titin. Since titin was also reported to express in non-muscle tissues and cells, its distribution in these tissues and cells will contribute to the fully understanding the functions of titin. In this study, we investigated the intracellular localization of C-terminal titin (M7-10) in COS-7 cells and its interaction with cytoskeletal proteins. **Methods** - The human C-terminal titin cDNA was amplified from total human skeletal muscle cDNA and cloned into pcDNA3 vector. The construct was transfected into COS-7 using lipofectamine. The transiently expressed titin C-terminal fragments were stained with anti-titin rabbit polyclonal antibody M8M9 which recognizes titin C-terminal M8-M9 domains. The stained C-terminal titin was visulized with goat anti-rabbit IgG Alexa 568. Actin fibers were co-stained with BODIPY FL-phallacidin. **Results** - The result showed cortical and gap junction distribution of the C-terminal titin fragments heterogenously expressed in COS-7 cells and co-localized with actin. The immunostaining of mock-transfected COS-7 cells with M8M9 antibody did not reveal any endogenous signal, this confirmed the linkage between C-terminal titin fragments and actin. **Conclusion** - The results in this study indicate that actin may bind to titin in its C terminus directly or indirectly through adaptor proteins. This finding will facilitate the understanding the cellular functions of titin in non-muscle tissues and cells.

907

**The Formation of GFP-Tagged Hirano Bodies in *Dictyostelium discoideum* After Inducible Expression of a Truncated Actin Bundling Protein**

J. F. Reyes, A. G. Maselli; Biological Sciences, Chicago State University, Chicago, IL

Neurodegenerative disease such as Alzheimer's disease and Pick's disease have been associated with unique protein aggregates including neurofibrillary tangles, Lewy bodies and amyloid plaques, but little attention has been given to Hirano Bodies (HB). Hirano Bodies are rod-like cytoplasmic inclusions of actin and actin associated proteins. The formation of Hirano bodies has been shown to occur in *Dictyostelium discoideum* after expression of a truncated form of the 34-kDa actin bundling protein, providing a unique opportunity to study protein aggregation in living cells. We have developed a system to monitor the formation of HB using a vector with inducible promoter activity. The ribonucleotide reductase promoter (Gaudet et. al. 2001) is a strong inducible promoter with an activity lasting 3 hours post induction. To visualize the formation of Hirano Bodies, Green Fluorescent Protein (GFP) was fused to the carboxyl terminal end of the truncated form of the 34-kDa protein. Here, we report a 35-fold increase in the presence of GFP-tagged, rhodamine phalloidin positive cytoplasmic inclusions after promoter induction with UV light. Our results suggest that a short pulse of promoter activity produces sufficient protein to begin the formation of Hirano Bodies. The inclusions observed by GFP vary considerably but the average area is 5.7 $\mu m^2$ , SD ± 11.6 $\mu m^2$ in the induced populations. The measurements were obtained 15 hours post induction when the inclusions formed can be easily observed. Using this inducible system will allow us to further study Hirano Bodies and characterize the kinetics and their fate within living cells.

908

**The G35 Antigen Appears to be a Form of α-actinin Which Co-isolates and Co-localizes with Type III Intermediate Filaments**

A. Abedi, D. M. García, J. R. Koke; Department of Biology, Texas State University-San Marcos, San Marcos, TX

Monoclonal antibody G3.5 was raised against multiple sclerotic plaque material from human brain and spinal cord. The antigen of this antibody has been previously designated an α-actinin-like protein with the unusual features of localizing separately from skeletal muscle α-actinin, localizing with desmin in muscle and with GFAP in astrocytes, and simultaneously binding actin and desmin *in vitro*. The physical properties of the antigen are essentially identical to the published properties of α-actinin, and initial amino acid sequencing showed a high degree of identity to sarcomeric α-actinin. Attempts to use amino acid sequence data to isolate a unique gene sequence for the G3.5 antigen have failed. Recent studies have demonstrated that α-actinin has a more complex role in cellular structure and development than previously thought. α-actinin has been shown to be subject to tyrosine kinase phosphorylation and associate with many proteins in addition to actin. Because of this new information, we reisolated the G3.5 antigen from rat skeletal muscle as before, using a modified desmin isolation protocol. The G3.5 antigen was then released and separated from the insoluble desmin fraction by addition of a reducing agent and centrifugation. Limited proteolysis and sequencing of the G3.5 antigen has provided 7 fragments totaling 72 residues, 98.6% identical in sequence to regions found in rat sarcomeric α-actinin. Immunohistochemical analysis of the G3.5 antigen was also performed and produced results similar to those described above. The preponderance of evidence therefore suggests that either the G3.5 antigen is a novel form of α-actinin that associates with type III intermediate filaments as well as actin, or that the mAB G3.5 reveals a previously undescribed association or binding site on type II α-actinin for type III IFs.

909

**Palladin Binds Directly to F-actin and Crosslinks Actin Filaments**

A. S. Rachlin,[1] M. J. Costello,[2] C. A. Otey[1]; [1]Cell and Molecular Physiology, University of North Carolina, Chapel Hill, NC, [2]Cell and Developmental Biology, University of North Carolina, Chapel Hill, NC

Palladin is a multi-isoform protein that localizes to actin-rich structures, including stress fibers, focal adhesions, cell-cell junctions and the Z-line of cardiac myocytes. Palladin's role as a cytoskeletal scaffold is supported by an emerging list of cytoskeletal proteins with which it interacts. This group includes the f-actin crosslinking protein alpha-actinin, VASP and profilin, proteins with well-defined roles in actin polymerization and the

protein Lasp-1, which plays an important role in cellular motility. All of the above mentioned proteins have been shown to directly bind filamentous and/or monomeric actin. The overexpression of palladin in a variety of cultured cells induces the formation of unusually large, hyper-bundled stress fibers. We set out to determine if these bundles are generated indirectly, as the result of palladin's interactions with its binding partners, or if palladin may have direct effects on f-actin organization. To address this question, baculovirus expressed palladin was purified and a co-sedimentation assay was used to determine if palladin binds directly to f-actin. When palladin was mixed with skeletal muscle actin in a 1:10 molar ratio, the bulk of palladin co-fractionated with f-actin. In addition, purified palladin was found to crosslink individual actin filaments into bundles, as observed by fluorescence microscopy and differential centrifugation. Palladin induced actin bundles were further analyzed using transmission electron microscopy. These results suggest that the overexpression phenotype of actin bundling is due in part to palladin's own independent crosslinking activity and suggest a role for palladin in the contractile machinery of the cell. Taken together, the evidence to date indicates that palladin is both an actin cross-linking protein and a scaffold for the recruitment of other actin-binding proteins of widely varying activities, suggesting that palladin may occupy an unusual functional niche in regulating actin assembly in cells.

910

**Biochemical Studies on Mouse Inverted Formin 2 (INF2)**

E. Seth Chhabra, H. N. Higgs; Biochemistry, Dartmouth Medical School, Hanover, NH

**Background:** Formins are a conserved class of eukaryotic proteins which regulate actin dynamics. There are seven metazoans formin groups, which include 15 mammalian formin genes. These proteins are characterized by the presence of FH1 and FH2 (formin homology 1 and 2) domains. Inverted Formins (INF) are members of a recently identified unique formin group which is present in metazoans only. The FH1 and 2 domains in these formins are present at the N-terminus while in all other formin groups these domains are at the C- terminus. **Objective:** We are examining the biochemical effects of mouse inverted formin 2 (INF2) on actin polymerization dynamics. **Results:** An N- terminal construct (INF2-N), containing FH1 and 2 domains, possesses properties similar to those of other formins, including: nucleation acceleration; elongation inhibition (90% inhibited); profilin- mediated relief of elongation inhibition; and antagonism of complete barbed end capping by heterodimeric capping protein. A C-terminal construct binds one actin monomer, mediated most likely by a WH2 motif, resulting in monomer sequestration. Full length protein (INF2-Full) has surprising properties. While it accelerates assembly of actin filaments from ATP-monomers, it also causes disassembly of actin filaments when phosphate release is not inhibited. This dual activity leads to biphasic polymerization dynamics, with initial filament assembly followed by disassembly, and has possible cellular implications. **Conclusion:** The dual assembly/ disassembly properties of INF2 provide interesting possibilities for cellular regulation of actin dynamics.

911

**Glutathionylation of Mammalian β,γ-F-actin Enhances its Interaction with Human Cofilin**

L. A. Selden,[1] R. L. Finkle,[1] J. S. Dengler,[1] H. J. Kinosian,[1] L. C. Gershman,[1] J. E. Estes[1,2]; [1]Research Service, Stratton VA Medical Center, Albany, NY, [2]Center for Cell Biology and Cancer Research, Albany Medical College, Albany, NY

Cytoskeletal rearrangements accompany the cellular response to oxidative stress and involve the actin binding protein cofilin. Reversible glutathionylation of actin may play a role in modulating this response. We have used F-actin containing a small amount (≤ 10%) of pyrene-labeled actin to monitor the binding of human cofilin to mammalian β,γ-nonmuscle actin. The pyrene-actin fluorescence is quenched by cofilin binding, but the actin subunits containing pyrene cannot be glutathionylated due to the presence of pyrene at the glutathionylation site (cysteine 373). Thus, differences between control and glutathionylated actin represent changes in the pyrene-actin environment rather than a direct effect of glutathionylation on the actin subunit. Working at pH 6.5 and low concentrations of F-actin (0.5 μM) and cofilin (1 μM), we found that pyrene fluorescence quenching by cofilin was slow and incomplete for control samples. Glutathionylation of the actin increased the initial rate of quenching by nearly 50-fold. Removal of the glutathione from the actin with DTT restored the quenching rate to that of the control. These data suggest that the reversible glutathionylation of actin can modulate the binding of cofilin to actin and may contribute to the rearrangement of the actin cytoskeleton in response to oxidative stress. Supported by the Department of Veterans Affairs.

912

**Fascin1-deficient Mice Show Neurological Defects**

Y. Yamakita, S. Yamashiro; MBB, Rutgers Univ., Piscataway, NJ

Fascin is an actin-bundling protein, and is believed to be involved in the assembly of actin bundles in filopodia. Vertebrates have three fascin genes (fascin1-3). While expression of fascin2 and fascin3 is strictly restricted to retina and testis, respectively, fascin1 is more ubiquitously expressed and particularly abundant in cells with well-developed filopodia such as neuronal cells. Because filopodia are critical for cell motility and/or interactions with other cells, fascin1 has been suggested to play roles in growth cone motility and guidance of neuronal cells. To explore these possibilities, we generated fascin1 knockout (KO) mice. Disruption of fascin1 gene was confirmed by southern blotting, as well as PCR-based genotyping and Western blotting. RT-PCR analyses revealed that other fascin gene products (fascin2 and fascin3) did not compensate fascin1 expression. While fascin1-deficient mice were viable and fertile, they showed neurological defects, as judged from the following phenotypes: First, tail suspension tests conducted with 3 months or older mice revealed that fascin1 KO mice held their limbs into their bodies (so-called "huggers" phenotype) whereas wild-type mice spread their limbs. Second, more than 50% of fascin1-deficient mice showed spontaneous seizures. Nissl staining of coronal brain sections revealed that the posterior of anterior commissure neurons was mostly lacking in fascin1 KO mice, suggesting that fascin1 deficiency may affect extension of anterior commissure neurons. We also examined, using dorsal root ganglionic neurons (DRGNs), whether fascin1 deficiency affects growth cone morphology and neurite outgrowth. We found that DRGNs from either fascin1 KO or wild-type mice were able to extend neurites. However, the size of growth cones of fascin1-deficient DRGNs is smaller and filopodia are less in number and shorter in length. Our results suggest that vertebrate fascin1 affects growth cone dynamics and is critical for proper formation of neuronal networks.

913

**The Actin Filament Crosslinker Fascin 2 Localizes to the Inner Segment Actin Filament Bundles of Photoreceptors**

J. Lin-Jones, B. Burnside; Molecular and Cell Biology, University of California - Berkeley, Berkeley, CA

Fascin 2 is an actin-filament cross-linker that is expressed exclusively in the retina. Fascin 2 is important for the maintenance of functional photoreceptors as a human mutation in fascin 2 results in autosomal dominant retinitis pigmentosa and macular degeneration. While fascin 2 has been localized to photoreceptors in the retina, its exact subcellular localization has not been determined. The purpose of this study is to examine in more detail the location of fascin 2 in vertebrate photoreceptors. We have cloned fascin 2 cDNA from Xenopus and zebrafish retinal libraries and used bacterial fusion proteins to Xenopus and zebrafish fascin 2's to generate antibodies. In addition, Xenopus fascin 2 fused to green fluorescent protein has been expressed in rod photoreceptors in transgenic Xenopus tadpoles to examine the subcellular localization of fascin 2 in rods. Results from both immunohistochemistry and transgenic tadpoles using fluorescence microscopy demonstrate that fascin 2 is localized to inner segment actin filament bundles and calycal processes that encircle the proximal outer segment of photoreceptors. Thus, the data suggest that fascin 2 plays an important role in maintaining the structural actin cytoskeleton of photoreceptors by affecting the actin filament bundles of the photoreceptor inner segment.

914

**Characterization of Drebrin-A: A Spine Specific Actin-bundling Protein Which Competitively Binds to F-actin with Tropomyosin and Caldesmon**

R. Ishikawa, A. Takahashi, Y. Hanyuda, A. Nakamura, K. Kohama; Department of Pharmacology, Gunma University School of Medicine, Maebashi, Japan

Drebrin is an actin-binding protein specifically expressed in brain. Two types of isoforms, embryonic type (drebrin-E), and adult type (drebrin-A) are produced from a single gene by alternative splicing. Drebrin-A localizes in dendritic spine of mature neuron, and suggested to affect spine morphology. In this report, we successfully purified drebrin-A by using bacterial expression system, and characterized in vitro. Drebrin-A bound to actin filaments with a stoichiometry of 4 actin molecules to 1 drebrin-A molecule. It inhibited the actin-binding activity of caldesmon by 70%. This inhibitory effect was enhanced in the presence of tropomyosin. Furthermore, caldesmon coupled with tropomyosin inhibited the actin-binding of drebrin, indicating that drebrin competitively binds to F-actin with tropomyosin and caldesmon. Low speed centrifugation assay revealed that drebrin-A had actin-crosslinking activity, which were confirmed by direct visualization of fluorescently labeled F-actin complexed with drebrin-A. These results suggest that caldesmon coupled with tropomyosin may affects spine morphology through regulating drebrin-A activity.

915

**Regulation of Villin-Induced Cell Migration by Lysophosphatidic Acid**

A. Tomar,[1] S. George,[1] N. Kumar,[1] I. G. Macara,[2] S. Khurana[1]; [1]Physiology, University of TN, Memphis, TN, [2]Center for Cell Signalling, University of Virginia, Charlottesville, VA

Villin is an epithelial cell-specific protein that nucleates, severs, caps and cross-links actin filaments. The actin-modifying activities of villin are regulated in vitro by calcium, phosphoinositides and tyrosine phosphorylation. In this study, we demonstrate for the first time the association of villin with lysophosphatidic acid (LPA). LPA binds to previously identified phosphatidylinositol 4,5-bisphosphate binding sites in villin, however the two ligands have opposite effects on the actin modifying activities of villin. The direct association of LPA with villin inhibits actin-capping, -severing, -polymerizing and -bundling activities of villin but enhances c-src mediated tyrosine phosphorylation of villin. In contrast, the direct association of villin with $PIP_2$ enhances the actin-bundling activity of villin and inhibits c-src mediated tyrosine phosphorylation of villin. Using time-lapse video microscopy, MDCK Tet-Off cells transfected with yellow fluorescent tagged villin protein (SEYFP-villin), we show that LPA enhances cell migration and the formation and growth of lamellipodia in cells overexpressing SEYFP-villin. This was accompanied by the redistribution of villin to the leading edge. LPA-induced cell migration in these cells is completely inhibited by the PLC inhibitor U-73122 but not its inactive analog U-73144 nor by the $G\alpha_i$ inhibitor, pertusis toxin. MDCK cells express the LPA receptor, LPA2. Our hypothesis is that LPA can modulate villin-induced cell migration either by directly associating with villin (intracellular regulation) or by activation of G protein-coupled receptor LPA2. Phospholipids like LPA can be safely added to a regular diet and their levels can be modulated by various pharmacological agents leading us to speculate that LPA-regulated intestinal cell migration by villin can have therapeutic benefits.

916

**Expression of Full-length Smooth Muscle Myosin Light Chain Kinase**

A. Nakamura,[1] K. Kawano,[1] Y. Gao,[2] Y. Hanyuda,[1] A. Takahashi,[1] R. Ishikawa,[1] K. Kohama[1]; [1]Department of Molecular and Cellular Pharmacology, Gunma University Graduate School of Medicine, Maebashi, Japan, [2]Department of Biochemistry and Molecular Biology, Dalian Medical University, Dalian, China

Myosin light chain kinase (MLCK), family of calmodulin-dependent protein kinases, catalyzes the phosphorylation of regulatory light chain (MLc 20) of myosin, and plays an important role in activating actomyosin-linked contractility in smooth muscle cell[1)2)]. In spite of the trial to express full-length MLCK by various expression systems, it has not been successful yet. So, we tried to make a recombinant bovine stomach MLCK (BsMLCK) by using a new bacterial expression system, which was developed by Prof. Masayori Inouye of Robert Wood Johnson Medical School[3)]. We succeeded in the high level expression (5-10mg/L culture medium) of full-length BsMLCK by using the cold shock bacterial expression system. Recombinant BsMLCK was a soluble form and phosphorylated MLc20. It also had actin-binding and -bundling activities. Recombinant BsMLCK with the properties known for the MLCK was expressed in the large amount, which should be the first step to analyze the structure and function of MLCK. [References] 1. **Ezrin Is Activated by PKC and Contributes to Metastatic Phenotype of Osteosarcoma Cells**

L. Ren, S. Hong, J. Cassavaugh, C. Khanna; Pediatric Oncology Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD

Osteosarcoma (OSA) is the most common primary tumor of bone. Despite successful control of the primary tumor and adjuvant chemotherapy,

death from pulmonary metastases occurs in over 30% of patients within 5 years. Using a genomic approach we identified ezrin, a membrane-actin cytoskeleton linker protein, to be over-expressed in the more aggressive K7M2 murine OSA model compared to the less aggressive K12 model. In vivo studies in this murine model demonstrated that ezrin protein and ezrin function were necessary for metastasis. Furthermore, studies in child-hood OSA patients suggested that high primary tumor expression of ezrin was associated with a shortened disease free interval compared to patients with low primary tumor expression ($p<0.01$). Phosphorylation of C-terminal threonine 567 on ezrin is believed to be important for ezrin activation. The kinase responsible for ezrin activation at this C-terminal threonine in vivo and particularly during metastasis of cancer is not known. Using pharmacological inhibitors we found that phosphorylation of ezrin at T567 was dependent on PKC (BIM, Ro31-8220, Go6976) but not by inhibition of Rho-kinase (Y27632) or PI3 Kinase (LY294002). To investigate the role of PKC and ezrin in regulation of tumor metastasis, wound closure (cell migration) assays were performed using K7M2 cells. Cell migration was inhibited by both PKC inhibitor Go6976 and through the antisense suppression of ezrin. Studies are underway to determine if PKC controled cell migration is mediated through or dependent on ezrin.

### Deregulated RhoA Signaling is Detrimental to Arp2 mRNA Localization

L. A. Mingle, G. Liu; Cell Biology & Cancer Research, Albany Medical College, Albany, NY

The Arp2/3 complex, a nucleator of actin polymerization, is localized to the leading edge of migrating cells. The mRNAs for the subunits of the complex also localize to the leading protrusions of fibroblasts, suggesting that mRNA localization may mediate the protein complex localization. The localization of Arp2 mRNA, one subunit of the complex, is dependent on external stimuli. However, the signal transduction mechanisms mediating this localization remain unknown. Here we present evidence that a signaling pathway utilizing RhoA is important for Arp2 mRNA localization. Using chicken embryo fibroblasts (CEFs), we show that Arp2 mRNA localizes to the leading protrusions in CEFs in response to platelet derived growth factor (PDGF-BB) and basic fibroblast growth factor (bFGF) stimulation. However, neither activators nor inhibitors for Protein kinase C (PKC) or Protein kinase A (PKA) could significantly alter the Arp2 mRNA localization, suggesting that PKC and PKA are not involved in Arp2 mRNA localization under these conditions. In contrast, Rho kinase (ROCK) is required for Arp2 mRNA localization, as pretreatment with Y-27632 significantly inhibits serum induced Arp2 mRNA localization. Interestingly, Arp2 mRNA localization is also inhibited by the constitutive activation of R-Ras and RhoA. Constitutive activation of either R-Ras or Rho has no effect on β-actin mRNA localization, suggesting that Arp2 mRNA localization may utilize a unique mechanism. These data suggest that Rho signaling is necessary for Arp2 mRNA localization, but that too much or too little RhoA activity is detrimental to the localization. We are currently testing if RhoA needs to be spatially regulated for Arp2 mRNA to localize to the leading protrusion.

## Actin Dynamics & Assembly I (919-938)

919

### A Primary Role for the Second SH3 Domain of the Eukaryotic Adaptor Protein Nck in Actin Assembly Induced by Enteropathogenic *E coli*

P. J. Savage, L. Magoun, J. M. Leong; Molecular Genetics and Microbiology, University of Massachusetts Medical School, Worcester, MA

Upon infection of the human intestine, enteropathogenic E. coli (EPEC), reorganizes the host cell cytoskeleton to generate filamentous actin-rich structures, known as pedestals, beneath the sites of bacterial attachment. To trigger actin assembly, EPEC translocates the bacterial protein Tir into the host cell, where it is clustered at the plasma membrane and phosphorylated at tyrosine residue 474. The Tir sequence encompassing phosphorylated Y474 recruits Nck, a eukaryotic adaptor protein comprised of three SH3 domains and one SH2 domain, to initiate actin pedestal formation in an N-WASP-dependent fashion. Latex beads coated with a twelve amino acid Tir peptide containing phosphorylated Y474 recruit Nck and stimulate localized actin assembly in cell-free extracts. To determine which domains of Nck are critical for function, we tested Nck deletion derivatives for the ability to promote actin assembly around latex beads coated with Tir peptide in cell-free mammalian extracts. As expected, the C-terminal SH2 domain, which binds the Tir phosphopeptide, was essential for function. In addition, a fragment carrying the second and third SH3 domains of Nck, in conjunction with the SH2 domain, was able to promote actin assembly in vitro. The lack of a role for the first SH3 domain was confirmed by complementation of pedestal formation by Nck-deficient cells with Nck deletion derivatives. In fact, whereas a Nck derivative carrying the SH2 and the third SH3 domains promoted only moderate levels of assembly, an analogous fusion carrying the SH2 and the second SH3 domains restored pedestal formation to wild-type levels. These results indicate that of the three SH3 domains of Nck, only the second SH3 domain plays an essential role in EPEC-induced actin assembly.

920

### Molecular Characterization of the T maritima MreB

G. J. Bean,[1] J. A. Mayer,[2] L. Hazelwood,[3] D. Anjum,[3] D. Hanein,[3] K. J. Amann[4]; [1]Molecular Biology, UW-Madison, Madison, WI, [2]Cell and Molecular Biology Program, UW-Madison, Madison, WI, [3]Burnham Institute, La Jolla, CA, [4]Zoology / Molecular Biology, UW-Madison, Madison, WI

Bacterial actin homologues play critical roles in the determination of cell shape and DNA segregation. Little is currently known about the biochemical functions of these molecules, including their capacities for polymerization dynamics and intermolecular interactions. We are studying these properties of several prokaryotic actin homologues with the intention of explaining the manner in which the bacterial cytoskeleton carries out its physiological role. We have expressed in *E. coli* and purifed the actin homologue MreB from the thermophile *T. maritima.* As measured by light scattering and sedimentation, MreB polymerizes in the presence of divalent cations, as do eukaryotic actins. It binds ATP and rapidly hydrolyzes it rapidly following polymerization. In many ways, however, MreB exhibits unexpected properties for an actin homologue. Its polymerization is highly sensitive to pH, ionic strength, and temperature changes. The products of polymerization can be sedimented at much lower centrifugal forces than can individual actin filaments. By electron microscopy, at least two different structures can be produced by manipulation polymerization conditions: very thin, short stubs; and tube-like structures that are reminiscent of microtubules. We suggest that MreB nucleation and polymerization mechanisms are highly distinct from those of eukaryotic actins and that their physiological functions are likely to differ greatly as well.

921

**Molecular Mechanism of Rickettsia Actin-Based Motility**

R. L. Jeng,[1] E. D. Goley,[1] J. A. D'Alessio,[1] T. M. Svitkina,[2] O. Y. Chaga,[3] R. A. Heinzen,[4] G. G. Borisy,[3] M. D. Welch[1]; [1]Dept. of Molecular and Cell Biology, UC Berkeley, Berkeley, CA, [2]Dept. of Biology, University of Pennsylvania, Philadelphia, PA, [3]Dept. of Cell and Molecular Biology, Northwestern University Medical School, Chicago, IL, [4]Laboratory of Intracellular Parasites, NIAID, NIH, Rocky Mountain Laboratories, Hamilton, MT

Spotted fever group *Rickettsia* are obligate intracellular pathogens that cause a range of diseases such as Rocky Mountain spotted fever. During infection, bacteria exploit the host-cell actin cytoskeleton to promote entry, motility, and cell-to-cell spread, but little is known about the molecular components involved in these processes. Several observations suggest that the underlying mechanisms behind *Rickettsia* motility differ from those involved in the motility of other pathogens such as the well-studied *Listeria monocytogenes*. In particular, *L. monocytogenes* generates actin comet tails containing branched filaments using an Arp2/3 complex-dependent mechanism while *Rickettsia* generates comet tails consisting of unbranched filament arrays that lack the Arp2/3 complex. To better understand the molecular mechanism of *Rickettsia* motility, we identified a candidate nucleating factor called RickA that exhibits sequence similarity to the WASP-family of proteins. RickA is similar to other WASP-family proteins in its ability to stimulate the nucleation and branching activities of the Arp2/3 complex *in vitro*. When coated on the surface of micrsospheres, RickA is also sufficient to promote motility and generate comet tails in cell-free extracts. However, we found that RickA is localized to the bacterial cytoplasm rather than at the cell surface where an actin nucleator would be expected to function. Furthermore, by itself, RickA generates branched filament arrays. These results suggest that, while RickA may be integral to actin nucleation at the surface of *Rickettsia*, other factors are likely to be involved in the nucleation and organization of filaments. To identify some of these factors, we examined two candidate proteins that appear to be involved in organizing actin filaments in *Rickettsia* comet tails: the actin bundling protein, fascin, and an F-actin binding protein, VASP. Both proteins localize to *Rickettsia* tails, and we are currently testing their contribution to *Rickettsia* motility using RNA-interference techniques.

922

**Interaction Between Prokaryotic Actin ParM and the R1-plasmid Kinetechore Complex ParR/parC: Force Generation, Polarity, and Insertional Polymerization**

E. C. Garner,[1] H. G. Garcia,[2] L. Coin,[2] L. Trichet,[2] D. R. Mullins[1]; [1]Biochemistry, UCSF, San Francisco, CA, [2]Physiology course, Marine Biological Labs, Woods Hole, MA

The R1 par operon is thought to construct a minimal DNA-segregating spindle from three components, the centromeric DNA sequence parC, the DNA binding protein ParR, and the actin homolog ParM. In vivo, the ParR/C complex is thought to couple ParM polymerization to plasmid segregation. In vitro, ParM filaments exhibit rapid spontaneous nucleation, symmetrical elongation, and dynamic instability. Using Total Internal Reflection Fluorescence (TIRF) microscopy, we show that the ParR/parC complex stabilizes individual ParM filaments against catastrophic depolymerization. ParR/parC-mediated stabilization produces a population of long filaments that grow asymmetrically with one fast-growing and one slow-growing end. The fast-growing end elongates by insertion of ParM monomers at the interface with ParR/parC. To demonstrate that the connection between ParM and the ParR/parC complex is capable of generating force, we coupled ParR/parC complexes to micron-sized polystyrene spheres and incubated them with ParM in the presence of non-hydrolyzable nucleotides. Assembly of ParM filaments occurs preferentially at the surface of the microsphere and filaments are rapidly organized into an asymmetrical bundle. Elongation of filaments at the interface with ParR/parC generates force propelling the microshpere through the medium. By polarization microscopy the filaments in the bundle are aligned parallel to the direction of motion. By confocal fluorescence microscopy the bundle has a hollow core. Based on these results, we propose a model for assembly and function of a DNA-segregating ParM spindle.

923

**In vivo Dynamics of the Bacterial Actin ParM**

C. S. Campbell, D. Mullins; University of California San Francisco, San Francisco, CA

The R1 Par operon is a self-contained plasmid partitioning system composed of three parts: *parC*, ParR and ParM. *parC* is a stretch of DNA consisting of 10 sequential repeats, each of which binds ParR. The ParR/*parC* complex in turn binds the actin homolog ParM. Previous studies have shown that ParM forms filaments nearly identical to those of eukaryotic actin filaments and that ParM filament bundles appear to position plasmids at each end of a rod-shaped cell. We recently demonstrated that ParM filaments are dynamically unstable and can elongate bidirectionally *in vitro*. These observations led to a model in which ParM filaments continually search the cytoplasm and eventually capture a ParR bound *parC* region on a plasmid. Insertional polymerization at the ParM/ParR interface will then push the plasmids to opposite ends of the cell and hold them in place until cell division, ensuring that each daughter cell receives a copy. To test this model directly in live cells, we used RFP labeled lacI to visualize lacO sites present on a plasmid containing a functional R1 Par operon and GFP labeled ParM to visualize the filaments directly at the same time. We find that ParM filaments are dynamically unstable in vivo and that the majority of filaments undergo assembly and rapid disassembly in less than a minute. In addition, the filaments appear to orient themselves along the long axis of a bacterium by running into the sides of the cell and then following them to the poles. The most striking result, however, is that the plasmids undergo continual and very rapid pole-to-pole movements even when not actively dividing. Our results indicate that plasmid partitioning by ParM is a very dynamic process and suggest a new model for polymer-based plasmid segregation.

924

**Functional Mapping of Arp2/3 Complex and NPF Residues Involved in Complex Activation**

A. D. Siripala, E. D. Goley, E. Znameroski, M. D. Welch; Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA

The Arp2/3 complex integrates binding of several different activating factors to promote actin nucleation and filament branching. Arp2/3 complex activity requires binding to actin and nucleation-promoting factors (NPFs), but the precise molecular interactions involved in complex remain unclear. To identify sites of interaction with binding partners and gain insight into the molecular mechanism of Arp2/3 complex activation, we have performed site-directed mutagenesis on conserved Arp2/3 complex surface residues. We have identified several mutations in putative NPF binding

regions of Arp2 and Arp3 that reduce nucleation activity of the complex. Additionally, we have generated a series of mutations in the Arp2/3 binding domain of the NPF WASP to identify complimentary residues critical for Arp2/3 binding and activation. Those Arp2/3 and WASP mutations found to abrogate nucleation activity are being tested for their effects on binding affinity using fluorescence anisotropy. We will then compare the effect of these mutations on NPF affinity with their effects on Arp2/3 conformation, measured using fluorescence resonance energy transfer (FRET). By this method we can determine whether NPF binding, conformational change, and activation are mediated by the same residues, or whether they are separable activities. To address the role of mother filament binding in Arp2/3 complex activity, we have generated mutations in surface residues of the p34 and p20 subunits, and have found that they cause a range of defects in nucleation. At least one of these mutations causes a decrease in F-actin binding. By developing a more detailed picture of the molecular interactions and conformational changes required for Arp2/3 activation, we hope to better understand the complex process by which multiple factors come together to promote regulated actin polymerization in the cell.

925

**Identification and Biochemical Characterization of Small Molecule Arp2/3 Complex Inhibitors**

N. Tomasevic, A. Russell, D. Pierce, Z. Jia, R. Sakowicz; Cytokinetics Inc., South San Francisco, CA

Dynamic rearrangements of the actin cytoskeleton underpin a variety of essential cellular processes like migration, polarization or endocytosis and are also used by cellular pathogens (e.g., Listeria). A key component of the cellular actin polymerization machinery is the seven subunit Arp2/3 complex, responsible for nucleation and branching of nascent actin filaments. We devised an actin-polymerization based high throughput screen for modulators of Arp2/3 complex activity, hoping to uncover pharmacological tools that would further understanding of the many physiological functions of the Arp2/3 complex. The screen found two distinct classes of Arp2/3 complex inhibitors represented by compounds CK-0944636 and CK-0993548. Both compounds are potent (<10uM) and specific Arp2/3 complex inhibitors, as observed in either WASP or ActA stimulated actin polymerization assays. Neither compound inhibited spontaneous or formin-nucleated actin polymerization at concentrations up to 100uM. Exposure to CK-0944636 significantly reduced the total amount of Arp2/3 nucleated actin polymer, producing sparse but highly branched actin structures. In contrast, the presence of CK-0993548 did not significantly affect the total amount of actin filament produced, but the resulting filaments were primarily linear with minimal branching. Both compounds inhibited Arp2/3 complex dependent cellular processes such as podosome formation and Listeria motility. Availability of specific Arp2/3 complex inhibitors provides the cell biology community with important tools for studying the dynamics and physiology of the actin cytoskeleton.

926

**Mechanism of Actin Nucleation and Branching by Arp2/3 Complex and Coronin**

K. M. Daugherty, M. Gandhi, B. L. Goode; Rosenstiel Basic Medical Sciences Research Center, Brandeis University, Waltham, MA

The mechanism by which Arp2/3 complex nucleates and branches actin filaments remains poorly understood. When activated by WASp or other proteins, the Arp2/3 complex can nucleate new (daughter) filaments from the sides of existing (mother) filaments to form branched structures. However, it is unclear whether filament side binding and branching is a requisite for nucleation or instead represents only one form of Arp2/3-dependent nucleation. Further, it is unclear whether branched nucleation by Arp2/3 complex is essential *in vivo* and/or what other cellular factors might regulate branching. To address these issues, we targeted for mutagenesis the essential *S. cerevisiae ARC35* gene, which encodes the ARPC2/p35 subunit of Arp2/3 complex. Previous studies suggest that this subunit plays an important role in both filament side binding and transducing WASp-stimulated conformational changes to the complex. We integrated alanine substitutions at every conserved solvent exposed residue on p35 and identified surfaces essential for *in vivo* function. We also developed methods for purifying Arp2/3 complex from strains expressing these lethal alleles to assess their biochemical defects in nucleation and branching. We then used these mutants to map the coronin functional interaction surface on p35. Coronin interacts with p35 through its coiled-coil domain and is the only known direct inhibitor of Arp2/3 complex. Coronin stabilizes Arp2/3 complex in an open inactive conformation until filaments are present, which relieves inhibition. In this manner, coronin is thought to spatially restrict Arp2/3-mediated nucleation to the sides of filaments to promote branching. We identified one surface on p35 that suppresses *CRN1* overexpression defects *in vivo* and suppresses coronin inhibitory effects on Arp2/3 complex *in vitro*. The proximity of this surface to essential surfaces that may mediate filament side binding suggests a mechanism by which coronin regulates Arp2/3 activity.

927

**Investigating Arp2/3 Complex and Formins as Assembly Factors for Actin-based Surface Protrusions in Lymphocytes**

S. M. Nicholson-Dykstra, J. Lee, F. Li, H. N. Higgs; Biochemistry, Dartmouth Medical School, Hanover, NH

INTRO: The lymphocyte cell surface is not smooth, but is covered by actin-filament based protrusions. Primary blood lymphocytes possess short microvilli (0.3-0.4 microns long), whereas cultured leukemia or lymphoma lines often exhibit both ruffles and microvilli. Microvilli are hypothesized to play roles in surface receptor segregation which is necessary for extravasation (transit from blood to periphery). OBJECTIVE: Our objective is to determine the mechanisms of microvillar and ruffle assembly in lymphocytes. Two attractive assembly factors are Arp2/3 complex and the formin family proteins. METHODS: Utilize “dominant-negative” inhibition and RNAi-based protein suppression to determine roles of actin nucleators in surface protrusion formation. Additionally, utilize antibodies to determine protein localization and abundance. RESULTS: Our current evidence using a function-blocking construct (GFP-fusion of N-WASP CA region) suggests that Arp2/3 complex is not required for microvillar assembly in lymphocytes. We have identified seven formins in lymphocytes that exhibit appreciable mRNA levels, four of which also exhibit appreciable protein quantities. Currently, we are analyzing protein localization and functional significance of these formins. CONCLUSIONS: 1) Lymphocyte microvilli assemble through an Arp2/3 complex-independent mechanism; 2) A subset of formins is likely to act in surface protrusion assembly in un-activated lymphocytes.

928

**Pure Native WAVE2 Complex Is Tightly Inhibited and Cannot be Activated *In Vitro* by Rac or Nck**

A. M. Lebensohn, M. W. Kirschner; Department of Systems Biology, Harvard Medical School, Boston, MA

WAVE proteins are central regulators of Arp2/3 mediated actin assembly downstream of the small GTPase Rac. In cells WAVE forms a tight

heteropentameric complex, which plays a crucial role in regulating WAVE function. Two conflicting models describing the details of this regulation have been proposed. One model, based on *in vitro* experiments with native WAVE1 complex, poses that the complex is basally inhibited but can be activated by Rac and/or Nck. The second model, based on *in vivo* localization experiments and *in vitro* assays with recombinant reconstituted WAVE complexes, argues that the complex is basally active and that binding to activated Rac only serves to localize the active complex to sites of actin assembly. Based on *in vitro* studies with native WAVE2 complex we present findings at odds with both models. We found that pure native WAVE2 complex is basally inactive in actin polymerization assays containing Arp2/3 and actin. In fact the complex is so tightly inhibited that not even 1% of its expected activity could be detected in these assays. Unexpectedly, activated Rac failed to activate native WAVE2 complex even at extremely high concentrations. Importantly, Rac bound the native complex, including the WAVE2 subunit, in a nucleotide dependent manner. Nck also failed to activate the native WAVE2 complex when added alone or in combination with Rac. Finally, preheating the native WAVE2 complex to 57°C for 10 minutes before diluting it into the assay resulted in strong Arp2/3 dependent actin nucleation. Thus, native WAVE2 complex is tightly inhibited in its basal state but can be activated *in vitro*, albeit by extreme unphysiological conditions, to promote actin assembly. The physiological mechanism of WAVE complex activation remains unknown.

930

**The Nck-Interacting Kinase Increases Actin Nucleation Rates by Direct Phosphorylation of the Arp2/3 complex**

L. L. LeClaire,[1] M. Baumgartner,[2] R. D. Mullins,[3] D. L. Barber[1]; [1]Cell and Tissue Biology, University of California, San Francisco, San Francisco, CA, [2]Institut of Medical Virology, University of Zurich, Gloriastr, Switzerland, [3]Cell and Molecular Pharmacology, University of California, San Francisco, San Francisco, CA

The Arp2/3 complex is the major nucleator of actin filaments. By regulating the nucleation activity of the Arp2/3 complex, cells maintain precise control over actin polymerization and cytoskeleton assembly. The primary regulators of Arp2/3 complex nucleation activity are nucleation promoting factors of the WASP/Scar protein family. We propose, however, that phosphorylation is an additional mechanism for regulating activity the Arp2/3 complex. In MTLn3 rat epithelial carcinoma cells epidermal growth factor induces a rapid increase in phosphorylation of the Arp2/3 complex within 30 seconds, corresponding with an increase in total cellular F-actin. In vitro, phosphorylation of the Arp2/3 complex by Nck-interacting kinase (NIK) increases actin nucleation rates by 30%. In addition, NIK binds the Arp2/3 complex, and we identified the Arp2/3 binding site between amino acids 360 and 500 of the NIK regulatory domain. By using mass spectrometry we identified two phosphorylated threonine residues in the Arp2 subunit. These residues are located on subdomain 4 of Arp2 and are directly adjacent to arginine residues on the p20 subunit. These threonine and arginine residues are conserved in amino acid sequences from yeast, mice, and humans. By examining structural models of the Arp2/3 complex, we predict a model whereby phosphorylation of the Arp2 subunit facilitates a conformational change with the p20/p35 subunits. A phosphorylation-induced conformational change could enhance Arp2/3 activation by aligning the Arp2 and Arp3 subunits to form a nucleus for a new actin filament, thus providing a previously unrecognized mechanism for Arp2/3 complex regulation. Supported by NIH grants T32 DE07204 to LLL and GM47413 to DLB.

931

**Investigation of the Role of Nucleotide Binding to Arp2/3 Complex using X-ray Crystallography and Molecular Dynamics Simulations**

B. J. Nolen,[1] R. Littlefield,[2] P. Dalhaimer,[1] H. Chen,[1] T. Pollard[1]; [1]Molecular, Cellular and Developmental Biology, Yale University, New Haven, CT, [2]The Scripps Research Institute, La Jolla, CA

Arp2/3 complex stimulates formation of actin filaments at the leading edge of motile cells. The activity of the complex requires binding of ATP by both actin-related subunits in the complex, Arp2 and Arp3, and hydrolysis of ATP by Arp2. We have solved crystal structures of Arp2/3 complex with ATP or ADP both by soaking the nucleotides into preformed crystals and by co-crystallization. Co-complexes obtained through either method have nearly identical structures. In both cases, the nucleotides are immobilized on the face of subdomains 3 and 4 of Arp2, while subdomains 1 and 2 are flexible and absent from the electron density maps, as in the apoenzyme structure. This flexibility may explain why Arp2 does not hydrolyze ATP until the complex is activated. We have recently found that treating crystals of Arp2/3 complex with the crosslinking reagent gluteraldehyde decreases flexibility in the disordered regions of Arp2 and has allowed us to build additional regions of subdomain 1. In either soaked or co-crystallized complexes, ATP stabilizes a relatively closed conformation of Arp3 with the γ-phosphate bridging loops from opposite sides of the cleft. ADP-soaked crystals show that the nucleotide binds Arp3 in a unique conformation which favors an open cleft, revealing a conformational change that may occur in actin and Arps when the γ-phosphate dissociates from the ADP-Pi intermediate. Surprisingly, when ADP is co-crystallized with the complex, Arp3 has a closed cleft and the nucleotide does not exhibit an unusual conformation. We are currently using molecular dynamics simulations to investigate the relationship between nucleotide binding state and conformation in both Arp3 and actin.

932

**The Function of Arp2/3 Complex ATP Hydrolysis**

A. C. Martin, M. Welch, D. G. Drubin; MCB, UC Berkeley, Berkeley, CA

The Arp2/3 complex has been shown to nucleate actin filaments at the leading edge of motile cells and at endocytic sites. However, how the Arp2/3 complex at dendritic branches is released from membrane-bound nucleation promoting factors and how these dendritic branches are disassembled is not fully understood. Given the importance of ATP hydrolysis in actin turnover and the fact that Arp2 ATP hydrolysis occurs after nucleation, ATP hydrolysis by the Arp2/3 complex could regulate these events. Here, we identify an Arp2 mutant in *S. cerevisiae* that is unable to hydrolyze ATP upon nucleation. This mutant shows slightly enhanced nucleation activity *in vitro*, demonstrating that Arp2 ATP hydrolysis is not required for actin nucleation or branch formation. In contrast to other mutations we have identified that elevate Arp2/3 complex nucleation activity, this mutant exhibits severe defects in actin patch/endocytic internalization, suggesting a role for Arp2 ATP hydrolysis in regulating the structure of actin networks. Interestingly, the growth phenotype of this Arp2 hydrolysis mutant is specifically suppressed by loss-of-function mutations in activators of the Arp2/3 complex, suggesting that Arp2 ATP hydrolysis might regulate activator binding. In addition, actin patch disassembly is inhibited in this mutant, suggesting that Arp2 ATP hydrolysis may also regulate the turnover of filamentous actin networks. Interestingly, an equivalent mutation in Arp3 is synthetic lethal with the Arp2 hydrolysis mutant, suggesting that Arp3 ATP hydrolysis may also regulate Arp2/3 complex turnover *in vivo*. These results, along with further biochemical characterization of these mutants, will provide insights into the regulation

of the Arp2/3 complex.

933

**Role of p78/83 and Arp2/3 Complex in Baculovirus Pathogenesis**

E. D. Goley,[1] T. Ohkawa,[2] J. A. D'Alessio,[1] L. E. Volkman,[2] M. D. Welch[1]; [1]Molecular and Cell Biology, University of California-Berkeley, Berkeley, CA, [2]Plant and Microbial Biology, University of California-Berkeley, Berkeley, CA

Of the many pathogens that exploit their host cell's actin cytoskeleton during infection, baculoviruses are remarkable for the unique actin rearrangements they require for replication. Early in infection, baculovirus nucleocapsids induce actin cable formation in the cytoplasm of the host cell, a process hypothesized to mediate efficient translocation to the nucleus, the site of viral replication. Later, baculoviruses induce the polymerization of actin within the nuclei of infected cells, an apparently novel phenomenon that is essential for nucleocapsid assembly. Despite the critical nature of these manipulations of host actin, the molecular mechanisms underlying these changes and the function of actin in progeny production remain unresolved. To investigate the role of actin dynamics during baculovirus infection, we treated cells infected with *Autographa californica* multiple nucleopolyhedrovirus (AcMNPV) with drugs that inhibit actin polymerization or depolymerization and demonstrate that these treatments prevent replication. At the molecular level, we find that an essential and conserved minor capsid protein, p78/83, bears significant homology to the Wiskott-Aldrich Syndrome protein family. We show that p78/83 is a robust nucleation-promoting factor for host Arp2/3 complex, suggesting a mechanism for nucleation of cytoplasmic actin cables that may mediate motility early in infection. Intriguingly, we find that p78/83 and Arp2/3 complex also colocalize with actin filaments in the nucleus later in infection, implicating these factors in the functionally critical nuclear polymerization of actin. Accordingly, mutation of conserved residues in p78/83 causes defects in its ability to activate Arp2/3 complex in vitro. AcMNPV bearing these same mutations are reduced in progeny production, with the worst mutants being unable to sustain virus viability. These data suggest that p78/83 mediates essential actin rearrangements during baculovirus infection by activating host Arp2/3 complex both in the cytoplasm and, strikingly, within the nucleus late in infection.

934

**Microrheology and Stress Fluctuation in Active Gels and Mechanosensitive Cells**

D. Mizuno,[1] R. G. Bacabac,[1] G. Koenderlink,[2] M. Atakhorrami,[1] F. MacKintosh,[1] T. H. Smit,[1] J. Klein-Nulend,[1] C. Schmidt[1]; [1]Vrije University, Amsterdam, The Netherlands, [2]Harvard University, Cambridge, MA

Active processes in cells such as crawling, intracellular transport, and mechanochemial transduction are in many cases related to the function of cytoskeletal networks composed of actin-myosin stress fibers or microtubules, and their associated proteins including motors. Non-thermal stress fluctuation caused by the motor proteins is one of the driving forces of these active processes. Rheological property of the cell (given by cytoskeletal networks) is also a key factor for determining the efficiency or speed of those processes. One intriguing aspect in elucidating cell activity is that the stress fluctuation and the rheological property might be influenced each other. Therefore, in this study, both stress fluctuation and local rheological property was measured simultaneously in mechano-sensitive cells(osteocytes) and in its in-vitro model of actin-myosin gel with ATP. Recently developed techniques called micro-rheology enables us to measure stress fluctuation and local rheological property of biological tissues. Two general approaches in microrheology pertain to measurement of probe-particle displacements embedded in the material investigated. The approach is either by inducing external forces on the probes (active mode) or by monitering the thermal and non-thermal fluctuations of the probes (passive mode). In equilibrium such as actin solution without myosin, active and passive modes gave the same results. However, out of equilibrium, extra stress fluctuation was observed at frequencies lower than 100Hz in both osteocytes and actin-myosin gel. Results were: (1) At 37°C, stress fluctuation of cell has $\omega^{-2}$ frequency dependence. (2) At 20°C, cell loses process with faster fluctuation and hardens its body. (3) At high ATP, non-processive myosin cannot give significant stress fluctuation to actin network. (4) At low ATP, myosin filaments works cooperatively and gives significant stress fluctuation. (5) Non-thermal stress fluctuation can be suppressed by external potential larger than matrix viscoelasticity.

935

**Theoretical Study of Force Generation and Kinetics of Actin Filament Bundles**

D. Vavylonis,[1,2] B. O'Shaughnessy[1]; [1]Chemical Engineering, Columbia University, New York, NY, [2]Molecular, Cellular and Developmental Biology, Yale University, New Haven, CT

Many types of cellular processes are driven by the polymerization and depolymerization of actin filament bundles growing or shrinking against cellular loads. The Brownian ratchet is a mechanistic mathematical model which describes force generation by polymerizing filaments. We used numerical and analytical methods to study the dynamical and equilibrium properties of the Brownian ratchet generalized to the case of stiff actin bundles. For an equilibrium polymerization process (ignoring hydrolysis of ATP bound to actin subunits) the bundle stall force depends linearly on the number of filaments and logarithmically on actin monomer concentration, $c$ (Hill and Kirschner, *Int. Rev. Cytol.* **78**, 1, 1982). The magnitude of time averaged bundle length and force fluctuations at stall is independent of $c$, but we find that the time dependence is strongly dependent on $c$. For high stall forces (high $c$) most filament tips are crowded very close to the load and the collective bundle kinetics are exponentially slow. For small stall forces ($c$ close to $c_{crit}$), the filament length distribution becomes broad leading to fast relaxation. We accounted for ATP hydrolysis by actin using the accepted picture of fast hydrolysis after polymerization followed by slow release of phosphate. We find that the main effects of hydrolysis with respect to equilibrium are (i) a slight change in the stall force and (ii) accelerated dynamics near $c_{crit}$. Formins associated with the filament ends can modify the bundle dynamics. We consider possible mechanisms by which formins can promote fast bundle response even close to stall and high $c$, conditions under which formin-free bundles would elongate slowly. This could be a biologically relevant process since formins localize at the tip of actin bundles in filopodial protrusions.

**In Silico Modeling of Actin Based Motility: Bugs, Beads, Vesicles, and Cell Motility**

J. B. Alberts, G. M. Odell; Center for Cell Dynamics, University of Washington, Friday Harbor, WA

We believe that fully understanding the complex (emergent) behavior of many cellular processes requires mathematical modeling/simulation of the

small-scale biochemical and mechanical details. Such a modeling approach is necessary because the source of the complexity is not often obvious; the dynamics derive from the interplay of thousands of simple interactions with stochastic influences. We thus construct detailed biochemical/mechanical models that are, in essence, computational formalizations of a reductionist view of cellular processes. One example, our "in silico reconstitution" of the motility of the bacteria Listeria monocytogenes is described in Alberts JB & Odell GM, PLoS Biology 2(12). We continue to refine and modify this model, and here apply it to the motility of beads and deformable vesicles. We specifically address the force-velocity relationship, and the effect of geometry on force-generation, for dendritic actin network based motility. In addition we present, as a learning tool, a freely downloadable Java applet that allows for the interactive 3-dimensional exploration of a growing and branching actin network. The user of this program can vary the concentrations proteins (e.g. actin monomer, capping protein, Arp2/3), as well as change the nature of several biochemical interactions, in order to explore the consequence on actin network morphology (e.g. branching frequency, network density).

**Mechanical Properties and Force Generation of Actin Networks near the Polymerization Transition**

A. Pomerance, W. Losert; Institute for Research in Electronics and Applied Physics, University of Maryland, College Park, MD

Gradients in the concentration of actin filaments and in Actin Binding Proteins (ABP) are characteristic of the leading edge of moving cells. Similarly, forces of several pN are characteristically exerted at the leading edge. We present studies of the mechanical properties of actin networks with focus on gradients in network properties and on the response to large forces. In the presence of 2 mM $Mg^{2+}$ and 50 mM $K^{+}$, the critical concentration (CC) for polymerization of actin is 0.03 mg/mL, but in the absence of these ions the CC increases by two orders of magnitude. By studying concentrated actin samples (approximately 3.5 mg/mL) with and without added ions, we compare the behavior near and far above the CC. To study the response to large forces we use holographic laser tweezers to pull microspheres through an actin network. We have found that actin networks far above the CC strongly resist pulling, and have a well-defined relaxation time. Near the CC, beads are easily pulled through the actin networks, and the relaxation is far more variable, which indicates that the actin filaments may be more dynamic and breakable. We generate gradients in actin network structure using a thermal gradient. We observe that in actin networks near the CC, embedded beads are pushed towards the cold side (weaker network) at approximately 0.1 microns/second. This indicates that the flux of energy associated with the thermal gradient may generate forces in a partially polymerized filament network. Gradients in chemical potential, e.g. due to gradients in ABP may also lead to force generation. To study this, we have developed microfluidic devices that maintain a stable, quasi-static gradient in large macromolecules for roughly one hour. Work supported by NIH grant R21BE00328501

**Models and Simulations of Actin Dynamics in Graded Polarity (GP) Bundles**

R. S. Littlefield,[1] C. M. Waterman-Storer,[2] G. M. Odell[1]; [1]Center for Cell Dynamics, Friday Harbor Labs, University of Washington, Friday Harbor, WA, [2]Department of Cell Biology, The Scripps Research Institute, La Jolla, CA

Although contractile actin bundles are important for cell movement, adhesion, and division, it is unknown how actin filament organization is generated during bundle assembly and maintained while they contract. In graded polarity (GP) bundles, the average polarity of actin filaments changes continuously along their length with all barbed ends pointing toward the ends of the bundle, i.e. opposite directions at opposite ends. Using live cell fluorescent speckle microscopy and mathematical models, we investigated the dynamics of actin filaments during the assembly and contraction of GP bundles. De novo GP bundle assembly occurs from the lateral collapse of the lamellar meshwork on the dorsal surface at the lamella-cell body boundary. Actin speckles along GP bundles converge towards each other at a rate of 0.04 - 0.08 percent per minute, but the speckles do not cross each other in kymographs. In contrast, Monte Carlo simulations of GP bundles containing sliding actin filaments predict that speckle tracks would cross. This conflict suggests that actin filaments are dynamically rebuilding the bundle as it contracts to reproduce the speckle behaviors we observe. Indeed, even though the total actin fluorescent intensity remained very stable and uniform along GP bundles, we observed actin speckles flow inward from the ends of GP bundles as well as speckle appearance and disappearance in the middle of GP bundles. We are currently modifying our Monte Carlo simulations to incorporate these observations and determine whether actin filament dynamics can account for GP bundle speckle dynamics. We will also present results from individual-based models which explore how myosin-based contraction and crosslinks by alpha-actinin (which we have observed experimentally) contribute to the movement and dynamics of actin filaments within the GP bundles to produce a stable organization that is able to generate force.

**Mts1 (S100A4) Regulates Cellular Motility via a Direct Interaction with Myosin-IIA**

Z. Li, A. R. Bresnick; Department of Biochemistry, Albert Einstein College of Medicine, Bronx, NY

Mts1, a member of the $Ca^{2+}$-regulated S100 family of proteins, has been characterized as a metastasis factor and is thought to regulate the motility and invasiveness of cancer cells. Previously, we demonstrated that mts1 specifically binds to nonmuscle myosin-IIA on residues 1909-1924 of the heavy chain, and inhibits the assembly of myosin-IIA monomers into filaments and promotes the disassembly of pre-existing myosin-IIA filaments in a calcium-dependent manner. To examine how the biochemical properties of mts1 impact cell motility, we determined how the expression of mts1 affected protrusive behavior during chemoattractant-stimulated motility. In addition, we prepared an antibody to the mts1 binding site on the myosin-IIA heavy chain that has comparable effects on myosin-IIA assembly and motor activity as mts1. Our studies demonstrate that mts1 modulates cellular motility by effecting the orientation and localization of protrusions, with mts1 expressing cells displaying few side protrusions and extensive forward protrusions during chemotaxis as compared to control cells. Microinjection experiments demonstrate that the antibody elicits the same effects on protrusive activity as mts1. These results establish mts1 as a critical regulator of myosin-II mediated motility and suggest that the regulation of myosin-IIA filament assembly is an important regulatory control for cellular motility.

940

**Distinct Roles of Nonmuscle Myosin II Isoforms in The Regulation of MDA-MB 231 Breast Cancer Cell Spreading and Migration**

V. Betapudi, L. Licate, T. T. Egelhoff; Physiology and Biophysics, R# E625A, Case Western Reserve University, Cleveland, OH

Nonmuscle myosin II is an important component of actomyosin cytoskeleton that is believed to play a key role in cell migration in many settings, including cancer metastasis, atherosclerosis, rheumatoid arthritis, wound healing, and angiogenesis. During migration protrusion events at spreading lamellipodia are widely regarded as being driven by F-actin polymerization independent of myosin II, with cell body translocation and posterior contraction generally believed to be myosin II-dependent events. However, the exact mechanical roles of myosin II during cell migration remain remarkably poorly understood. In the present study, we show a transient increase in RLC phosphorylation that correlates the recruitment of myosin IIA and IIB isoforms into distinct periodic rows in the lamellipodia during initial phases of spreading on fibronectin. However, Rho kinase inhibition by using Y-27632 blocks myosin IIA recruitment to lamellipodia with a modest affect on spreading. On the other hand, inhibition of MLCK by using ML-7 dramatically reduced spreading. Depletion of myosin IIA via siRNA impaired migration, but enhanced lamellar spreading, while depletion of myosin IIB impaired not only migration, but also impaired initial rates of lamellar spreading. These results indicate that both isoforms are critical for the mechanics of cell migration, with myosin-IIB appearing to have a specific role in the mechanics of lamellar protrusion events.

941

**Role of Myosin II in Regulating Keratocyte Path Persistence**

E. L. Barnhart, J. A. Theriot; Biochemistry, Stanford University, Stanford, CA

Rapidly locomoting epithelial fish keratocytes display remarkable path persistence, migrating in straight lines even in the absence of any external directional cues. Tracking the cell body centroid of moving keratocytes shows that the cell body oscillates a few microns from side-to-side along a straight path. The regularity of this lateral oscillation suggests that path persistence is maintained by coordination of the rate of protrusion and retraction between the left and right sides of the cell such that any deviation from a straight path is overcorrected. To determine whether lateral oscillation is periodic, we tracked a large population of cells, fit each cell track to a smooth curve, and performed Fourier analysis on the distance between the fit line and the track. All cells exhibited significant periodicity, with periods ranging from 20 to 70 seconds, and there was a strong negative correlation between the period and cell speed. We are presently investigating the mechanism governing this periodic oscillation. To determine whether myosin II contraction at the trailing edge of migrating keratocytes contributes to the oscillation, we transfected cells with a YFP-myosin II regulatory light chain transgene. Live cell imaging of locomoting keratocytes showed that YFP-MRLC accumulates in two pronounced spots on either side of the cell body along the rear edge of the cell. We measured the fluorescent intensity in each of these myosin II rich spots over time and found that they increased in intensity in an anticorrelated periodic fashion. The difference in intensity between the left and right spots was strongly correlated with the position of the cell body, suggesting that myosin II contributes to lateral oscillation. We are currently using a number of inhibitors of myosin II to further characterize its role in cell body oscillation and path persistence.

942

**Dynamic Redistribution of GFP-Myosin II and Traction Forces in Wild-type *Dictyostelium* Movement**

M. Lombardi, D. Knecht, J. Lee; Molecular and Cell Biology, University of Connecticut, Storrs, CT

Cell movement requires the generation of a protrusive force at the leading edge and contractile forces at the cell rear to facilitate retraction. The transmission of contractile forces to the external substratum, via cell adhesions, results in the production of traction forces which “pull” the cell body forward and facilitates retraction at the rear. In our previous studies we investigated traction forces generated by wild-type and myosin II null mutant *Dictyostelium discoideum* cells using a gelatin traction force assay. Our data showed that wild-type cells produced traction forces ten times greater than the myosin II null cells, however the null cells are still capable of generating small traction forces independently of myosin II. In wild-type cells we find that the highest traction forces are located at the rear, while the high traction forces in the null cells are randomly distributed. Another observation in our data is the development of high traction forces just behind the leading edge of a moving wild-type cell that resembled a ‘contractile collar’. To investigate the relationship between traction force production and the location of myosin II we used a GFP-myosin II expressing *Dictyostelium* and the gelatin traction force assay. We observed that GFP-myosin II redistribution does not directly correlate with high traction forces generated by a moving cell. Surprisingly high traction forces at the rear of the cell are shown prior to highly observable aggregated GFP-myosin II. We find that after retraction, traction forces lower while the fluorescence intensity of GFP-myosin II increases. We have also unexpectedly observed that GFP-myosin II is not found in the ‘contractile collar’. Our data suggests that the generation of high traction forces precedes an observable increase in the aggregation of GFP-myosin II in moving *Dictyostelium*.

943

**FRET Analysis Comparing Myosin II Isoforms in Contracting A7r5 Smooth Muscle Cells**

J. E. Black, G. L. Wright; Physiology, Joan C. Edwards School of Medicine, Marshall University, Huntington, WV

Recent evidence has indicated that contraction of A7r5 cells is accompanied by a significant loss in actin stress fiber structure with dissociation of actin and myosin. In the present study we investigated the interaction of the principal isoforms of myosin II (Sm1 and Sm2) with two isoforms of actin, α-actin and β-actin. Whole cell fluorescence resonance energy transfer (FRET) analysis was utilized as an index of the degree of association in control and phorbol-12,13-dibutyrate (PDBu) contracted cells. Average efficiencies indicating association of Sm1 with α-actin were 17 ± 2% in control cells, 10 ± 1% ($p=0.039$) in 0.1μM phorbol contracted cells, and 4 ± 0.9% ($p<0.001$) in 10μM phorbol indicating dissociation of α-actin and this myosin isoform in contracted cells. Similarly, association of Sm1 with β-actin was 18 ± 2%, 12 ± 2%, 5 ± 0.6% ($p<0.0001$), respectively. In marked contrast, there were no significant changes in efficiencies seen when the Sm2 isoform was compared with α-actin or β-actin. This data suggest that the association of Sm1 with actin is altered during contraction; whereas that of Sm2 is constant. We speculate that Sm1 is important in the contraction mechanism while Sm2 is important in maintaining structural integrity role throughout the contraction.

944

**Development of a Mts1 (S100A4) Biosensor to Track Activation In Vivo**

S. C. Garrett,[1] D. Gremyachinskiy,[2] K. M. Hahn,[2] A. R. Bresnick[1]; [1]Biochemistry, Albert Einstein College of Medicine, Bronx, NY, [2]Pharmacology, University of North Carolina at Chapel Hill, Chapel Hill, NC

Myosin-II is highly dynamic as cells undergo directed motility with filament assemblies occurring primarily in lamellae, in the perinuclear region and at the trailing edge. Mts1, a member of the S100 family of proteins, binds specifically to nonmuscle myosin-IIA in a calcium-dependent manner and regulates the monomer-polymer equilibrium of myosin-IIA filaments. To obtain novel information regarding the spatial and temporal activation of mts1 during directed cell motility we developed an mts1 biosensor to report transient or localized calcium binding in vivo. This unique reagent will allow the temporal and spatial distribution of activated mts1 to be examined directly during the motility cycle, and will permit a direct correlation between localized, transient activation of mts1 and the regulation of myosin-IIA assemblies during directed motility. The biosensor was constructed using the novel merocyanine dye ISO-IAA, which displays sensitivity to both solvent polarity and hydrogen bonding, thus small changes in protein conformation can strongly influence the fluorescence properties of the dye. Similar to other S100 proteins, mts1 undergoes a significant conformational change upon calcium binding to the C-terminal EF-hand in which helix 3 extends outward exposing a hydrophobic cleft that forms the target binding surface. The biosensor was generated by the derivatization of a single cysteine residue (C81), proximal to the hydrophobic pocket, with ISO-IAA via a reactive iodoacetamide group. The resulting biosensor displays a 2.4-fold increase in fluorescence intensity upon calcium binding and myosin-IIA binding does not significantly affect the fluorescence intensity of the biosensor. Biochemical analyses demonstrate that the mts1 biosensor has the same binding affinity for calcium and myosin-IIA as the wild-type mts1. Furthermore, in 3T3 fibroblasts the biosensor shows diffuse fluorescence with no sign of aggregation. In vivo studies examining mts1 activation are in progress.

**Myosin II Dynamics in *Dictyostelium* and Mammalian Cells Assessed via GFP-Myosin II Fusions and Fluorescent Recovery After Photobleaching (FRAP)**

M. T. Breckenridge,[1] S. Yumura,[2] M. Yoshida,[2] V. Betapudi,[1] L. S. Licate,[1] Y. Iwadate,[2] A. Nagasaki,[3] T. Q. P. Uyeda,[3] T. T. Egelhoff[1]; [1]Dept Physiol Biophys, Case Western Res Sch Med, Cleveland, OH, [2]Dept Biology, Yamaguchi University, Yamaguchi, Japan, [3]Gene Function Research Center, National Institute of Advanced Industrial Science and Technology, Ibaraki, Japan

Nonmuscle myosin II is a critical player in many cell motility processes, including cell migration, cytokinesis and vesicle trafficking. In vivo this protein exists in a highly dynamic equilibrium between a cytosolic monomer pool and assembled bipolar filaments that associate with the cytoskeleton to produce mechanical force. Mechanisms controlling filament assembly and subcellular localization in vivo remain poorly understood. We present here parallel studies performed with GFP-myosin II fusions in the amoeba Dictyostelium and in human breast cancer cells demonstrating that FRAP analysis can be used to quantify assembly behavior in vivo and to identify mechanisms and upstream kinases regulating assembly in vivo. In Dictyostelium, FRAP analysis performed in candidate myosin heavy chain kinase (MHCK) gene disruption lines demonstrates that three enzymes, MHCK A, B, and C, play a predominant and critical role in regulating the equilibrium between the monomer pool and assembled filament, both in the contractile ring and during interphase. In mammalian cells we find that GFP-myosin IIA and IIB display remarkably rapid turnover between the cytosolic pool and assembled cytoskeletal material, both within the contractile ring and in extending lamellipodia of spreading cells ($t_{1/2}$ for recovery < 1 min). We further demonstrate that myosin IIA and IIB isoforms have distinct assembly/disassembly kinetics, suggesting possible distinct in vivo roles and regulation for these two ubiquitous myosin II isoforms. Further studies are in progress addressing mammalian myosin II isoform assembly regulation in the context of cell migration and spreading, and during cytokinesis.

946

**Reduction of β-Integrin Expression and Cell Attachments in Nonmucle Myosin II-B Null Mouse Embryonic Fibroblasts**

K. Kim, R. S. Adelstein; Lab. of Molecular Cardiology, NHLBI, NIH, Bethesda, MD

Previous work has shown that ablation of nonmuscle myosin heavy chain (NMHC) II-A in mice results in defects in cell adhesion and loss of E-cadherin and β-catenin localization to cell-cell adhesion sites (Conti et al. J. Biol. Chem. 279:41263, 2004). Here we study the function of NMHC II-B in mouse embryonic fibroblasts (MEFs), a cell line that normally contains myosin II-A and II-B, but not II-C. We compared a MEF that was derived from a mouse that had been ablated for NMHC II-B with a MEF derived from a wild-type mouse. The myosin II-B ablated MEFs showed a decrease in the content of both β1 and β3-integrins compared to wild-type using immunoblot and FACS analysis. There was no change in α5 and αv-integrins in these cells. Of note the II-B ablated MEFs showed a decreased attachment to a number of extracellular matrix proteins compared to wild-type MEFs. The defect in both β1-integrin content and cell attachment could be rescued by transfection of II-B ablated MEFs with GFP-II-B. When siRNA to NMHC II-B was used to lower the content of myosin II-B in wild-type MEFs there was a reduction in β1-integrin as well as a decrease in cell-matrix attachment in the siRNA-treated cells. Interestingly, MEFs that contain a mutant myosin II-B (a single amino acid mutation, Cys in place of Arg 709) that has a decreased actin-activated MgATPase activity and *in vitro* motility (Kim et al. J. Biol. Chem. 280:22769, 2005) do not show any abnormality in integrin content or matrix attachment. This implies that myosin motor activity may not be required for β-integrin expression. Our results suggest that NMHC II-B is involved in the attachment of MEFs to the extracellular matrix by regulating β-integrin expression.

947

**Transcriptional Response to Myosin Type II Deficiency in *Saccharomyces cerevisiae***

J. F. Rodriguez-Quinones, F. E. Rivera-Molina, D. Gomez-Garzon, J. R. Rodriguez-Medina; Biochemistry, University of Puerto Rico Medical Sciences Campus, San Juan, Puerto Rico

The *Saccharomyces cerevisiae MYO1* gene encodes myosin type II (Myo1p), a protein related to cytokinesis and cytoplasmic vesicle transport in higher eukaryotes. Myo1p deficiency in yeast (*myo1)* is characterized by altered cell division, cell enlargement, osmotic sensitivity and delocalized chitin deposition, suggesting that it may also be required during cell wall biogenesis. To identify the nature of the cell wall damage caused by

myosin type II deficiency, a transcriptional profile analysis of *myo1* strains was developed using yeast oligonucleotide microarrays. The hybridized arrays were analyzed using statistical methods considering a 2-fold expression change for the mRNA levels of 6,256 known ORFs in the yeast genome. Based on these specifications, 409 up- and 264 down- regulated genes were identified and categorized under cell wall organization and biogenesis, stress response, transport, metabolism, carbohydrate metabolism and protein biosynthesis functions. Certain genes that were up-regulated compared favorably with those previously identified by others in transcriptional analysis of cell wall-related mutations (*PIR3, SPI1, ECM13, ECM4, YGP1*), stress response (*HSP12, DDR2, and YML131W* ) and cell wall damage (*PIR3, HSP12, YHR097C*). Conversely, the reported up-regulation of *SLT2* transcription during transient and chronic cell wall damage was not observed. This study also revealed that despite a requirement for Chs3p expression in *myo1* strains, *CHS3* transcription was not up-regulated. We conclude that *myo1* strains induce a limited subset of genes regulated by the cell wall integrity pathway, but their overall transcriptional response is clearly different from previous studies. This can be attributed to differences in growth conditions used in our study or in the signaling pathways induced by Myo1p deficiency. This work was supported by PHS grants to the University of Puerto Rico, MBRS-SCORE (S06-GM08224) with partial support from RCMI (G12-RR03051) and MBRS-RISE (R25-GM61838).

948

**Conditional Ablation of Nonmuscle Myosin II-B in the Mouse Heart**

A. K. Singh,[1] Q. Wei,[1] K. Takeda,[2] P. Zerfas,[3] C. Birdsall,[1] S. Sidenko,[1] R. S. Adelstein[1]; [1]NHLBI, NIH, Bethesda, MD, [2]NIAID, NIH, Bethesda, MD, [3]OD/ORS, NIH, Bethesda, MD

Ubiquitous ablation of nonmuscle myosin heavy chain II-B (NMHC II-B) in mice resulted in defects in the heart and brain, leading to lethality between embryonic day (E)14.5-E18.5. To understand the physiological role of NMHC II-B in the adult mouse heart, we used a Cre/loxP strategy to ablate NMHC II-B specifically in the heart by generating mice with exon 2 of *Myh 10* flanked by loxP sites. These mice were then crossed with mice expressing Cre-recombinase under control of the α-cardiac MHC promoter, which is activated later in development than the NMHC II-B promoter. In contrast to conventional NMHC II-B ablated mice, 80% of the $B^{\alpha card}/B^{\alpha card}$ mice survived to become adults. These mice developed a novel phenotype beginning at 6 months. EKG abnormalities including bradycardia, right axis deviation and a posterior hemiblock were noted. By 10 months, the echocardiogram of these mice showed a decreased fractional shortening of the left ventricle (21% vs 47% for wild type mice) indicating a compromised cardiac function. Histopathological changes were seen by both light and EM microscopy in these hearts. At 6 months inflammatory cell infiltrates were in the interstitium of all four chambers. By 10 months changes included marked interstitial fibrosis, in which large areas of the myocardium were replaced with connective tissue. Previously, we had shown that NMHC II-B was present in the Z-line and intercalated disks (Takeda et al.,*Cell Motil. Cytoskel.* 2000: **46**, 59). Interestingly, both of these structures were found to be abnormal using EM. Most dramatic were the changes in the intercalated disks, which were markedly widened and distorted compared to wild-type controls. These results show that NMHC II-B, in addition to being required for normal cardiac development, also plays an important role in the adult mouse heart.

949

**Nonmuscle Myosin II-B is Required for Mouse Spinal Cord Development**

X. Ma, J. Bao, S. Kawamoto, C. Liu, R. S. Adelstein; Laboratory of Molecular Cardiology, National Institutes of Health, Bethesda, MD

Ablation of nonmuscle myosin heavy chain II-B (NMHC II-B) or expression of reduced amounts of R709C mutant NMHC II-B results in the development of hydrocephalus as early as embryonic day 13.5 (E13.5) in the mouse. Except for the abnormal protrusion of facial neurons into the developing fourth ventricle, no blockage of the cerebral ventricles is seen in these mice. In spite of this all of the cerebral ventricles are enlarged in the mutant mice compared to wild type mice. We therefore analyzed spinal cord development in various mutant mice including NMHC II-B knockout, R709C II-B mutant hypomorphic and non-hypomorphic mice, as well as mice expressing NMHC II-A in place of II-B. Disruption of the ventricular neuroepithelium was observed by E11.5 in both knockout and R709C mutant hypomorphic mice along the entire spinal cord, and neuroepithelial cells protruded into the developing central canal. Between E13.5- E14.5 the central canal was completely blocked. More severe abnormalities were seen in knockout mice compared to the R709C mutant hypomorphic mice. Interestingly, increased expression of mutant II-B to wild type levels in non-hypomorphic mutant mice prevented blockage of the central canal and development of hydrocephalus, although these mice still suffered from novel abnormalities that were not seen in knockout and hypomorphic mutant mice. When NMHC II-A is expressed in place of II-B, no disruption of the neuroepithelium of the central canal or hydrocephalus was found in NMHC II-B ablated mice. These results indicate that NMHC II-A can replace NMHC II-B in maintaining the integrity of the neuroepithelium in the central canal, although other defects in the brain and heart were not rescued. In conclusion, NMHC II-B plays an important role in maintaining the integrity of the neuroepithelium in the spinal cord.

950

**Transcription Factor Sp3 and DNA Methylation Regulate the Nonmuscle Myosin Heavy Chain II-C Promoter**

M. Chung, R. S. Adelstein, S. Kawamoto; NHLBI, National Institutes of Health, Bethesda, MD

We have previously identified two alternative promoters for the mouse nonmuscle myosin heavy chain (NMHC) II-C gene which are utilized in a tissue-dependent manner. Both promoters lack a TATA box and show a high GC content. The promoter located more distally from the common exon 2 is utilized in a wide variety of tissues in adult mice, with the exception of the lung where the more proximal promoter is predominantly utilized. However, many cell lines derived from these tissues express NMHC II-C mRNAs at very low levels, presumably reflecting the low expression of these mRNAs at early embryonic stages as well as their absence from embryonic stem cells. To explore the mechanisms underlying repression of the distal promoter, we first examined the DNA methylation status of the promoter and flanking regions. Results from analysis of genomic DNA by a methylation-sensitive restriction enzyme, treatment of cell lines with the nonmethylatable analog Aza-C, and analysis of reporter constructs methylated *in vitro* suggest a major contribution of CpG methylation to repression of the distal promoter, but not the proximal promoter. Furthermore, treatment of cell lines with the histone deacetylase inhibitor, trichostatin A (TSA), and to a greater extent with TSA and Aza-C together, leads to activation of the distal promoter activity. Chromatin immunoprecipitation assays, siRNA to Sp1 and Sp3 and overexpression of Sp1 and Sp3 demonstrate that the transcription factor Sp3, but not Sp1, participates in activation of the distal promoter when repression is relieved. These results suggest that DNA methylation and histone deacetylation play critical roles in repression of the distal promoter of the NMHCII-C gene and that Sp3 plays a role in activation of this promoter.

**Increased Expression of the Inserted Myosin II-C Isoform in Tumor Cell Lines**

S. S. Jana, R. S. Adelstein; Laboratory of Molecular Cardiology, National Institutes of Health, Bethesda, MD

A previous report from this laboratory revealed that the newly recognized nonmuscle myosin heavy chain II-C (NMHC II-C) contains an alternative exon composed of 24 nucleotides encoding 8 amino acids. This exon is spliced into loop *I* of NMHC II-C and is present in a wide variety of tissues and cell lines. Insertion of this exon leads to an increase in the actin-activated MgATPase activity and *in vitro* motility of heavy meromyosin II-C compared to the noninserted isoform (Kim et al (2005) *J. Biol. Chem.* 280, pp 22769-75). RT-PCR analysis reveals that the mRNA encoding the inserted isoform is highly expressed in many human epithelial tumor cell lines such as liver, HepG2; prostate, PC-3; pancreas, PANC-1; breast, MCF-7, and lung, A-549 cells. Interestingly, when we quantitated the expression level of all three nonmuscle myosin isoforms (NMHC II-A, II-B and II-C) in tumor cell lines vs normal cell lines, the expression of inserted II-C was elevated (>8 fold) in the tumor cell lines compared to the normal cell lines. In contrast NMHC II-A and II-B were decreased (>3 and >4 fold respectively) in the tumor cell lines as determined by scanning immunoblots. Analysis of breast, kidney and lung tumors from humans confirmed the increase in NMHC II-C expression in all three tumors compared to their normal associated tissue. Using siRNA to reduce the inserted isoform by 90% in the A549 lung epithelial cancer cell line leads to 80% growth inhibition at 156 h. This inhibition of growth was almost completely rescued by exogenous expression of the inserted NMHC II-C, but only partially rescued by noninserted II-C. These studies suggest a putative role for the NMHC II-C isoform in certain epithelial tumor cell lines.

952

**Myosin Heavy Chain Kinase A from *Dictyostelium* Possesses a Novel Actin Binding Domain that Cross-Links Actin Filaments**

M. Russ, O. Ali, K. Amber, P. Steimle; Biology, University of North Carolina at Greensboro, Greensboro, NC

Myosin heavy chain kinase A (MHCK-A) catalyzes the disassembly of myosin II filaments in *Dictyostelium discoideum* via phosphorylation of the "tail" region of the myosin heavy chain. MHCK-A is recruited to actin-rich cortical sites and is preferentially enriched at sites of pseudopod formation. MHCK-A possesses an amino-terminal "coiled-coil" domain (designated C1-498) that mediates the oligomerization, cellular localization, and actin binding activities of the kinase. We have shown that C1-498 binding to F-actin leads to a 40-fold increase in MHCK-A activity, and thus may represent a potent mechanism for achieving highly-localized and robust disassembly of myosin II filaments in the cell. In the current study, we examined the actin-binding characteristics of the "coiled-coil" domain as a means of gaining insight into the mechanisms by which F-actin-mediated activation of MHCK-A, and thus myosin II filament disassembly, can be regulated in the cell. Co-sedimentation assays revealed that C1-498 protein binds cooperatively to F-actin with an apparent $K_D$ of ~0.5 μM and a stoichiometry of ~5:1 (actin:C1-498). By contrast, assays of "coiled-coil" domain truncations lacking either amino-terminal (C121-498) or carboxy-terminal (C1-452) regions exhibited ~50% reductions in actin binding, and a combined truncation lacking both ends (C121-452) exhibits complete loss of actin binding activity. Studies examining the nature of the interaction with F-actin revealed that C1-498 has the ability to cross-link adjacent actin filaments into bundles. These results are particularly notable since they represent the first demonstration of a serine/theronine protein kinase possessing an actin cross-linking domain. In a larger context, our results suggest that changes in the accessibility of actin-binding determinants in the "coiled-coil" domain leads to localized cross-linking of actin filaments which, in turn, may activate MHCK-A-mediated disassembly of myosin II filaments at specific cell sites.

**A Novel Role for Myosin II in Insulin-Stimulated Glucose Uptake in 3T3-L1 Adipocytes**

P. Steimle, K. Fulcher, Y. Patel; Biology, University of North Carolina at Greensboro, Greensboro, NC

Insulin-stimulated glucose uptake requires the activation of several signaling pathways to mediate the translocation and fusion of GLUT4 vesicles from an intracellular pool to the plasma membrane. The studies presented here show that inhibition of myosin II activity impairs GLUT4-mediated glucose uptake but not GLUT4 translocation to the plasma membrane. We also show that adipocytes express both myosin IIA and IIB isoforms, and that myosin IIA is recruited to the plasma membrane upon insulin stimulation. Taken together, the data presented here represent the first demonstration that GLUT4-mediated glucose uptake is a myosin II-dependent process in adipocytes. Based on our findings, we hypothesize that myosin II is activated upon insulin stimulation and recruited to the cell cortex to facilitate GLUT4 fusion with the plasma membrane. The identification of myosin II as a key component of GLUT4-mediated glucose uptake represents an important advance in our understanding of the mechanisms regulating glucose homeostasis.

954

**PDGF-mediated Activation of PKC controls Myosin Filaments Disassembly**

S. Komatsu, M. Ikebe; Physiology, University of Massachusetts Medical School, Worcester, MA

Phosphorylation of the regulatory light chain of myosin II (MLC) may play an important role in cell motile processes through the rearrangement of actomyosin filaments by facilitating motor activity and myosin filament stability. In vitro biochemical studies have shown that the function of myosin II is regulated by phosphorylation of MLC by MLC kinases and protein kinase C (PKC). Phosphorylation of MLC by MLC kinases (Thr-18 and Ser-19) promotes its motor activity and filament formation. On the other hand, phosphorylation of MLC by PKC (Ser-1 and Ser-2 and Thr-9) decreases the binding affinity of myosin II for actin and the affinity of MLC for MLCK thus down regulating the actin-activated ATPase activity of myosin II. However, the physiological significance of this inhibitory phosphorylation has not been established. To address this question, we developed a site-specific phospho antibody (pS1 Ab) that recognizes phosphorylated MLC at the inhibitory sites but not the activation sites. Immunochemical analysis using pS1 Ab revealed that phosphorylation of the inhibitory sites is correlated with platelet-derived growth factor (PDGF)-induced cell migration. Interestingly, reorganization of actomyosin filaments in response to PDGF stimulation is associated with the increase of phosphorylation at the inhibitory sites. The phosphorylation of myosin II at the inhibitory sites in response to PDGF was attenuated by the specific PKC inhibitors (GF109203X and Go6976), but not PI3 kinase (LY294002) and MEK (PD98059) inhibitors. To further clarify the physiological role of phosphorylation of MLC at the inhibitory sites, unphosphorylatable MLC mutant (SS/AA-MLC) was introduced into NIH3T3 cells. Expression of SS/AA-MLC but not wild type MLC inhibited the PDGF-induced stress fiber disassembly. These results suggest that phosphorylation of MLC at the inhibitory sites by PKC plays an important role in dynamic reorganization of myosin during cell migration.

### The Cyclin Dependent Kinase 5 Activator p39 Binds Myosin Essential Light Chain

B. K. Tripathi, D. R. Ledee, P. S. Zelenka; Laboratory of Molecular and Devempmental Biology, National Eye Institute / National Institutes of Health, Bethesda, MD

Cyclin dependent kinase 5 (Cdk5) and its activators, p35 or p39, are expressed in the lens and corneal epithelial cells where they play a role in regulating cell adhesion and migration. To better understand Cdk5 functions in these epithelial cells, we screened a yeast two hybrid library from embryonic rat lens using Cdk5, p35, and p39 as baits. This screen identified myosin essential light chain (MLC) as a potential binding partner of p39. This interaction was confirmed by isolating a protein complex containing GST-MLC and p39 (GST-pulldown). Pull-down experiments with p39 deletion constructs mapped the binding site for MLC to the p39 N-terminus. Co-transfection of fluorescence-tagged constructs of MLC and p39 showed colocalization of these proteins at cell boundaries and along cytoplasmic filaments, presumably cytoskeleton. Immunoprecipitation and immunoblotting of rat lens extracts confirmed that endogenous MLC and p39 form a protein complex. Immunoprecipitating lens extracts with antibody to non-muscle myosin heavy chain (MHC II-B) showed that myosin interacts with both p39 and muskelin, a protein that binds the p39 C-terminus. Although we did not detect endogenous Cdk5 in immunoprecipitates of MHC or MLC from lens, HA-Cdk5 and GFP-MLC co-immunoprecipitated from cotransfected cells, suggesting that Cdk5 may only transiently bind to the myosin-p39 complex *in vivo*. A potential substrate for Cdk5 in this complex is the alternatively spliced form of MHC II (MHC II-B1), a known substrate of Cdk5 in the brain. RT-PCR demonstrated that this isoform is also expressed in the lens. These data support the view that p39 may form a protein complex linking muskelin to myosin and thus to the cytoskeleton. Such a complex may position Cdk5 to phosphorylate MHC II-B1 or other cytoskeletal proteins involved in cell adhesion and movement.

### Identification and Characterization of an Unconventional Protein Kinase Localized to the Contractile Vacuole and Golgi Complex in *Dictyostelium Discoideum*

V. Betapudi, L. S. Licate, T. T. Egelhoff; Physiology and Biophysics, Case Western Reserve School of Medicine, Cleveland, OH

We have identified a novel unconventional protein kinase in *Dictyostelium discoideum* which carries the same conserved class of “alpha kinase” catalytic domain as previously reported in myosin heavy chain kinases (MHCKs) in this amoeba, but which has a completely novel domain organization. This protein of 625 amino acids contains an N-terminal von Willebrand Factor A (vWFA) motif (also known as beta-integrin motif), and is therefore named as VwkA. VwkA$^{-}$ and overexpressing (VwkA$^{++}$) cells showed reduced growth, multinucleation in suspension culture and failure to development and gene disruption lines (*vwkA*- cells) display a developmental delay. VwkA is cytosolic in distribution, but enriched on the membranes of the contractile vacuole and Golgi-like structures in the cell. Both VwkA++ and *vwkA*- cells display altered osmotic shock responses. Despite sequence similarity to MHCKs, the purified protein failed to phosphorylate myosin II in vitro, but overexpression and gene disruption showed a significant effect on myosin II assembly levels in vivo, suggesting a possibly indirect or upstream role for VwkA in modulating myosin II localization behavior.

## Tubulin (957-965)

957

### Cryo EM Studies of Effects on Microtubule Structure by Vinblastine-Tau

R. A. Santarella,[1] J. J. Correia,[2] S. Lobert,[2,3] A. Hoenger[1]; [1]EMBL, Heidelberg, Germany, [2]Biochemistry, Univ. Miss. Medical Center, Jackson, MS, [3]School of Nursing, Univ. Miss. Medical Center, Jackson, MS

Vinblastine is a destabilizer of microtubules that favors formation of spiral protofilament polymers. It is hypothesized that at $IC_{50}$ concentrations only microtubule ends are targets of drug binding leading to curved or open structures. To investigate this we have performed cryo-electron microscopy (cryo EM) and 3-D image analysis of vinblastine binding to microtubules +/- taxol in the presence and absence of tau (Htau40). Vinblastine alone extensively destabilizes MTs and promotes small curved oligomer formation. In the presence of taxol, vinblastine promotes formation of MTs with 15 or more protofilaments and reconstruction reveals altered subunit packing. MT ends exhibit prominent spaying of short protofilaments. In the presence of vinblastine and tau, long curved spirals and bundles of spirals grow prominently from taxol-MT ends. The background is also full of short curved oligomers, straight twisted protofilament rods, and large circular structures. The alterations at MT ends are observed even at low vinblastine concentrations when tau is present, as verified by metal shadowing experiments. This indicates that tau (and MT stabilizing proteins like tau) enhances growth of vinblastine spiral polymers at MT ends. We suggest that this is the mechanism by which vinblastine selectively disrupts MT growth and dynamics.

958

### A Novel Role for the βIII Isotype of Tubulin

P. Joe,[1] C. Walss-Bass,[2] O. Pressley,[3] I. Yeh,[3] R. Luduena[1]; [1]Biochemistry, University of Texas Health Science Center at San Antonio, San Antonio, TX, [2]Psychiatry, University of Texas Health Science Center at San Antonio, San Antonio, TX, [3]Pathology, University of Texas Health Science Center at San Antonio, San Antonio, TX

Vertebrate tubulin is an α/β heterodimer; both α and β consist of numerous isotypes that are highly conserved in evolution. The βIII isotype has an unusual distribution of cysteine residues. It lacks the highly conserved cys239, whose sulfhydryl group can be easily oxidized to inhibit microtubule assembly. On the other hand, βIII contains the unusual cys124, located close to the conserved cys127 and cys129. βIII is known to be abundant in neurons and to occur in colon epithelia. Using a βIII-specific monoclonal antibody, we have localized βIII to a variety of cells and tissues, including islets of Langerhans, ovarian follicles, Sertoli cells, megakaryocytes, and others, all of which contain high levels of free radicals (FR) and/or reactive oxygen species (ROS). We have found that treatment of neuroblastoma cells with glutamate, which induces NO production, causes a 67 % increase in βIII levels in 15 minutes. Treatment of MCF-7 breast cancer cells with diamide, a reagent that induces disulfide bridge formation in proteins, causes a five-fold increase in the level of βIII. Our results are consistent with the hypothesis that βIII may protect microtubules from the effects of FR and ROS. Since mitochondria are major producers of ROS, our results are also consistent with the finding of

Carré et al (*J. Biol. Chem.* **277**, 33644-33669 (2002)) that βIII is present in the mitochondrial membranes of neuroblastoma cells. (Supported by grants to RFL from the Welch Foundation (AQ-0726), and the US Army (W81XWH-04-1-0231, W81XWH-05-1-0238), to CWB from the Stanley Medical Research Institute, and to ITY from the San Antonio Cancer Institute (P30 CA54174)).

**Multipolar Mitotic Spindles May be Important for the Antimitotic Actions of Chemically Diverse Microtubule Stabilizers**

E. A. Clark, S. L. Mooberry; Department of Physiology and Medicine, Southwest Foundation for Biomedical Research, San Antonio, TX

Chemically diverse microtubule targeting agents interrupt mitosis and lead to initiation of apoptosis. A large body of evidence suggests that at the lowest effective concentrations, these drugs inhibit normal microtubule dynamics leading to mitotic arrest. Many investigators have noted that mitotic spindles formed in the presence of these drugs can be abnormal, specifically forming multipolar spindles. We evaluated the role of these multipolar spindles in the antiproliferative effects of paclitaxel, epothilone B, laulimalide, and taccalonolide A. Dose response curves were generated for each drug in three cell lines and the $IC_{25}$, $IC_{50}$, $IC_{75}$ and 5 x $IC_{50}$s determined. The lowest concentration causing total $G_2$/M arrest was identified using flow cytometry. It was significantly higher than 5 x $IC_{50}$. Cells were treated with the entire range of concentrations, and microtubules visualized. The percentage of cells in mitosis with bipolar or multipolar spindles was determined. The results showed a concentration dependent increase in the percentage of mitotic cells with multipolar spindles. These multipolar spindles occurred at low antiproliferative concentrations. At the $IC_{75}$, 50% or more of the mitotic cells had multipolar spindles and at 5 x $IC_{50}$, essentially 100% of the spindles were multipolar. To evaluate the timing of multipolar spindle formation, HeLa cells were synchronized by double thymidine blockade, released, and treated with paclitaxel at the lowest concentration that causes $G_2$/M arrest. Multipolar mitotic spindles were observed within 4 hr, at the transition between S and $G_2$/M, suggesting that multipolar spindle formation is an early causative event. Our data show a strong link between the formation of multipolar spindles, mitotic arrest, and the antiproliferative actions of diverse microtubule stabilizers. Studies are underway to test whether the multipolar spindles are formed by normal or aberrant nucleation pathways.

960

**Activities of Dolastatin 15 Peptide Analogs as Inhibitors of Tubulin Assembly and Vinblastine Binding**

M. C. Edler, R. Bai, E. Hamel; Toxicology and Pharmacology Branch, National Cancer Institute at Frederick, Frederick, MD

Dolastatin 15 and its analogs cemadotin and tasidotin are hydrolyzed intracellularly to a common active metabolite (*N*,*N*-dimethyl-Val-Val-*N*-methyl-Val-Pro-Pro), which is significantly more potent than its precursors as an inhibitor of tubulin assembly. Assuming the metabolite binds at the "peptide site" on tubulin, it represents the least modified of the peptide and depsipeptide natural products that inhibit tubulin assembly and mitosis. Since it has long been thought that drug binding sites on tubulin may represent sites for endogenous ligands, we examined $(Val)_3(Pro)_2$ for antitubulin activity and found it to be weakly active (about 20-fold less active than the trimethylated pentapeptide). This finding led us to undertake an initial structure-function study to determine the relative importance of the three methyl groups in the dolastatin 15 metabolite, to determine whether any of the residues in $(Val)_3(Pro)_2$ could be replaced and improve activity, and whether longer peptides than $(Val)_3(Pro)_2$ would have enhanced activity. We also searched the protein data base for the $(Val)_3(Pro)_2$ motif for clues for proteins that might interact with tubulin.

961

**Sanguinarine Inhibits Cell Proliferation by Inhibiting Microtubules Assembly through Tubulin Binding**

M. Lopus, D. Panda; School of Biosciences and Bioengineering, Indian Institute of Technology Bombay, Mumbai, India

We investigated the antiproliferative mechanism of action of sanguinarine, a benzophenanthridine alkaloid. Sanguinarine inhibited HeLa cell proliferation ($IC_{50}$ = 1.6 μM) by depolymerizing cellular microtubules. In the lower effective concentration range (1-3 μM), sanguinarine depolymerized microtubules of both mitotic and interphase cells. At relatively higher concentrations (> 2 μM) of sanguinarine, bundling of interphase microtubules and formation of granular aggregates were observed. The effects of sanguinarine on cellular microtubules were found to be irreversible. Sanguinarine inhibited assembly of microtubule proteins *in vitro*. It also inhibited assembly of purified tubulin. In addition, sanguinarine induced aggregation of tubulin. Sanguinarine was found to bind to tubulin and to induce changes in the secondary structure of tubulin. However, unlike several other tubulin targeting agents, sanguinarine did not arrest cells at mitosis. Further, we found that sanguinarine did not bind to the vinblastine site on tubulin. Sanguinarine exerted synergistic cytotoxic effects in combination with vinblastine. In addition, sanguinarine was found to exert synergistic cytotoxic effects on HeLa cells when used in combination with paclitaxel. The results together suggest that sanguinarine inhibits HeLa cell proliferation by perturbing microtubule assembly dynamics and that sanguinarine may have clinical potential in cancer chemotherapy. The work is supported by Department of Biotechnology, Government of India.

**Synthetic Peptides as Probes to Disrupt or Mimic the Interface between Tubulin and Gsα**

W. Saengsawang, B. T. Layden, T. Kobayashi, M. M. Rasenick; Physiology and Biophysics, University of Illinois at Chicago, Chicago, IL

Gsα has been shown to interact with tubulin with high affinity ($K_D$~130nM) and increase microtubule dynamics *in vitro* by stimulating tubulin GTPase. Conversely, tubulin appears to transfer its GTP to Gsα (transactivation) resulting in GPCR-independent activation of adenylyl cyclase. The potential domains on Gsα that interact with tubulin have been identified and the interface between these proteins has been modeled. The objective of this study is to develop peptides corresponding to Gsα sequences articulating between Gsα and tubulin. A peptide array membrane corresponding to tubulin interaction domains on Gsα as well as corresponding domains on Gtα (which does not bind to tubulin) were created to investigate the specific binding site of Gsα to tubulin. Peptides from these regions were synthesized. Surface Plasmon Resonance was used to determine the binding affinity of these peptides to tubulin. Photoaffinity labeling with the GTP photoaffinity analog P3-1,4-azidoanilido-P1-5'-GTP (AAGTP) was used to study the effect of these peptides on nucleotide bound tubulin and on the transactivation of Gsα. We found 14 peptides from Gsα that show binding to tubulin compared to the corresponding Gtα peptide. We synthesized peptides from the switch II and switchIII regions of Gsα. We found that these peptides bind to tubulin with $K_D$~5μM. Interestingly, each of these peptides cause tubulin to lose its nucleotide in concentration dependent manner and block transactivation of Gsα. These results suggest that Gsα derived peptides bind to tubulin and alter the affinity of nucleotide binding to tubulin. This study will provide novel insight into domains on Gsα that interact with and/or alter the nucleotide

binding site on tubulin. It will also aid in an understanding the interface between G protein signaling and the cytoskeleton. Support NIMH MH39595

### Tissue Distribution of the βV Isotype of Tubulin

I. Yeh,[1] A. Banerjee,[2] O. Pressley,[1] J. De Luna,[2] R. F. Luduena[2]; [1]Pathology, University of Texas Health Science Center at San Antonio, San Antonio, TX, [2]Biochemistry, University of Texas Health Science Center at San Antonio, San Antonio, TX

Of the various isotypes of β-tubulin, perhaps least is known about βV. In order to examine this further, we have developed a monoclonal antibody specific for βV. We have surveyed various tissues with this antibody and found that βV is present in a relatively small number of cell types. These include the islets of Langerhans, intestinal glands, macrophages, megakaryocytes, and glia. In cultured cells, βV is strongly present in C6 glioma and PC3 prostate cancer cells, but only weakly in MCF-7 breast cancer and HeLa cells. However, in formalin fixed, paraffin embedded sections, we have found strong βV staining in a low-grade breast ductal carcinoma *in situ* (DCIS), but not in a high grade DCIS. Interestingly, βIII was present in both of these. The tissue distribution of βV is strikingly similar to that of βIII. These tissues are rich in free (FR) radicals and reactive oxygen species (ROS). Notably, both βV and βIII contain a cysteine cluster at positions 124, 127 and 129 and lack the highly oxidizable cys239 found in most of the other β isotypes. (Supported by grants to RFL from the Welch Foundation (AQ-0726), and the US Army (W81XWH-04-1-0231; W81XWH-05-1-0238) and to ITY from the San Antonio Cancer Institute (P30 CA54174)).

### Purification and Characterization of Tubulin from *Agaricus bisporus*

B. Arthur, K. M. Middleton, A. S. Davis; Cytoskeleton Inc, Denver, CO

The incidence of invasive fungal infections in humans has risen dramatically over the past twenty years. In addition to human pathologies, numerous fungal pests threaten agricultural crops. Anti-fungal drug development for medical and agricultural use has been limited by the inability of these compounds to target pathogens specifically, subjecting the host to few negative effects. One drug target is tubulin, a cytoskeletal protein that is essential for both cell division and survival. Targeting of this protein for drug development is complicated by the fact that tubulin orthologs are expressed in all eukaryotes. It follows that for an anti-fungal tubulin drug to be efficacious, it must show high specificity for the pathogenic tubulin. A principal obstacle in determining the species specificity of anti-tubulin compounds is the lack of an *in vitro* system wherein the drug's effect on tubulin from different species can be compared. Here we describe the purification and characterization of tubulin from the fungus *Agaricus bisporus.* Tubulin was purified and polymerization conditions were established resulting in microtubules that ranged from 8 to 15 µm. The critical concentration was 0.3 mg/ml, lower than that of bovine tubulin. These conditions yielded 0.9 mg/ml of polymer/$OD_{340}$/cm, compared to 5.0 mg/ml of polymer/$OD_{340}$/cm for bovine tubulin. Compounds that act as polymerization inhibitors, such as rhizoxin (10 µM), or stabilizers, such as paclitaxel (10 µM), were found to decrease and enhance polymerization, respectively. This system can be used to determine the activity of a candidate compound on fungal tubulin polymerization. In future studies, drug activity determinations for *A. bisporus* tubulin will be conducted in parallel with mammalian tubulin, thereby allowing comparisons to be made regarding the compound's specificity for tubulin from different species.

965

### Characterization of NUD-1 Interactors in *C elegans*

J. G. Phillips, R. Thomas, M. Till, K. Peters, G. A. Caldwell, K. A. Caldwell; Biological Sciences, The University of Alabama, Tuscaloosa, AL

NUD-1 is the *C. elegans* ortholog of a conserved family of proteins originally identified in a screen for proteins affecting nuclear positioning within the hyphae of the filamentous fungus *Aspergillus nidulans*. We have previously shown functional conservation between *A. nidulans* NUDC and NUD-1, as well as evidence that the worm *nud-1* gene is expressed in a variety of *C. elegans* cell types, including neurons, mutlinucleated tissues, and mitotically dividing cells. The *C. elegans* one-celled embryo represents an excellent system by which cellular components involved in the cytoskeleton can be elucidated. In this regard, we report evidence that gamma-tubulin is not localized to centrosomes in *nud-1* (RNAi) *C. elegans* embryos. These data are corroborated by mammalian studies wherein NudC has been shown to interact with dynein and to colocalize with p150dynactin and with gamma-tubulin. It is thought that NUD-1 probably interacts with a variety of proteins; the structure of NUD-1, which contains putative protein interaction domains, is suggestive of this functionality. Current work is directed toward investigating the relationship between gamma-tubulin, NUD-1, and other potential interacting proteins using a combination of biochemical analysis and immunocytochemistry.

### BOP2 Encodes a Novel WD-Repeat Protein that Regulates Inner Arm Dynein Activity

C. A. Perrone,[1] D. Tritschler,[1] R. Bower,[1] E. T. O'Toole,[2] M. J. Wargo,[3] E. F. Smith,[3] M. E. Porter[1]; [1]Genetics, Cell Biology & Development, University of Minnesota, Minneapolis, MN, [2]Molecular, Cellular, & Developmental Biology, University of Colorado, Boulder, CO, [3]Biological Sciences, Dartmouth College, Hanover, NH

To identify novel components involved in the regulation of flagellar motility, we screened a collection of motility mutants generated by insertional mutagenesis. Analysis by thin section electron microscopy and image averaging identified three slow swimming strains that share similar defects in the assembly of a distally located inner arm structure. Recovery of genomic DNA flanking the site of plasmid insertion and RFLP mapping demonstrated that all three strains are mutant alleles at the *BOP2* locus. Rescue by transformation revealed that *BOP2* expresses an ~5kb transcript encoding a highly conserved, 145 kD, WD-repeat containing polypeptide. Western blot analysis of isolated axonemes and dynein extracts showed that BOP2 co-fractionates with a subset of inner arm subunits. Sequencing of the original *bop2-1* allele (isolated as a suppressor of *pf10*, Dutcher et al., 1988) identified a single base pair change in a splice acceptor site. The mutation results in a complex pattern of alternative splicing at cryptic splice sites downstream, and the new transcripts contain premature stop codons. These results suggest that *bop2-1* is effectively a null allele, consistent with the absence of a BOP2 signal on Western blots. Analysis of microtubule sliding patterns and velocities further demonstrate that the

regulation of dynein activity on specific doublets is defective in *pf10* axonemes. However, microtubule sliding shifts to a more wild-type-like pattern in *bop2 pf10* double mutants. Collectively, these results suggest BOP2 is an inner arm associated polypeptide involved in regulating microtubule sliding on specific subsets of doublet microtubules (Supported by the NIH).

967

**Localization of a Regulatory Intermediate Chain (IC) Complex at the Base of the I1 Dynein**

R. Bower,[1] C. A. Perrone,[1] J. Mueller,[1] E. T. O'Toole,[2] M. Wirschell,[3] L. Fox,[3] W. S. Sale,[3] M. E. Porter[1]; [1]Genetics, Cell Biology & Development, University of Minnesota, Minneapolis, MN, [2]Molecular, Cellular, & Developmental Biology, University of Colorado, Boulder, CO, [3]Cell Biology, Emory University School of Medicine, Atlanta, GA

Our goal is to understand how the *Chlamydomonas BOP5* gene product, the IC138 phosphoprotein, contributes to the assembly and regulation of the I1 inner arm dynein (Hendrickson et al., 2004). Here we focus on an unusual *bop5* motility mutant, 6F5, isolated by insertional mutagenesis. Southern blots and PCR showed that >90% of the *IC138* gene is deleted in 6F5. In backcrosses to a *nit1* strain with wild-type motility, the motility defect co-segregates with the absence of IC138. To assess how the loss of IC138 affects the other I1 subunits, we analyzed 6F5 axonemes on Western blots. Most null mutations in other dynein ICs block complex assembly. Contrary to expectation, most I1 subunits are present in 6F5 axonemes, but both IC138 and IC97 are missing (see also Wirschell et al., these proceedings**)**. Fractionation of 6F5 dynein extracts by sucrose density gradient centrifugation revealed that the remaining I1 subunits are dissociated into two distinct peaks. IC138 and IC97 are therefore components of the I1 dynein, but not required for its assembly in the axoneme. Analysis of 6F5 axonemes by image averaging of longitudinal sections revealed a defect at the base of the I1 dynein, in close proximity to radial spoke 1 and outer dynein arms. Microtubule sliding velocities are also reduced in 6F5 axonemes. Transformation with a wild-type copy of *IC138* restores assembly of both IC138 and IC97 and increases sliding velocities to wild-type levels. Taken together, these observations are consistent with the hypothesis that IC138 (and possibly IC97) play a central role in mediating signals between the radial spokes and dynein arms (supported by NIH).

968

**25 Dynein Heavy Chains in *Tetrahymena thermophila*: Evidence that the Dynein Family Evolved in Two Stages**

D. E. Wilkes, H. Watson, D. J. Asai; Department of Biology, Harvey Mudd College, Claremont, CA

We have identified 25 dynein heavy chain (DYH) genes that are expressed in *Tetrahymena thermophila.* These include the 14 DYH genes previously described (Asai and Wilkes, 2004, J. Eukaryot. Microbiol. 51: 23-29), and 11 new DYH genes inferred to encode single-headed axonemal dyneins. The expression of the 11 newly identified DYH genes was upregulated in cells that had been deciliated. Phylogenetic analyses of the motor domains of dyneins from *Tetrahymena* and other model organisms revealed two patterns of groupings. The DYH1-7 sequences group with orthologous sequences from other organisms. In contrast, DYH8-25 mostly grouped in organism-dependent clusters. For example, there is a large clade of protistan (*Chlamydomonas* and *Tetrahymena*) dyneins, there are clades of only *Tetrahymena* dyneins, and there are clades of only animal dyneins. These results suggest that the present family of dynein heavy chains evolved in two stages. DYH1-7 plus the ancestor of the DYH8-25 genes emerged early, prior to the divergence of the last common ancestor of extant eukaryotes (see D.R. Mitchell, 2004, Biol Cell 96: 691-696). In *Tetrahymena*, these functionally specialized "foundation" dyneins comprise two non-axonemal dyneins (*Tetrahymena* DYH1 and DYH2), three-headed ciliary outer arm dynein (DYH3-5), two-headed inner arm dynein (DYH6,7), and a single-headed inner arm dynein. The second stage involved the duplication and subsequent divergence of the single-headed dynein, resulting in DYH8-25; the second stage occurred after the radiation of organisms. Perhaps the additional dyneins enabled the organism to further specialize axonemal motility and/or rapidly form new cilia. Supported by grants from the National Science Foundation and the Howard Hughes Medical Institute.

969

**Identification of a Third Member of the LC8 Family of Dynein Light Chains in *Chlamydomonas* Flagella**

P. Rompolas,[1] R. S. Patel-King,[1] O. Gorbatyuk,[1] K. Wakabayashi,[1] G. J. Pazour,[2] S. M. King[1]; [1]Department of Molecular, Microbial and Structural Biology, University of Connecticut Health Center, Farmington, CT, [2]Program in Molecular Medicine, University of Massachusetts Medical School, Worcester, MA

Members of the LC8 family of dynein light chains (LCs) are highly conserved from algae to humans, and are thought to play an essential role in assembly of the dynein motor complex. LC8 and LC6, the founding members of this family, were initially identified in *Chlamydomonas* outer dynein arms. Analysis of the *Chlamydomonas* genome identified a gene that encodes a third member of this family (here termed LC10) which shares 48 and 28% identity with *Chlamydomonas* LC8 and LC6, respectively. LC10 contains 103 amino acids with a molecular mass of 12,086 Da and a pI of 5.28. Northern blotting identified a single 1.2 kb mRNA that is highly up-regulated upon deflagellation. Immunoblot analysis demonstrated that an antibody raised against a MBP/LC10 fusion protein reacted strongly with LC10, but specifically did not detect either LC6 or LC8. Furthermore, we found that LC10 is a flagellar component that is not solubilized by detergent treatment, but is readily extracted from axonemes by 0.6 M NaCl. In addition, flagella from the mutants *oda1* (missing outer arms and the docking complex) and *oda2* (missing only outer arms) were found to completely lack LC10. This strongly suggests that LC10 is an integral component of the outer dynein arm. The LC10 gene is located close to the *ODA12* locus that encodes the essential outer arm protein LC2; this gene is missing in the *oda12-1* insertional allele, but not in *oda12-2*. Transformation of *oda12-1* with the LC2 gene alone restores outer arm assembly (Pazour et al [1999] Mol Biol Cell 10, 3507-3520). We are currently using this LC10-deficient strain to assess whether the lack of LC10 has consequences for outer arm dynein function.

970

**Association of the Cytoplasmic Dynein Intermediate Chain Isoforms**

K. W. Lo, K. Pfister; Cell Biology, University of Virginia, Charlottesville, VA

The cargo binding domain of Cytoplasmic Dynein 1, the multi-subunit protein complex responsible for many different microtubule-based intracellular movements, consists of dimers of five subunits; intermediate chains, light intermediate chains, and three families of light chains. Alternative splicing of the two intermediate chain genes results in six protein isoforms. It has been hypothesized that different intermediate chain isoforms may regulate specific dynein functions. However, only minimal data on the potential combinations of the intermediate chain isoforms in

the dynein complex has been available. To determine if different intermediate chains are able to associate, pairs of epitope-taged intermediate chains were expressed in cultured cells. Co-immunoprecipation analyses of the transfected proteins demonstrate that the six intermediate chains form all combinations of homodimers and heterodimers. Therefore the formation of dynein complexes with different combinations of isoforms is not limited by interactions between the various intermediate chains. We next sought to map the domain necessary for the dimerization of the intermediate chains. A series of epitope-tagged truncation mutants of intermediate chain 2C, were expressed in cultured cells. Co-immunoprecipitation analyses showed that the region necessary for dimerization is restricted to amino acids 150 - 250 of the intermediate chain. This amino acid sequence does not include either of the two intermediate chain regions with motifs that are often involved in protein-protein interactions, the N-terminal coiled-coil and the C-terminal WD repeat domains. This sequence is also downstream from the binding domains for the LC8 and Tctex1 light chains. Therefore binding of those two light chains is not required for intermediate chain dimerization. Interestingly, this amino acid sequence does include the Roadblock light chain binding domain, and we are investigating the importance of the Roadblock light chains for the dimerization of the intermediate chains in the dynein complex.

**Complexity of Cytoplasmic Dynein Light Chain Expression in COS-7 Cells**

S. L. Bird, P. S. Vaughan, K. T. Vaughan; Biological Sciences, University of Notre Dame, Notre Dame, IN

Cytoplasmic dynein is an abundant microtubule motor protein in COS-7 cells and is responsible for the transport of multiple cargos during interphase and mitosis. Similar to other cytoplasmic dynein subunits, multiple isoforms of the Tctex-1, LC8 and LC7 light chains (LCs) have been identified and characterized. We are interested in how many populations of dynein are needed to accomplish all dynein functions in COS-7 cells and analysis of the LCs is complicated by the possibility of LC isoform expression. Because COS-7 cells have been shown to express a limited subset of IC isoforms (Vaughan et al., 2001), we explored the complexity of LC expression with the goal of performing immunofluorescence microscopy and siRNA analysis on each LC class. We utilized RT-PCR based on known sequence information to amplify light chain cDNA sequences from COS-7 cell mRNA. We then employed cloning, sequencing, and sequence comparisons to identify which LC isoforms were expressed. Because variable expression of each isoform was possible, we analyzed 9 independent isolates for LC8, 10 for Tctex-1 and 9 for LC7. Similar to our findings for other cytoplasmic dynein subunits, COS-7 cells express a single isoform of the Tctex-1, LC8 and LC7 LCs. This suggests that a single population of cytoplasmic dynein is capable of executing all interphase and mitotic dynein functions. For siRNA analysis, we have identified promising siRNA targets using sequence scanning programs and designed and created siRNA-expressing plasmid constructs. This analysis resulted in the creation of four different target siRNA sequences for each LC, which allows comprehensive analysis of LC depletion. In conclusion, COS-7 cells express a limited number of LC isoforms which simplifies our analysis of LC function and targets for siRNA analysis. (Supported by NSF-REU Program and NIH GM60560).

972

**Complexity of P150$^{Glued}$ Phosphorylation**

L. Casaletti, P. S. Vaughan, K. T. Vaughan; Biological Sciences, University of Notre Dame, Notre Dame, IN

A growing number of microtubule (MT) binding proteins display a behavior known as "tip-tracking" when they are expressed as GFP fusion proteins (Vaughan, 2004). Recent work on the p150$^{Glued}$ subunit of dynactin suggests that tip-tracking reflects a dynamic association with MTs which is released by phosphorylation. Although several lines of evidence suggest that members of the PKA family are involved, other kinases have also been implicated. The mammalian target of rapamycin (mTOR) was identified recently as another potential kinase that regulates MT tip-tracking proteins (Choi et al., 2002). We have assessed the role of mTOR phosphorylation on p150$^{Glued}$, EB1 and CLIP-170 by: 1) 2-D gel analysis of control cells and cell treated with rapamycin, 2) immunofluorescence and live-cell imaging of cells expressing GFP-p150$^{Glued}$ or EB1-GFP after treatment with rapamycin, and 3) imaging of cells over-expressing wild-type mTOR, mTOR kinase-dead mutants and rapamycin-resistent mTOR mutants. These findings reveal that mTOR has a differential effect on p150$^{Glued}$ and EB1. Based on the results of rapamycin treatment, it appears that mTOR activity promotes the binding of p150$^{Glued}$ to microtubules (in contrast to PKA) but directs the release of EB1 from MTs. This effect on p150$^{Glued}$ appears to be indirect, because inhibition of mTOR with rapamycin results in an increase in p150$^{Glued}$ phosphorylation complexity by 2-D gel analysis. To dissect these findings, we performed *in-vitro* microtubule-binding assays using recombinant p150$^{Glued}$ (1-330) in the presence of control or rapamycin-treated COS-7 cell extracts. Rapamycin-treated extracts decreased the affinity of p150$^{Glued}$ for MTs (via p150$^{Glued}$ phosphorylation) and this effect was not influenced by site-directed mutations at other phosphorylation sites. This work suggests that multiple pathways regulate p150$^{Glued}$. (Supported by NIH and DOD grants to KTV).

973

**Cytoplasmic Dynein Phosphorylation Changes Subunit Composition and Regulates Dynein Localization During Mitosis**

J. Whyte,[1] W. S. Lane,[2] K. Pfister,[3] S. M. King,[4] P. S. Vaughan,[1] K. T. Vaughan[1]; [1]Biological Sciences, University of Notre Dame, Notre Dame, IN, [2]Biological Sciences, Harvard University, Cambridge, MA, [3]Cell Biology, University of Virginia Health Sciences Center, Charlottesville, VA, [4]Biochemistry, University of Connecticut Health Center, Farmington, CT

Previous work identified a phosphorylation site in the dynein intermediate chains (ICs) which regulates binding to the putative receptor complex dynactin (Vaughan et al., 2001). To identify dynein kinases, we examined mitotic cytoplasmic dynein and determined that the ICs are phosphorylated by gel-shift and 2D gel analysis. ICs were subjected to MS/MS analysis revealing two novel phosphorylation sites. T89 falls within the binding domain for dynactin, and site directed mutants designed to mimic a phosphorylated state reduce dynactin binding significantly. T89 fits the consensus for p38MAPK and phosphorylation by p38MAPK is specific for this site *in vitro*. Inhibition of p38MAPK results in premature redistribution of dynein from kinetochores to spindle poles and results in lagging chromosomes during anaphase. Y130 falls within a domain implicated in LC8 (a dynein light chain) binding and fits the consensus for phosphorylation by *c-abl* kinase. *C-abl* phosphorylates wild-type but not Y130F mutant ICs *in vitro*. This phosphorylation was blocked by treatment with Gleevec (a *c-abl* inhibitor) and Gleevec treatment of live cells also blocked phosphorylation at Y130, suggesting that *c-abl* is a mitotic dynein kinase. Binding assays to test the impact of Y130 phosphorylation demonstrated that phosphorylated ICs bind less LC8 than dephosphorylated ICs. Immunostaining with antibodies generated against the phosphorylated ICs reveal that this phospho-isoform is not present in interphase cells. Instead these antibodies label dynein at the cell cortex in

mitosis and this labeling becomes prominent during late stages of mitosis. Interestingly, phospho-Y130 antibodies also brightly label the congressing furrows of cells undergoing cytokinesis. These results suggest that phosphorylation of ICs modulates subunit composition during mitosis and plays a role targeting dynein to multiple functional sites during mitosis. Supported by NIH GM60560.

974

**Alternative Splicing as a Mechanism to Modulate the Specificity of Cytoplasmic Dynein Phosphorylation**

S. Tauhata,[1] J. Burke,[1] E. Joseph,[1] W. S. Lane,[2] S. M. King,[3] K. Pfister,[4] P. S. Vaughan,[1] K. T. Vaughan[1]; [1]Biological Sciences, University of Notre Dame, Notre Dame, IN, [2]Biological Sciences, Harvard University, Cambridge, MA, [3]Biochemistry, University of Connecticut Health Center, Farmington, CT, [4]Cell Biology, University of Virginia Health Sciences Center, Charlottesville, VA

Although common in higher eukaryotes, the function of alternative splicing is not understood completely. Analysis of the cytoplasmic dynein intermediate chains (ICs) in neurons reveals expression of six isoforms derived from alternative splicing of two gene products. Because this splicing is restricted to the binding domain for the p150$^{Glued}$ subunit of dynactin, we developed binding assays using each IC isoform and determined that these isoforms share similar affinity and specificity for p150$^{Glued}$. To explore differences between isoforms, we performed MS/MS analysis on each polypeptide to map phosphorylated residues. Each isoform displayed phosphorylation in the p150$^{Glued}$-binding domain of the ICs, however the specific sites of phosphorylation were unique to each isoform. In addition, the sites fit consensus sequences for different kinases suggesting that each dynein subpopulation is regulated by an independent signaling pathway. Because the binding sites for two dynein light chains (LCs) are in close proximity to the phosphorylation sites, we compared the binding affinities of ICs alone and ICs with either a full or partial LC complement. The presence of LCs in the IC preparations did not improve the affinity of ICs for p150$^{Glued}$ nor did it change the binding specificity. In mixtures of IC isoforms however, the presence of LCs drove formation of IC homodimers rather than heterodimers suggesting a role in isoform sorting and selection during complex assembly. These studies suggest that alternative splicing of the dynein ICs presents different recognition sequences for dynein kinases and directs phosphorylation by isoform-specific kinases. The presence of dynein LCs drives the formation of isoform homodimers which ensures that each dynein molecule is regulated by a single kinase. Given the similarities to other neuronal microtubule motors, this could be a universal mechanism to enhance regulatory diversity in neurons.

**A Novel Microtubule-Binding Domain within Dynactin Increases the Processivity of Cytoplasmic Dynein**

S. J. King, T. L. Culver, S. A. Lex; School of Biological Sciences, University of Missouri-Kansas City, Kansas City, MO

The multiple roles that the cytoplasmic dynein activator dynactin plays inside cells require dynactin molecules to bind different regions of cellular microtubules and with different physicochemical properties to those microtubules. Here, we discovered that dynactin contains a novel microtubule-binding domain in addition to a previously described CAP-Gly domain. The newly identified domain is highly basic and is present only in the dynactin members of the CAP-Gly family of proteins. Using single-particle assays, we found that the dynactin CAP-Gly domain remains firmly attached to a single point on a microtubule. Interestingly, the dynactin basic domain progressively moves along the microtubule in the absence of any molecular motor, a process we have termed skating. To determine the physiological relevance of microtubule skating we performed motility assays with beads coated with both the motor cytoplasmic dynein and p150 polypeptides that contained one of the two microtubule-binding domains. We found that the p150 basic domain increased the processivity (run length) of cytoplasmic dynein motility events. In contrast, the p150 CAP-Gly domain did not enhance cytoplasmic dynein motor processivity. Our data suggest that the ability of individual dynactin molecules to skate along microtubules is utilized by cytoplasmic dynein as a tether to maintain contact with the microtubule cytoskeleton, thereby increasing dynein processivity. The dynactin skating behavior is the first description of a motor-independent mobile binding interaction between a protein and a biological polymer outside of DNA/sliding clamp interactions and may thus herald a new mechanism for dynamic protein/protein interactions.

976

**Impact of Transfected Cytoplasmic Dynein Subunits on Dynein-based Transport**

W. L. Towns, P. S. Vaughan, K. T. Vaughan; Biological Sciences, University of Notre Dame, Notre Dame, IN

Cytoplasmic dynein is a microtubule motor protein responsible for the transport of multiple cargos. In previous work, we mapped a phosphorylation site (Ser-84) in the dynein intermediate chains (ICs) and determined that this phosphorylation modulated the binding of the ICs to dynactin. To test if IC phosphorylation affected additional aspects of dynein function, we prepared GFP-tagged versions of wild-type and truncated ICs, as well as mutants mimicking the dephospho- and phospho-states. Using cell lysates from IC-transfected cells, we utilized immunoprecipitation analysis and sucrose gradient analysis to show that IC phosphorylation does not appear to affect other dynein activities such as dynein complex assembly and dynein light chain (LC) recruitment. We have compared our results using alternative methods of cell lysis to test if IC transfection has an impact on dynein complex stability. Sucrose density gradient sedimentation analysis of "osmotically swollen" lysates produces IC peaks that are markedly sharper and more shifted towards 20S fractions compared to detergent lysis. Immunoprecipitates from these 20S fractions with anti-GFP reveals that transfected IC-GFP incorporates into dynein and co-assemble with native ICs less effectively than 20S fractions from detergent lysates regardless of phosphorylation state, or the presence of the WD40 repeat domain. We also probed the osmotic lysate 20S immunoprecipitates for the Tctex-1, LC8, and LC7 LCs. Wild-type as well as phospho-mimicking ICs displayed little if any binding of each LC class. These results suggest that transfected IC constructs mediate their dominant negative effects primarily through saturation of dynein receptors rather than through disruption on native dynein complexes. (Supported by the AHA and NIH).

977

**Differential Light Chain Assembly Influences Outer Arm Dynein Motor Function**

L. M. DiBella,[1] O. Gorbatyuk,[1] M. Sakato,[1] K. Wakabayashi,[1] R. S. Patel-King,[1] G. J. Pazour,[2] G. B. Witman,[3] S. M. King[1]; [1]Department of Molecular, Microbial and Structural Biology, University of Connecticut Health Center, Farmington, CT, [2]Program in Molecular Medicine, University of Massachusetts Medical School, Worcester, MA, [3]Department of Cell Biology, University of Massachusetts Medical School, Worcester, MA

The intermediate chain/light chain (IC/LC) complex of *Chlamydomonas* outer arm dynein contains at least six distinct LC species. The *oda6*

mutant is unable to assemble outer arms due to the lack of IC2. An intragenic pseudorevertant at the *oda6* locus (*oda6-r88*) contains 23 residues altered from wildtype and can assemble outer arms (Mitchell & Kang [1993] J Cell Sci 105, 1069-1078). However, this strain exhibits significantly reduced flagellar beat frequency (~30 Hz), whereas a second pseudorevertant (*oda6-r75*), containing 10 altered residues in a region of IC2 adjacent to the *oda6-r88* deficiency, appears essentially wildtype (~55 Hz). Immunoblot analysis revealed that LC2 (Tctex2), LC6 (related to the highly conserved LC8 protein) and LC9 (Tctex1) are specifically missing in *oda6-r88*, but not in *oda6-r75*. The *oda6-r88* motility phenotype is not due to the lack of LC6 alone, as the LC6 null mutant (*oda13*) exhibits only a minor swimming abnormality. Intriguingly, we found that the LC2 null mutant (*oda12-1*) assembles some outer arm proteins; however, they are apparently non-functional as beat frequency of this strain is only ~20 Hz. This suggests that there is a functional difference between dyneins assembled in the absence of LC2 (from *oda12-1*) compared to dyneins that merely do not incorporate this protein (from *oda6-r88*). Furthermore, o*da6-r88* is not an extragenic suppressor of *oda12-1*, as the double mutant has a beat frequency similar to *oda12-1*. We did find that *oda12-1* dynein contains LC6 and minor amounts of LC9, raising the possibility that assembly of LC6 in the absence of LC2 may be detrimental. These data suggest that LC2, LC6 and LC9 have different roles in outer arm assembly and that one or more of these proteins is required for wildtype motor function in the *Chlamydomonas* flagellum.

978

**Stepwise Movements of the Motor Proteins in a Breast Cancer Cell**

T. M. Watanabe; Center for Interdisciplinary Research, Tohoku University, Sendai, Japan

Motor proteins, myosin, kinesin and dynein, involve in membrane transport in cells. *In vitro* motility assay and single-molecule measurement technology have revealed the motile mechanism of the motor proteins. However, in the living cell, there are many additional factors to consider apart from the condition *in vitro*; for example, ionic strength, adaptor proteins, cytoskeleton, viscoelasticity. The direct observation of the movements of the motor protein in cell is necessary to understand the molecular mechanism of the transportation. Here, we tried to observe the elements of the movements of the motor proteins in living cell using new techniques. To observe the movement of motor proteins in a cell for long time and with high temporal resolution, stable and intense Quantum dots (QD) labeled to HER2 (Human EGF Receptor 2) via antiboby (antiHER2-QD) was encytosed into a breast cancer cell in which HER2 was overexpressed. We observed the transportation of antiHER2-QD in three dimensions (3D) using new confocal microscopic system, which could obtain one set of 9 conforcal images at serial focal positions within 330ms. As a result of 3D observations, after endocytosis, antiHER2-QD moved along the membrane, and then was transported towards the nucleus. The movement along the membrane was related to the actin-dependent motor, most likely myosin VI, and the transportation toward the nucleus was related to dynein. Next, we measured each movement at nm, ms revel using modified-FIONA (Fluorescence Imaging with One Nanometer Accuracy) method. The movement along the membrane consisted of 29 and 16 nm steps, suggesting that myosin VI in cell walks on one side of an actin filament like a ropewalker. The movement toward the nucleus consisted of successive 8 nm steps. Therefore we concluded the unitary stepsize of dynein in cell is 8 nm.

979

**Kinetic Analysis of Tail Motions of Cytoplasmic Dynein Motor Domain**

T. Mogami, T. Kon, R. Ohkura, K. Sutoh; Life Sciences, University of Tokyo, Tokyo, Japan

Cytoplasmic dynein is a microtubule-based minus-end directed motor protein and is a large multi-component protein composed of two identical heavy chains (DHC), several intermediate, light intermediate, and light chains. The motor domain is composed of the C-terminal two-thirds of the DHC (380kDa) which contains several functional domains, i.e. AAA ring, stalk and tail domains. The AAA ring contains six AAA ATPase modules arranged in a ring-like shape. The N-terminal 160kDa region extending from the AAA ring forms the tail domain, which is responsible for dimerization and cargo binding. The primary ATPase site responsible for force generation is thought to reside in the first AAA module. The question of how structural changes of DHC induced by ATP hydrolysis are coupled with force generation remains to be answered. To detect structural changes of the tail against the AAA ring of DHC, BFP-GFP-based FRET measurements have been carried out on the recombinant 380kDa motor domain. The swing-like motions of the tail induced by ATP hydrolysis were detected as FRET efficiency changes. Two FRET states, State I and State II, were detected during ATP hydrolysis. The conformational transition from State I to State II was triggered by binding of ATP, and that from State II to State I occurred possibly at the ADP-release step. The purpose of this work was to perform kinetic analysis of transitions between the two conformational states. Rates of the transitions were determined by stopped flow measurements of FRET efficiency changes. The measurements also showed that the rate of transition from State II to State I increased several-fold on addition of microtubules, whereas the rate of the other transition was not. These results were consistent with the model that the tail motion is the power-stroke of dynein motor.

**Single Dynein-Dynactin Complexes Exhibit Bidirectional Motion *in vitro***

J. L. Ross,[1,2] K. Wallace,[2] H. Shuman,[1,2] Y. E. Goldman,[1,2] E. Holzbaur[2,1]; [1]Pennsylvania Muscle Institute, University of Pennsylvania, Philadelphia, PA, [2]Physiology Dept, University of Pennsylvania, Philadelphia, PA

Cytoplasmic dynein is a microtubule associated molecular motor essential for diverse functions in eukaryotic cells, such as retrograde axonal transport and mitosis. Dynein and dynactin complex in vivo to couple cargo to the dynein motor protein and allow transport. In order to further understand the properties of the dynein-dynactin complex, we have directly observed the motility of a GFP-labeled dynactin complexed to dynein in vitro using total internal reflection fluorescence microscopy. While motility is predominantly minus-end directed, our data shows that individual dynactin-dynein complexes display processive events (~1 um) in both minus-end and plus-end directions along microtubules under the zero-load conditions in our assay. The ability to switch direction and move bidirectionality is a unique property that may have biological relevance for transport in vivo. In addition, the velocity exhibits bi-phasic kinetics as a function of ATP that are a direct consequence of the AAA structure of the dynein head, which is distinct from other motor protein families. **Testing the Requirement of Dynein and Microtubule Depolymerization during Asymmetric Spindle Positioning of *C elegans* Embryos**

T. Nguyen-Ngoc, P. Gönczy; ISREC and EPFL, Lausanne, Switzerland

Spindle positioning is essential for spatial control of cell division, as it dictates the size and position of daughter cells. During the first mitotic division of the *Caenorhabditis elegans* embryo, the spindle elongates asymmetrically toward the cell posterior, giving rise to an unequal division along the anterior-posterior axis. Asymmetric spindle elongation is achieved by an imbalance of forces acting on the two spindle poles, with a larger net force pulling on the posterior pole (Grill et al., 2001). These pulling forces result from the action of cortical force generators, with a larger number of active cortical force generators pulling on astral microtubules of the posterior aster (Grill et al., 2003). While the generation of these pulling forces is known to require the alpha subunit of heterotrimeric G proteins and their activators (Colombo, 2003), the mechanical basis of cortical force generators is not known. By analogy with mechanisms driving chromosome segregation and after precedent in budding yeast, pulling forces could be generated by cortically tethered cytoplasmic dynein and/or microtubule depolymerization-coupled movements. To determine whether dynein is implicated, we compromised the dynein heavy chain DHC-1 using temperature sensitive mutants (Hamill et al., 2002). This allowed us to bypass the early requirements of dynein, conduct spindle severing experiments, and thus deduce the extent of pulling forces by measuring the velocities of the liberated spindle poles. Our results suggest that DHC-1 is required, at least in part, for pulling force generation. Furthermore, preliminary evidence using similar approaches indicates that microtubule depolymerization-coupled movements are implicated as well. Thus it appears that both dynein and microtubule depolymerization together generate pulling forces during asymmetric spindle positioning of *C. elegans* embryos.

982

**Microtubule Binding Allows Dynactin to Mediate Microtubule Search-Capture During Mitosis**

J. R. Bader, E. H. Hinchcliffe, P. S. Vaughan, K. T. Vaughan; Biological Sciences, University of Notre Dame, Notre Dame, IN

Microtubule-based motor proteins are critical for many cellular processes including cell division. A number of microtubule-based motor proteins have been identified that function in mitosis, including cytoplasmic dynein. Cytoplasmic dynein and its receptor complex, dynactin, are thought to be a critical component at spindle poles, the cell cortex, and kinetochores during mitosis. Disruption of any one component is believed to lead to a missegregation of chromosomes, which is now recognized as a primary mechanism of cancer initiation. We have proposed a model of microtubule search-capture at the cell cortex and kinetochores during mitosis, which is mediated by dynactin and coupled to dynein based transport. Dynactin has two important functions during mitosis: binding to microtubules through $p150^{Glued}$ and recruitment of cytoplasmic dynein. To determine the sequence of dynactin functions, we are perturbing protein regulation, function, and expression. Previous work has shown that treatment of cells with forskolin diminishes the microtubule binding ability of the $p150^{Glued}$ subunit of dynactin during interphase. Forskolin stimulates the activity of PKA which phosphorylates the MT-binding domain of $p150^{Glued}$. Live-cell imaging of stably transfected GFP-tubulin BSC-1 cells and immunofluorescence of COS-7 cells treated with forskolin was performed to assess the role of $p150^{Glued}$ during mitosis. Loss of MT-binding through $p150^{Glued}$ resulted in multi-polar spindles, distorted spindles, and lagging chromosomes, suggesting that microtubule search-capture is inhibited at the cell cortex and kinetochores. To confirm that these observed defects are a result of diminished MT-binding through dynactin, we performed siRNA and rescue experiments which suggest multiple roles for dynactin during mitosis. Supported by NIH GM60560.

983

**Identification of Dynein/Dynactin in a Biochemical Screen for Microtubule-Actin Crosslinking Proteins and Probing its Role in Cell Motility**

O. C. Rodriguez, C. M. Waterman-Storer; Cell Biology, The Scripps Research Institute, La Jolla, CA

Interactions between microtubules (MTs) and F-actin are important for dynamic polarized cell behaviors such as directed motility. To identify candidate proteins for mediating MT/F-actin crosslinking interactions, we purified them from HeLa cells by sequential affinity to MTs and F-actin, followed by mass spectrometry. Two of the identified polypeptides were the heavy and intermediate chains of cytoplasmic dynein. Cytoplasmic dynein and its interacting partner, dynactin, are a minus-end MT motor complex that participates in many MT-based motility events. We tested the role of dynein/dynactin in mediating MT/F-actin interactions by interfering with dynein/dynactin function via p50/dynamitin overexpression in migrating Ptk1 epithelial cells and NIH3T3 fibroblasts. First we analyzed the effect on the dynamics and organization of MTs and F-actin labeled with spectrally distinct fluorophores by dual wavelength Fluorescent Speckle Microscopy. In Ptk1 cells overexpressing p50-GFP, dual-wavelength kymograph analysis of F-actin and MT movements revealed a ~30% increase in the rates of F-actin and microtubule flow in the lamella relative to control GFP-injected cells, but no obvious disruption of MT/F-actin structural interactions. Thus in Ptk1 cells dynein/dynactin inhibition did not appear to uncouple MTs from F-actin retrograde flow. We next examined the role of dynein/dynactin in centrosome orientation during cell migration. Using overexpression of another dynactin subunit, p62, we found that although p50-GFP overexpression perturbs centrosome reorientation in a wound assay of NIH3T3 cells, as was previously known, GFP-p62 overexpression did not. Current experiments focus on determining if p50 and p62 overexpression have differential effects on cell migration.

984

**The Affinity of the Dynein Microtubule-Binding Domain is Modulated by Changes in Helical Register of its Full-Length Coiled-Coil Stalk**

J. E. Garbarino, C. E. Tan, I. R. Gibbons; Molecular and Cell Biology, University of California Berkeley, Berkeley, CA

The microtubule binding domain (MTBD) of dynein is separated from the AAA core of the motor by an ~15 nm stalk that is predicted to consist of an anti-parallel coiled coil. The structure of this coiled-coil and the mechanism by which it mediates communication between the MTBD and ATP-binding core are unknown. To identify the optimal alignment between the hydrophobic heptad repeats in the two strands of the stalk coiled-coil, we fused the MTBD of dynein, together with 12-36 residues (~25%) of its stalk, onto a stable coiled-coil base, provided by *Thermus thermophilus* seryl tRNA-synthetase (SRS). By assaying these chimeric constructs for microtubule binding in vitro, we identified an optimal register with 22 residues and 19 residues in the upstream and downstream strands of the coiled coil, respectively, (SRS-22:19) that yielded a protein possessing high-affinity (2.2 μM) for microtubules. Two approximately full-length stalk constructs with this same register of coiled coil strands (SRS-85:82 and SRS-99:96) showed a similarly high affinity at room temperature. Other register alignments generated by adding or deleting one or more

residues from the upstream strand of the full length constructs had ~10-fold lower affinity. This agrees with data from the SRS-22:19 construct and supports the hypothesis that dynein utilizes small amounts of sliding displacement between the two strands of its coiled-coil stalk as a means of communication between the AAA core of the motor and the MTBD. The binding of full-length constructs approximately doubled when the temperature was decreased from 37°C to 4°C, whereas that of SRS-22:19 was little changed, consistent with transitions between high and low affinity forms of the MTBD at physiological temperatures involving shifts in equilibrium between multiple allosteric forms of the full-length stalk.

**Dissection of Intra-molecular Communications between the ATPase Site and Microtubule-binding Site in the Dynein Heavy Chain**

T. Kon, K. Imamura, R. Ohkura, K. Sutoh; Department of Life Sciences, Graduate School of Arts and Sciences, University of Tokyo, Tokyo, Japan

Cytoskeletal motor proteins utilize bidirectional intra-molecular communications between the track-binding site and ATPase site to exert their motile activities. The information on ATP hydrolysis at the ATPase site is transmitted to the track-binding site to modulate the track-binding affinity. Conversely, the status of track binding is communicated to the ATPase site to regulate the rate of the ATPase activity. Elucidation of the mechanism of these intra-molecular communications is a key to understanding how motor proteins exert motile actions along cytoskeletal tracks. As for dynein, a microtubule-based motor protein, its ATPase site(s) is located within the head domain containing six AAA+ modules, while the microtubule-binding site called stalk head is spatially separated from the head domain by a 10-15 nm slender stalk that is predicted to be formed from an antiparallel coiled coil. Therefore, the information at the ATPase site and microtubule binding site of dynein must be transmitted through the stalk coiled coil. However, the mechanism underlying the bidirectional communications remains unclear. To address this issue, we introduced mutations into the stalk head and/or stalk coiled coil of the dynein motor domain. The resultant mutant dyneins can be classified into two groups on the basis of their biochemical properties: the mutant dyneins in the first groups appeared to be trapped in an “inactivated state” showing ATPase activity at basal rate (5-15 $s^{-1}$); those in the second group appeared to be fixed in an “activated state” showing much higher ATPase rate (80-120 $s^{-1}$) that is comparable to the maximum rate of the microtubule-activated ATPase activity of wild type dynein. Based on these results, we propose that dynein utilizes small conformational changes at the stalk coiled coil to couple microtubule binding and ATPase activity.

986

**Characterization of Dynactin Complex in Budding Yeast**

J. Li, J. A. Cooper; Cell Biology and Physiology, Washington University in St. Louis, St. Louis, MO

Dynactin is a multi-subunit protein complex required for most dynein activities, proposed to serve either as a cargo adaptor or to enhance dynein motor processivity. Dynactin consists of two parts with eleven different polypeptides. 1) The actin-like Arp1 filament has conventional actin and capping protein at its barbed end and Arp11, p25, p27, and p62 at its pointed end. 2) The arm consists of $p150^{Glued}$, dynamitin, and p24/22. In *Saccharomyces cerevisae*, homologues of several dynactin subunits have been identified, and deletion of their genes produces phenotypes identical to those of dynein null mutations. On the other hand, homologues for p24/22, p25, p27 and p62 have not been identified, and the composition of yeast dynactin has not been defined biochemically. Here, we report the discovery of an apparent p24/22 homolog in budding yeast, based on the following: 1) The null mutant has a dynein-like phenotype for spindle movement. 2) The predicted polypeptide has an appropriate size and secondary structure. 3) The null mutant is synthetic with kar9 null but not dyn1 null. 4) The protein localizes to microtubule plus ends and the spindle pole body, as seen for Nip100 / $p150^{Glued}$. 5) Dynein accumulates of dynein at the plus end of microtubules in the null mutant, as seen with known dynactin mutants. Biochemical fractionations of intact dynactin complex are underway, which may identify other subunits of yeast dynactin. Based on our current understanding, dynactin is needed to offload dynein from the plus ends to the cortex.

**Dynein Supports Rapid Spindle Elongation in Anaphase B in the Fungus Ustilago maydis**

G. Fink,[1] J. Colombelli,[2] E. H. K. Stelzer,[2] G. Steinberg[1]; [1]Organismic Interaction, Max Planck Institute for Terrestrial Microbiology, Marburg, Germany, [2]Light Microscopy Group, European Molecular Biology Laboratory (EMBL), Heidelberg, Germany

In animal cells spindle elongation in anaphase B is mediated by cytoplasmic dynein, which interacts with the cell cortex and is thought to exert pulling forces on astral microtubules (MTs). In contrast, in the model fungi Saccharomyces cerevisiae and Schizosaccharomyces pombe dynein has no obvious role in anaphase B. Here we describe the role and dynamic rearrangement of dynein in anaphase in Ustilago maydis. During the initial phase spindles elongate at ~1,23 µm/min and no dynein is found at the tips of astral MTs. When the spindle reaches a length of ~2 µm, spindle elongation rates increase to ~5,34 µm/min, which coincides with cortical sliding of astral MTs and rapid motion of the spindle. In conditional dynein mutants spindle initial elongation was normal, but neither cortical sliding of astral MTs, nor rapid elongation was found. Instead, spindles continued elongation at ~1,44 µm/min until they reach a length of ~9 µm, suggesting that dynein-independent forces mediate anaphase A, while anaphase B is driven by dynein. This notion is supported by the observation that dynein is absent from short spindles (up to ~2µm). Dynein appearance coincides with the formation of a single leading MT at both poles of the spindle that carries the strongest dynein signal which is reduced in dynamic instability. Cortical sliding of this MT goes with off-loading of plus-end located dynein at the cell cortex, suggesting that dynein-mediated cortical sliding exerts forces on the spindle. This notion is supported by the observation that a laser-induced cut of the spindle or the cleavage of the sliding MT results in rapid motility of both spindle-halves or the leading MT, respectively. Our data demonstrate that dynein provides the force for rapid spindle elongation in anaphase B in U. maydis.

***Tetrahymena thermophila* Dynein 2 Light Intermediate Chain (D2LIC) Contributes to but is not Essential for Intraflagellar Transport**

V. Rajagopalan,[1] D. E. Wilkes,[2] D. J. Asai[2]; [1]Department of Biological Sciences, Purdue University, West Lafayette, IN, [2]Department of Biology, Harvey Mudd College, Claremont, CA

Cells with cilia or flagella express two non-axonemal (“cytoplasmic”) dyneins, dynein-1 and dynein-2. Dynein-2 heavy chain (Dyh2) is required for retrograde intraflagellar transport (IFT). Dynein-2 is thought to be comprised of only two subunits, the Dyh2 heavy chain and the dynein-2 light intermediate chain (D2LIC). To understand the function of dynein-2 in *Tetrahymena*, we have characterized D2LIC. *Tetrahymena* expresses a single D2LIC gene and the predicted protein is 474 amino acids in length. *Tetrahymena* D2LIC shows 22% and 27% identity to D2LICs from

*Chlamydomonas* and human respectively. We have made knockout heterokaryons of D2LIC; the progeny of two heterokaryons completely lack the D2LIC gene in their somatic macronuclei (KO-D2LIC). KO-D2LIC cells have cilia but exhibit motility defects. KO-D2LIC cells have generation times 1.4 times longer, indicating compromised "rotokinesis", which is required for the completion of cytokinesis (Brown et al., 1999). KO-D2LIC cells swim 3.7 times slower than the wild type controls, and do not swim straight. Despite the presence of an oral apparatus, most of the KO-D2LIC cells fail to phagocytose fluorescent beads, indicating impaired ciliary activity. The KO-D2LIC culture changed with time. Early exconjugants included a significant number of multi-nucleated, very large "monster" cells. Several days later, these "monster" cells were far fewer. Early exconjugants had a high number of multiple micro- and macro-nuclei per cell; the proportion of abnormally nucleated cells decreased after several days. These results are consistent with *Tetrahymena* D2LIC being important but not essential for IFT. *Tetrahymena* D2LIC may serve to stabilize the dynein-2 heavy chains and thus increase the efficiency of retrograde IFT process. (Supported by grants from the National Science Foundation).

## Microtubule Dynamics & Assembly I (989-1010)

989

### Function of the GammaTuRC in Centrosomal and Chromatin-Mediated Microtubule Nucleation

J. Luders, T. Stearns; Biological Sciences, Stanford University, Stanford, CA

During Interphase the gamma-tubulin ring complex (gammaTuRC), the major microtubule nuleator in animal cells, is found at the centrosomes and in the cytoplasm. At the G2/M transition additional gamma-tubulin from the cytoplasm is recruited to the centrosomes. Microtubule nucleation by the gammaTuRC is important for the formation of the mitotic spindle and recruitment of gammaTuRC to mitotic centrosomes is most likely regulated by kinases. At metaphase the gammaTuRC localizes not only to the spindle poles but also to spindle microtubules. We have identified and characterized a new subunit of the human gammaTuRC which regulates gammaTuRC localization and is required for centrosomal and chromatin-mediated microtubule nucleation. Our data provides new insight into functions of the gammaTuRC other than its well established role in microtubule nucleation at the centrosome.

### Structural Properties and Microtubule-Nucleating Activity of Human γ-Tubulin

M. Moritz,[1] L. Rice,[2] K. Yonekura,[1] H. Aldaz,[1] M. Braunfeld,[2] T. Stearns,[3] D. A. Agard[2]; [1]Biochemistry & Biophysics, UCSF, San Francisco, CA, [2]Biochemistry & Biophysics, UCSF, HHMI, San Francisco, CA, [3]Biological Sciences, Stanford University, Stanford, CA

γ-Tubulin is the major component of the 2.2 MDa γ-tubulin ring complex, and is the key microtubule-nucleating protein in cells. Although structurally similar to α/β-tubulin, γ-tubulin exhibits very distinct oligomerization properties and can nucleate microtubules on its own in vitro from pure components. We are characterizing γ-tubulin's unique assembly properties and its interaction with α/β-tubulin using electron microscopy, helical reconstruction, and various hydrodynamic techniques. We have found that pure γ-tubulin exists as a monomer in 0.5M KCL, but in low salt it rapidly forms distinct oligomers ranging from tetramers to long filaments to sheets/tubes, depending on concentration, pH and the presence or absence of α/β-tubulin. Interestingly, unlike α/β-tubulin, γ-tubulin oligomerization does not depend on GTP or temperature. We are also exploring γ-tubulin's microtubule-nucleating activity in molecular detail using light-scattering assays and kinetic modeling. At low concentrations (60-100nM), γ-tubulin appears to accelerate the rate of nucleus formation rather than decreasing the nucleus size. The nucleation mechanism appears to change at a higher concentration of γ-tubulin (600-700nM), where it forms larger oligomers. This suggests that larger oligomers of γ-tubulin are more potent nucleators, apparently acting by stabilizing smaller oligomers of α/β-tubulin and thus decreasing the nucleus size. Oligomerization-dependent nucleation mechanisms should help us to understand the nucleation mechanism of the γ-tubulin ring complex, which likely contains 12 or 14 γ-tubulins.

991

### Structural Analysis of Recombinant Yeast Small Gamma-Tubulin Complex

A. Zelter,[1] L. M. Rice,[2] E. Muller,[1] B. Fox,[1] J. W. Kern,[1] D. A. Agard,[2] T. N. Davis[1]; [1]Department of Biochemistry, University of Washington, Seattle, WA, [2]Howard Hughes Medical Institute and Department of Biochemistry and Biophysics, University of California at San Francisco, San Francisco, CA

Gamma-tubulin is required for nucleation of microtubules and spindle assembly in eukaryotic cells. It is found in two major complexes, a small complex (~11 S) and a large complex (~25 S). In yeast and other eukaryotic cells, the small complex contains two related proteins, (Spc97 and Spc98 in yeast) and gamma-tubulin (Tub4 in yeast). The stoichiometry is 2 Tub4 : 1 Spc97 : 1 Spc98 (Vinh et al., 2002). We expressed the yeast small complex in insect cells and analyzed the recombinant small complex by several methods. First, scanning transmission electron microscopy revealed triangular shaped structures of the approximate molecular mass expected for the small complex. Then the structure of the purified recombinant small Tub4-complex was determined to 25 Å resolution by single particle reconstruction of negative stained material. This higher resolution structure clearly revealed a Y-shaped complex. This is the first structure available for a small gamma-tubulin complex from any organism. The organization and orientation of the components in the Y is not known. Two gamma-tubulins modeled from the recent crystal structure of human gamma-tubulin (Aldaz et al., 2005) fit into the top of the Y structure. Since either Spc97 or Spc98 will form a complex with Tub4, one possibility is that Spc97 and Spc98 form the base of the Y with each one binding to one of the Tub4s in the arms. Vinh, D. B. N., J. W. Kern, W. Hancock, J. Howard and T. N. Davis (2002) Reconstitution and characterization of the budding yeast gamma-tubulin complex. Mol. Biol. Cell 13:1144-1157. Aldaz H., L. M. Rice, T. Stearns, D. A. Agard (2005) Insights into microtubule nucleation from the crystal structure of human gamma-tubulin. Nature 435:523-527.

### Insight into Microtubule Assembly from the Atomic Structure of Human Gamma-tubulin

L. M. Rice,[1] H. Aldaz,[2] T. Stearns,[3] D. A. Agard[1]; [1]Biochemistry, UC San Francisco, San Francisco, CA, [2]MCB, UC Berkeley, Berkeley, CA, [3]Biological Sciences, Stanford University, Stanford, CA

Microtubules are hollow polymers of αβ-tubulin that exhibit GTP-dependent assembly dynamics and comprise a critical part of the eukaryotic

cytoskeleton. Initiation of new microtubules *in vivo* requires γ-tubulin, organized as an oligomer within the γ-Tubulin Ring Complex (γ-TuRC) of higher eukaryotes. Structural insight into γ-tubulin, its oligomerization, and how it promotes microtubule assembly remains lacking. We have determined the 2.7Å crystal structure of human γ-tubulin bound to GTPγS. One of the crystal packing interactions recapitulates the lateral contacts between tubulins in the microtubule lattice and probably forms the basis for γ-tubulin oligomerization within the g-TuRC. Unexpectedly, γ-tubulin:GTPγS adopts a curved conformation very similar to that seen in GDP-bound microtubule depolymerization products. This suggests that, unlike signaling GTPases, tubulins may not undergo nucleotide-dependent conformational switching. To confirm the idea that nucleotide state does not directly regulate the conformation of αβ-tubulin, we demonstrated that allocolchicine binds αβ-tubulin:GTP and αβ-tubulin:GDP with essentially identical affinity. These results have important implications for αβ-tubulin assembly; in particular, they suggest that there are unanticipated barriers to *de novo* microtubule assembly. We propose a model for microtubule assembly in which guanine nucleotides do not regulate curved-to-straight transitions, but instead serve to modulate the strength of longitudinal interactions within the microtubule lattice.

993

**Multiple Mechanisms for Microtubule Generation and Pole Focusing of the Mitotic Spindle**

G. Goshima,[1] N. M. Mahoney,[1] F. Nedelec,[2] R. D. Vale[1]; [1]Cellular and Molecular Pharmacology, UCSF, San Francisco, CA, [2]EMBL, Heidelberg, Germany

During the formation of metaphase spindle in animal somatic cells, microtubules (MTs) are generated from centrosomes (C-MTs) and chromosomes. These two MT networks need to be interconnected and focused by minus-end-directed motor proteins to create the diamond-shaped appearance of the bipolar spindle. We have characterized the roles of two minus-end-directed motors, dynein and Ncd, in such processes in Drosophila S2 cells using RNAi and high resolution microscopy. While the motors have overlapping functions, we show that Ncd is primarily responsible for focusing kinetochore microtubule bundles (K-fibers), while dynein has dominant function in transporting the K-fibers to the centrosomes. We also report a novel localization of Ncd to the growing tips of C-MTs, which we show is mediated by the plus-end-tracking protein EB1. Computer modeling of the pole focusing process suggests that the plus end localization of Ncd could facilitate the capture and transport of K-fibers along C-MTs. From these results and simulations, we propose a model on how two minus-end-directed motors cooperate to ensure spindle pole coalescence during mitosis. We also investigated the mitotic function of 28 genes implicated in centrosome function in S2 cells and identified several proteins as yielding pronounced mitotic spindle defects after RNAi depletion. Live cell imaging of GFP-tubulin demonstrated that γ-tubulin is required for generation of both C-MTs and chromosomal MTs. By tracking analysis of EB1-GFP, we also uncovered another process of MT formation originating from spindle microtubules possibly in a γ-tubulin independent manner. We speculate that such de novo MT growth may involve a novel mechanism of templating from pre-existing MTs.

994

**Mechanisms for Mitotic Spindle Pole Focusing in the Absence of Functional Centrosomes**

G. Goshima, A. Kirby, H. Barak, L. Krueger, S. Sivaramakrishnan, R. D. Vale; Physiology Course 2005, Marine Biological Laboratory, Woods Hole, MA

The centrosome is the dominant microtubule (MT) nucleation site during mitotic spindle formation. However, animal somatic cells also can generate MTs near chromosomes independently of centrosome function. In Drosophila S2 cells, RNAi of centrosomin (CNN) leads to loss of functional centrosomes, and spindles MTs are generated and organized into a bipolar array via chromatin-dependent pathway, as occurs during meiosis. Despite the absence of functional centrosomes, the spindle MTs, including kinetochore microtubule bundles (K-fiber), are reasonably well focused at their minus-ends in CNN RNAi cells. To understand the mechanism of K-fiber focusing in the absence of centrosomes, we performed double RNAi screening of CNN with ~200 known mitotic genes, and identified Ncd (a minus-end-directed kinesin) and Asp (a putative homolog of vertebrate NuMA) as essential factors for K-fiber focusing in CNN spindle. Interestingly, unlike what has been described for meiotic spindles reconstituted using Xenopus egg extracts, RNAi knockdown of dynein/dynactin subunits did not affect the pole focusing of acentrosomal spindles in S2 cells. We suggest that pole focusing by dynein requires a centrosome and involves to transport K-fibers along centrosome MTs. Ncd and Asp, on the other hand, can crossbridge minus ends of K-fibers and contribute to pole focusing in the absence of centrosomes.

995

**Microtubule Flux in Early Mitosis**

N. P. Ferenz, P. Wadsworth; Biology, University of Massachusetts, Amherst, MA

To date, the study of microtubule flux during mitosis has been limited to metaphase and anaphase. Because kinetochore microtubules attach to chromosomes prior to metaphase, we considered the possibility that these fibers may flux during this time. Using a permanent mammalian cell line expressing α-tubulin tagged with a photoactivatable variant of GFP as well as the inner centromere protein CenpA tagged with GFP (LLCPK1-PA-CenpA), we have observed poleward movement of photoactivated regions during prometaphase. Additionally, we have detected similar motions in the centrosomal array of microtubules prior to nuclear envelope breakdown (NEB). These data suggest 1) that microtubule flux may contribute to mitosis in ways previously undetected and 2) a mechanism for kinetochore fiber flux that might differ from the established model, as the antiparallel microtubules necessary for the proposed actions of Eg5 may be unavailable in developing spindles. In order to determine the mechanism responsible for promoting flux at these early stages, photoactivation is being used to analyze flux following siRNA of candidate molecules (Kif2a, Eg5 and MCAK). Although a fully sequenced pig genome is yet to be completed, a large collection of pig ESTs can be found on the NCBI database, including partial sequences for the above listed molecules. The pig sequences for Kif2a and Eg5 are identical in the regions used for siRNA of human Kif2a and Eg5, and siRNA of pig Eg5 generates a monopolar phenotype. Thus, we can deplete candidate genes and directly observe microtubule behavior during spindle formation. Our observations suggest that mitotic microtubules undergo poleward flux during prophase and prometaphase in mammalian cells.

996

**Examining the Function of Microtubule Localized RNAs during Mitosis**

M. D. Blower, K. Weis, R. Heald; Department of Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA

Accurate segregation of chromosomes during mitosis and meiosis is required for organismal development and viability, and depends on the assembly and function of a dynamic mitotic spindle that orchestrates chromosome movements. Previous work has demonstrated that several proteins involved in RNA metabolism (Rae1, Maskin, and CPEB) are localized to the mitotic spindle and contribute to spindle assembly. Furthermore, we have shown that RNA itself is localized to mitotic microtubules in *Xenopus* egg extracts, and contributes to spindle assembly in a translation independent manner that may reflect a structural role. We have found that several different types of microtubule-associated RNA are present on the spindle including ribosomal RNA and messenger RNA (MT-mRNA). We have used Affymetrix gene chip microarrays to determine which mRNAs are specifically enriched on the mitotic spindle. While translation of RNA is not required for spindle assembly in egg extracts, our preliminary results suggest that translation of a subset of MT-mRNAs contributes to mitotic progression, while a distinct subset of MT-mRNAs are found in inactive storage granules likely to function later in development. We will present evidence that translation of a key cell cycle regulator is required for exit from a Spindle Assembly Checkpoint (SAC) induced mitotic arrest, suggesting that mitotic translation is regulating anaphase onset. We will also present the results of experiments investigating how MT-mRNAs are targeted to the spindle, and the functional importance of spindle-localized protein translation. These experiments should provide insight into the role of MT-mRNAs during mitosis and development.

997

**Microtubules and Interphase Cell Cycle Progression**

Y. Uetake, G. Sluder; UMass Medical School, Worcester, MA

The importance of cytoplasmic microtubules for interphase cell cycle progression in mammalian somatic cells has been unclear due to the diversity of published experimental results. We use normal human primary fibroblasts and hTERT-RPE1 cells to systematically investigate the involvement of cytoplasmic microtubules in interphase cell cycle progression. We affect a complete and rapid disassembly of microtubules at anaphase-telophase by treating mitotic shake off cells for 10 min. at 0 °C followed by continuous exposure to 3.2 uM nocodazole. We find that the cells complete mitosis and progress through interphase with normal kinetics into the next mitosis, at which point they arrest due to microtubule absence. In separate experiments we quantitatively examine the relationship between prolongation of mitosis and subsequent G1 progression. We prolong mitosis with low dose (0.08 uM) nocodazole that leave small bipolar spindles or disorganized spindles. Upon release from nocodazole the cells divide in a normal bipolar fashion regardless of the mitotic durations examined. If mitosis is prolonged less than ~45 minutes, the cells progress through interphase into the next mitosis with normal kinetics. If the block is longer than ~1 hour, the cells arrest in G1 for at least 48 hr. Similar results were obtained using 100 uM monastrol to prolong mitosis by preventing spindle bipolarization. Prolongation of mitosis by less than 1 hour allows the cells progress through interphase into the next mitosis with normal kinetics while longer delays lead to a G1 arrest. We conclude that cytoplasmic microtubules have no required function for complete interphase progression in normal, p53 competent human cells. However, modest prolongation of mitosis in the presence of spindle microtubules leads to a G1 arrest once the cells complete an otherwise normal division.

998

**Microtubule and Myosin II Dynamics during Cytokinesis in Echinoderm Embryos**

V. E. Foe; Center for Cell Dynamics, University of Washington, Friday Harbor, WA

Recent studies suggest a positive role for stable microtubules in furrow induction (Shannon et al., 2005; Canman et al., 2003). By treating echinoderm blastomeres for five minutes with 20 uM nocodazole (over 100X the concentration needed to depolymerize most of this cell's microtubules) we have revealed a previously undescribed transient population of stable microtubules, which begins forming at anaphase onset (first near chromosomes), grows out in all directions as anaphase proceeds, by telophase converts into an array roughly coextensive with what is commonly called the "central spindle", and disappears as cell cleavage completes. The time of their formation, their localization, and the finding by others that taxol-stabilized microtubules can induce furrowing (Shannon et al., 2005) leads us to suspect that this nocodazole-resistant array is involved in signaling equatorial RhoA (and myosin II) activation. Using fixed echinoderm blastomeres and an antibody that recognizes the activating phospho-serine19 of RLC we show that activated myosin II (a small fraction of all myosin II) localizes to the cortex, waxing and waning in phase with the cell cycle. Upon metaphase exit there is a brief large-scale increase in phospho-serine19 RLC over the entire cell cortex. Then as dynamic elongating astral microtubules reach the cortex in anaphase/telophase (initially before stable microtubules make contact) there ensues a progressive global diminution of activated cortical myosin II, possibly because microtubules remove it or microtubule polymerization modulates Rho signaling. Nocodazole treatment during early anaphase that eliminates dynamic astral microtubules before cortical phospho-serine19 MRLC diminution, inhibits or slows furrowing and either leaves the whole cell surface myosin-enriched or widens the contractile furrow. Our findings suggest a mechanism whereby dynamic microtubule outgrowth induces polar relaxation (except that relaxation is global not just polar) while stable microtubules signal myosin recruitment to the furrow.

999

**G Protein-coupled Receptors Activation Induces Gβγ Translocation and Promotes Microtubule Assembly in NIH3T3 Cells**

C. Gutierrez, S. Das, S. Roychowdhury; Biological sciences, University of Texas at El Paso, El Paso, TX

βγ subunit of G proteins is known to transfer signals from cell surface receptors to intracellular effector molecules. Recent genetic analyses of *C. elegans* and *Drosophila* reveal that Gβγ is also involved in regulating mitotic spindles. Previously we have shown that βγ subunit of G proteins promotes microtubule assembly in vitro [Roychowdhury and Rasenick (1997*) J. Biol. Chem.* 272, 31476-31581]. Gβγ was found to interact preferentially with microtubules (rather than tubulin dimers) in both NIH3T3 and PC12 cells. Using microtubule-acting drugs, Gβγ was shown to be involved in microtubule assembly. To further elucidate the possible link between G protein activation and microtubule modulation by Gβγ, NIH3T3 cells were treated with isoproterenol, an agonist for β-adrenergic receptors (cell surface receptors linked to Gs) and UK14,304, an agonist for α2- adrenergic receptors (cell surface receptors linked to Gi) for 1h. After agonist treatment, cytoskeletal fraction (enriched in microtubules) and soluble protein fraction (enriched in tubulin dimer) were isolated. Gβγ association with microtubules and soluble tubulin fractions as well as the changes in microtubule assembly was determined. Both isoproterenol and UK14,304 increased the Gβγ association with microtubule fraction by ~75%. In addition, promotion of microtubule assembly and/or stabilization of microtubules was observed in the presence of both agonists (~50%). Since activation of both Gs and Gi produced similar effects, the possible involvement of cAMP in this process was ruled out. Our result suggests that G protein-coupled receptors are involved in the modulation of microtubules by mobilizing Gβγ to bind to tubulin/microtubules.

1000

**CLASP-Dependent Nucleation Contributes to the Asymmetry of Microtubule Arrays**

A. Kharitonov,[1] N. Andreeva,[1] A. Efimov,[2] A. Khodjakov,[3] N. Galjart,[4] J. V. Small,[1] A. Akhmanova,[4] I. Kaverina[2]; [1]IMBA, Vienna, Austria, [2]Vanderbilt University Medical Center, Nashville, TN, [3]Wadsworth Center, Albany, NY, [4]Erasmus University, Rotterdam, The Netherlands

Microtubules differentially regulate the front and the rear of motile cells due to the dynamic asymmetry of their system. As microtubule nucleation at the centrosome is symmetric, other mechanisms are responsible for differential changes in microtubule system. CLASPs are microtubule tip-binding proteins that also localize to centrosome and Golgi apparatus, sites capable of the microtubule nucleation and anchoring. We studied the role of CLASPs in microtubule nucleation at Golgi complexes and in the microtubule pattern. We analyzed microtubule plus ends dynamics in the cell center by video imaging of GFP-EB3 expressing motile cells. Microtubule outgrowth started at centrosome or Golgi membranes. While centrosomal nucleation was symmetric, Golgi-associated microtubule array was not. Further, we used siRNA approach to investigate the role of CLASP in microtubule nucleation. CLASP depletion blocked Golgi-associated microtubule outgrowth. Dense microtubule meshwork, characteristic for Golgi region, is absent in CLASP-depleted cells, indicating disturbed microtubule-Golgi association. Microtubule re-growth assay upon nocodazole washout confirmed that CLASPs were essential for initiation of microtubules at Golgi. Our data indicate that CLASPs participate in nucleation and/or stabilization of microtubule minus ends at Golgi membranes. We propose that this novel CLASP function is essential for the asymmetry of microtubule arrays in motile cells.

1001

**The Fission Yeast CLASP Homolog Promotes Stability of Interphase Microtubules**

S. V. Bratman, F. Chang; Microbiology, Columbia University, New York, NY

CLIP-associated proteins (CLASPs) constitute a family of microtubule-associated proteins conserved from yeasts to mammals. Recent studies have suggested roles for CLASPs in regulating microtubule dynamics at kinetochores in mitosis and at the cell cortex in interphase. Here we characterize the single CLASP homolog in the fission yeast *Schizosaccharomyces pombe.* CLASP overexpression produces a novel phenotype on interphase microtubule dynamics. Microtubules are properly organized and extend the length of the cell, but appear to be excessively stable and bundled. In contrast to normal microtubules, which rarely display rescue, in cells overexpressing CLASP, microtubules grow and shrink in only very small excursions at the cell tips, indicative of increased microtubule rescue frequency. These effects on microtubule plus-end dynamics are independent of tip1p (CLIP170), mal3p (EB1) and mto1p (γ-TuC). CLASP may also stabilize MT minus-ends, as treadmilling microtubules in the γ-TuC mutant *mto1Δ* become less dynamic upon overexpression of CLASP. When expressed at endogenous levels, CLASP localizes primarily to peri-nuclear dots on interphase microtubules and to regions of the mitotic spindle, although when overexpressed, it decorates entire microtubules. Analyses of loss-of-function mutants will also be presented. These studies suggest that fission yeast CLASP may play a direct role in the regulation of microtubule stability.

1002

**The Role of β-catenin/APC Interactions in Microtubule Dynamics**

R. K. Louie, S. Bahmanyar, W. J. Nelson, A. I. M. Barth; Molecular and Cellular Physiology, Stanford University School of Medicine, Stanford, CA

β-catenin and the adenomatous polyposis coli (APC) tumor suppressor protein are important components in the Wnt signal transduction pathway. In this pathway, β-catenin stability is regulated by the state of phosphorylation by the kinase GSK-3β. Mutations in these proteins are implicated in cancers, including breast and colorectal carcinomas. In addition to the Wnt pathway, APC also plays a role in microtubule organization and cell migration. We have begun to explore structural roles of β-catenin binding to APC in the regulation of microtubules in cells expressing mutant β-catenin that cannot be phosphorylated by GSK-3β. This stabilized form of β-catenin localizes prominently to APC clusters at the tips of membrane extensions. Live cell imaging of GFP-tubulin reveals a decrease in the dynamic instability of microtubules in cells expressing this stabilized β-catenin. Microtubules in these cells spend more time in pause, and are noticeably less dynamic at the cell edge. Current work aims at elucidating the mechanism by which β-catenin binding to APC regulates the microtubule cytoskeleton.

1003

**Apc Protein Modulates Local Microtubule Assembly/disassembly Dynamics Independently of Eb1**

K. Kita,[1] T. Wittmann,[1] I. S. Näthke,[2] C. M. Waterman-Storer[1]; [1]Department of Cell Biology, The Scripps Research Institute, La Jolla, CA, [2]Division of Cell & Developmental Biology, University of Dundee, Dundee, United Kingdom

Regional regulation of microtubule (MT) assembly/disassembly dynamics is critical to polarized cell behaviors such as directional migration, neuronal pathfinding, and the immune response. In interphase cells, the adenomatous polyposis coli (APC) protein accumulates on a small subset of MTs in cell protrusions. This implies that APC may be involved in regulating the assembly/disassembly dynamics of these specific MTs. To test this hypothesis, we used a fluorescently labeled monoclonal antibody that recognizes an N-terminal APC epitope to act as a non-perturbing probe to visualize dynamics of endogenous APC and MTs labeled with a spectrally distinct fluorophore in living cells. Analysis of APC-decorated and non-APC-decorated MT plus ends revealed that MTs decorated with APC spent more time growing and had a decreased catastrophe frequency than neighboring MTs in the same cell not decorated with APC. We also made the novel discovery that endogenous APC could associate with shortening MTs. To determine the relationship between APC and its binding partner EB1, we monitored EB1-GFP and endogenous APC concomitantly in living cells. Only a small fraction of APC co-localized with EB1 at any one time. Using APC-deficient cell lines and siRNA of EB1, we found that EB1and APC localized at MT ends independently. Depletion of EB1 did not change the growth-stabilizing effects of APC decoration on MT plus ends. In addition, EB1 immediately dissociated from MT plus ends after cells were treated with submicromolar concentrations of nocodazole, while APC did not. Our observations demonstrate for the first time that the association of endogenous APC protein correlates directly with increased MT growth stability independent of its association with EB1, and show that APC and EB1 associate with MT plus ends by distinct mechanisms.

1004

**Molecular Dynamics Imaging in Micro-patterned Living Cells**

K. Kandere-Grzybowska,[1] C. Campbell,[2] Y. Komarova,[1] O. Chaga,[1] B. Grzybowski,[2] G. G. Borisy[1]; [1]Cell and Molecular Biology, Northwestern University Medical School, Chicago, IL, [2]Department of Chemical and Biological Engineering, Northwestern University, Evanston, IL

A hallmark of cancer metastasis is activation of cell motility machinery leading to cell movement and invasion. Generating cells of uniform shape and predictable cytoskeletal organization by substratum micro-patterning techniques would enable quantitative analysis of cell motility subcomponent processes. Current micro-patterning approaches using self-assembled monolayers of alkyl thiols on gold are incompatible with important imaging modalities in cell biology because of absorption of light and scattering of electrons by gold. Here, we describe a novel procedure--Anisotropic Solid Microetching (ASOMIC)--that overcomes these limitations. ASOMIC employs reaction-diffusion processes in patterned agarose stamp to microetch a uniform gold layer that is subsequently rendered anti-adhesive. The method allows molecular dynamics imaging by wide-field and total internal reflection fluorescence (TIRF) microscopy of living cells and correlative platinum replica electron microscopy. Microtubule (MT) dynamics was investigated in B16F1 mouse melanoma cells from time-lapse series of yellow-fluorescent protein fusion with MT plus-end cytoplasmic linker protein-170 (YFP-CLIP170). Upon impact with cell edge, MTs often turned and continued to grow along it. While cell shape had no significant effect on MT growth velocity or growth persistence, “edge impact” turning behavior was dependent on the shape of cell edge--MTs turned more frequently when encountering straight edges of triangular cells, rather than convex perimeters of circular cells. Initial results with triangular cells suggest a pathway for guidance of MT growth. This method allows for high-resolution dynamic imaging of fluorescently-labeled molecules in geometrically-defined, living cells and is compatible with other important imaging modalities. It is likely to be of broad applicability to cell biology, especially to understanding control mechanism of directional cell motility and cancer metastasis. **In Vitro Reconstitution with CLIP-170, EB1 and p150$^{Glued}$ Demonstrates Distinct Mechanisms of Microtubule Plus-End Tracking**

L. A. Ligon, J. L. Ross, M. K. Tokito, E. L. F. Holzbaur; Department of Physiology, University of Pennsylvania, Philadelphia, PA

Microtubules in the cell are highly dynamic, and microtubule plus-end proteins are important regulators of this behavior. Plus-end proteins dynamically track the tips of growing microtubules *in vivo*, but the mechanisms driving this specific localization are not well understood. Here we used binding experiments, *in vitro* reconstitution, and total internal reflection (TIRF) microscopy with the purified tip-tracking proteins CLIP-170, p150$^{Glued}$, and EB1 to test potential mechanisms for plus-end specific localization. Binding experiments demonstrate that CLIP-170 binds tubulin dimers with an affinity several-fold higher than that for polymerized microtubules. In contrast, p150$^{Glued}$ binds to microtubules with a higher affinity than to tubulin dimers. Under these experimental conditions, EB1 binds weakly to both tubulin and microtubules. *In vitro* reconstitution assays show that CLIP-170 can co-polymerize with tubulin, and polymerization assays with TIRF microscopy demonstrate that CLIP-170 is dynamically associated with microtubule ends. p150$^{Glued}$ and EB1, on the other hand, do not co-polymerize with tubulin, suggesting that they utilize different mechanisms for the robust *in vivo* plus-end localization they demonstrate. Binding experiments show that EB1 can bind to CLIP-170. Further, CLIP-170 can recruit EB1 to tubulin dimers and this complex co-polymerizes with tubulin, suggesting that EB1 may be localized to plus-ends via its association with other plus-end proteins. We have previously shown that EB1 binds directly to p150$^{Glued}$ (Ligon *et al*., Mol Biol Cell, 2003), and here we show that CLIP-170 and p150$^{Glued}$ compete for binding to EB1. These results suggest that there may be multiple microtubule plus-end complexes and these complexes may differentially regulate microtubule dynamics. *Supported by NIH GM48661.*

**Actin-dependent Regulation of Microtubule Dynamics via Interaction between mDia1 Formin and Alpha-tubulin Deacetylase HDAC6**

C. Ballestrem,[1] Y. Zilberman,[2] L. Carramusa,[2] B. Gilquin,[3] M. Shtutman,[2] S. Khochbin,[3] A. D. Bershadsky[2]; [1]Faculty of Life Sciences, University of Manchester, Manchester UK, United Kingdom, [2]Department of Molecular Cell Biology, The Weizmann Institute of Science, Rehovot, Israel, [3]Faculte de Medecine, Institut Albert Bonniot, La Tronche Cedex, France

This study reveals a link between actin cytoskeleton and microtubules mediated by interaction between mDia1 formin and alpha-tubulin deacetylase HDAC6. Expression of a constitutively active form of formin mDia1 not only enhanced actin polymerization but also triggered profound alterations in microtubule dynamics. Measurements of microtubule plus end growth using GFP/RFP-fusion constructs of microtubule end-tracking proteins or alpha-tubulin revealed that active mDia1 decreased the microtubule elongation rate by a half, irrespective of which marker for the growing microtubule was used. This reduction of microtubule growth rate was abolished by treatment with inhibitors of actin polymerization, suggesting that the effect of mDia1 on microtubule dynamics is mediated by actin filaments. We then found a more direct relationship between mDia1 and microtubules. In latrunculin B-treated cells, micron-sized patches containing active mDia1 moved rapidly along microtubules. In cells expressing active mDia1, the fraction of microtubules containing acetylated alpha-tubulin increased dramatically. Since alpha-tubulin acetylation is controlled by its specific deacetylase, HDAC6, we determined whether this enzyme is involved in the mDia1-induced alteration of microtubule dynamics. Co-immunoprecipitation experiments demonstrated that HDAC6 associated with mDia, and both mDia1 and HDAC6 further interact with the plus-end tracking proteins EB1 and Arp1. Blocking HDAC6's deacetylase activity by tubacin or TSA affected microtubule dynamics in the same way as active mDia1. HDAC6-siRNA knockdown experiments showed that HDAC6 is necessary for mDia1 to decrease microtubule growth, while overexpressing wild-type, but not catalytically inactive, HDAC6 partially restored microtubule growth in mDia1-expressing cells. Thus, HDAC6 with inhibited deacetylase function mediates mDia1's effect on microtubules. We conclude that mDia1 and HDAC6 are constituents of a molecular complex responsible for a dynamic link between growing ends of microtubules and actin filaments.

**The Formin mDia Stabilizes Microtubules Independently of Its Actin Nucleation Activity**

F. Bartolini,[1] J. B. Moseley,[2] J. Schmoranzer,[1] B. L. Goode,[2] G. G. Gundersen[1]; [1]Pathology & Cell Biology, Columbia University, New York, NY, [2]Biology, Brandeis University, Waltham, MA

A major microtubule (MT) polarization event in directed cell migration is the Rho-mDia dependent stabilization of a subset of MTs oriented

towards the direction of migration (Palazzo et al., NCB, 2001; Wen et al., NCB, 2004). The stabilization induced by Rho-mDia in vivo is achieved by capping of MT plus ends making them refractory to tubulin subunit exchange. mDia and other formins nucleate actin filaments, yet, it is unclear whether this activity or a separate activity of mDia is involved in MT stabilization. Based upon the crystal structure of the yeast formin Bni1, we prepared two mutants (K853A and I704A) in a constitutively active version of mDia2 and found that these mutants were unable to promote efficient actin nucleation in vitro, to induce actin filaments or filopodia in vivo or to "surf" at the ends of actin filaments in vivo. Strikingly, both these mutants still retained the ability to induce the formation of stable MTs in serum-starved cells and to bind to the MT TIP proteins EB1 and APC. A dimerization mutant of mDia2 (W630A) was also inactive toward actin but retained the ability to generate stable MTs in vivo. These results show that promotion of actin assembly and induction of MT stability by mDia can be functionally separated. In agreement with this, recombinant wild type mDia1, mDia2 and actin nucleation mutants of mDia2 all bound directly to MTs in vitro. Also, the minimally active fragment of mDia2 (containing just FH1 and FH2 domains) inhibited assembly of MTs from tubulin subunits and stabilized assembled MTs from depolymerization in vitro. These results show that the formin mDia has a direct activity to stabilize MTs, perhaps by capping dynamic MT ends.

**Contrasting Actions of SCG10 and Stathmin on Microtubule Dynamic Instability at Steady State in vitro**

T. Manna,[1] D. Thrower,[1] G. Grenningloh,[2] L. Wilson[1]; [1]Molecular, Cellular, Developmental Biology, University of California Santa Barbara, Santa Barbara, CA, [2]Centre de Neurosciences Psychiatriques, University Hospital of Lausanne, Lausanne, Switzerland

Stathmin and SCG10, members of the stathmin family of microtubule (MT) destabilizing proteins, are highly expressed in the developing nervous system. SCG10 is believed to regulate growth cone MT dynamics in response to extracellular signals during axonal growth. While several studies have examined the effects of stathmin on dynamic instability, little is known about how other stathmin family members regulate MT dynamics. We have analyzed the effects of SCG10 (35-179) on dynamic instability *in vitro* and find that its actions are distinct from those of stathmin. At steady state, conditions in which the MT polymer and tubulin concentrations remain constant, stathmin strongly and selectively destabilizes minus ends by increasing the catastrophe frequency. It has little or no effect on the rate or extent of growth or shortening at either end. We further find that stathmin increases the MT treadmilling rate and that it binds to MTs *in vitro* along their lengths. SCG10 regulates dynamic instability differently than stathmin. The major effect of SCG10 at plus ends is to increase the growth rate and the length grown during growth events. Like stathmin, SCG10, increases the plus end catastrophe frequency, but much more weakly than stathmin. The major effect of SCG10 at minus ends is to increase the shortening rate. Like stathmin, SCG10 also increases the minus end catastrophe frequency, but more weakly than stathmin. Like stathmin, SCG10 also binds to MTs along their lengths. The ability of SCG10 to increase plus end growth is consistent with its postulated role in neurite outgrowth (Riederer et al., *Proc. Natl. Acad. Sci.* **94**:741-45, 1997). The results also indicate that an important cellular action of both stathmin and SCG10 may be to destabilize MT minus ends. Supported by NS13560.

**Study of the Function of Wild-type Op18/Stathmin and Mutant Q18→E in Microtubule Polymerization and Dynamics**

H. A. Wilson, D. A. Thrower, L. Wilson; Molecular, Cellular and Developmental Biology, University of California Santa Barbara, Santa Barbara, CA

Stathmin/Op18 is a microtubule destabilizing, ubiquitous, cytosolic protein that is highly expressed in neuronal cells. Much debate has occurred and continues, concerning the actual mechanism utilized by stathmin to inhibit the formation of microtubules by inducing the catastrophe/depolymerization phase in microtubule dynamics. The mechanisms proposed include a "Sequestering "model in which Op18 forms a T2S (tubulin-stathmin-tubulin) complex with tubulin subunits, thus preventing polymerization from occurring, and also a "Binding" model in which Op18 directly binds to microtubule structures to induce depolymerization. While our recent experimental findings are consistent with the both of the proposed mechanisms, we also observed that stathmin is capable of inducing catastrophes independently of sequestration *in vitro*, which we confirmed with a sequestration deficient mutant. A recent study discovered a mutant form of stathmin (Q18→E) in an esophageal adenocarcinoma that possesses the ability to transform normal cells and promote tumor formation. We observed a significantly reduced effect on microtubule polymerization by the Q18→E mutant relative to wild-type stathmin. Another recent study indicated that stathmin deficient mice developed an age-dependent axonopathy of the peripheral and central nervous systems. Our goal is to further understand the role of stathmin in microtubule dynamics by comparing the ability of this mutant and wild-type stathmin to bind to tubulin, to undergo phosphorylation, in addition to a comparison of their effects on microtubule dynamics. Clarification of stathmin's role in microtubule dynamics would facilitate our understanding of its role in diseases in which its expression is elevated such as in various cancers, demyelinating disorders such as multiple sclerosis, and age-related disorders.

**XMAP215 Inhibits the Localization of XKCM1 to Microtubule Ends**

J. H. Stear, G. J. Brouhard, J. Howard, A. A. Hyman; Max-Planck Institute for Cell Biology and Genetics, Dresden, Germany

The *X. laevis* protein XKCM1 belongs to an evolutionarily conserved family of kinesin-like proteins which function in vivo and in vitro as potent microtubule destabilizers. These proteins exhibit a high affinity for microtubule ends, where they catalyze the removal of tubulin subunits and promote catastrophe events. The catastrophe promoting activity of XKCM1 is opposed by XMAP215, a microtubule associated protein that localizes along the length of the microtubule. It is thought that the balance between the activities of these two proteins plays a central role in determining the steady state length of microtubules within a cell. However, it remains unclear how XMAP215 antagonizes the activity of XKCM1. We have developed an assay, using total internal fluorescence microscopy (TIRF), to examine the real-time interactions of recombinant XKCM1-GFP with GMPCPP stabilized microtubules. Confirming previous data, we observe that XKCM1 is highly enriched at microtubule ends. In the presence of XMAP215, this end-binding is abolished, suggesting a potential mechanism for how XMAP215 antagonizes the microtubule destabilizing activity of XKCM1. To explore this question further, we examined the behavior of single XKCM1-GFP molecules while bound to microtubules and observed that XKCM1 undergoes random, 1D diffusion along the microtubule lattice. Similar behavior similar has been seen with MCAK, the human homologue of XKCM1, and it has been proposed that this motion provides a mechanism for the rapid targeting of XKCM1 to microtubule ends. We are currently testing the hypothesis that XMAP215 blocks the diffusion of XKCM1 along the lattice, which

inhibits its ability to localize to microtubule ends, and antagonizes its catastrophe promoting activity.

### Localization of EB1, IFT Polypeptides, and Kinesin II in Chlamydomonas Flagellar Axonemes via Scanning Electron Microscopy

R. D. Sloboda,[1] L. Howard[2]; [1]Department of Biological Sciences, Dartmouth College, Hanover, NH, [2]Dartmouth Electron Microscope Facility, Dartmouth College, Hanover, NH

We are using an FEI scanning electron microscope equipped with a thermionic field emission gun (FEG-SEM) to co-localize in the flagellar axoneme different pairs of polypeptides double-labeled with specific antibodies. This approach provides a new perspective on the morphology of the particles involved in intraflagellar transport (IFT), their association with the axoneme, and their protein composition. The FEG-SEM as configured delivers a resolution of ~5 nm with biological samples when operated at 15 kV. Flagella were isolated from *Chlamydomonas* and extracted with 0.1% NP-40 at room temperature. The resulting axonemes were reacted in solution with various primary antibodies specific for flagellar proteins, washed by sedimentation, and then reacted with gold-labeled secondary antibodies. The labeled axonemes were attached to polyethyleneimine coated coverslips and finally fixed in 1% glutaraldehyde. The samples were then critical point dried, coated with 2-3 nm of osmium using a plasma coater, and imaged at 15 kV. Detection of backscattered electrons (BSE) clearly identifies both 12 and 25 nm gold particles while detection of secondary electrons (SE) provides a conventional SEM view of the labeled axonemes; comparison of the BSE and SE images reveals the location of the gold, and hence the antigens, relative to overall axonemal morphology. *Chlamydomonas* EB1 localizes to the plus ends of the outer doublet microtubules, as expected from previous immunofluorescent data (Pedersen et al. Curr. Biol. 13:1969-74.). IFT particles can be identified that are double labeled with antibodies to either kinesin II and IFT 139 (a complex A polypeptide) or kinesin II and IFT 172 (a complex B polypeptide). Experiments are in progress to determine if single individual IFT particles identifiable by FEG-SEM are composed of both complex A and complex B polypeptides. Supported by NSF MCB-0418877.

### Gli2 and Gli3 Localize to Cilia and Require the Intraflagellar Protein Polaris for Function

C. J. Haycraft, B. Banizs, B. K. Yoder; Department of Cell Biology, University of Alabama at Birmingham, Birmingham, AL

Cilia are projections extending from the surface of many eukaryotic cells that can be either motile or immotile and are constructed through a process termed intraflagellar transport (IFT). *Tg737* encodes an IFT protein required for cilia formation that when disrupted in $Tg737^{\Delta 2\text{-}3\beta\text{-}gal}$ mutants results in 8-10 unpatterned digits on the limbs. The lack of ectopic *Shh* expression in $Tg737^{\Delta 2\text{-}3\beta\text{-}gal}$ mutants along with the formation of multiple non-patterned digits is reminiscent of the phenotype seen in $Shh^{-/-};Gli3^{-/-}$ double mutant embryos and recent data has shown a genetic link between IFT/polaris and *Shh* signaling. In agreement with this data, we find that primary cells isolated from the limbs of $Tg737^{\Delta 2\text{-}3\beta\text{-}gal}$ mutant embryos are non-responsive to exogenous ShhN suggesting that *Tg737* is required for *Shh* pathway activation in the responding cell. Exogenously expressed Gli2 and full length Gli3 are nonfunctional in mutant cells while Gli3 repressor and Gli1 function are unaffected. Additionally, we detect an increase in the relative amount of unprocessed Gli3 in $Tg737^{\Delta 2\text{-}3\beta\text{-}gal}$ mutants. Together these data suggest that IFT/polaris is required upstream of Gli transcriptional activity, likely at the level of Gli processing. Furthermore, our data also suggest a direct role for cilia in this signaling pathway as all three Gli proteins and Sufu, a negative regulator of Gli function and part of the complex involved in Gli processing, localize to the distal tip of cilia in primary limb bud cultures. We propose that the distal tip of the cilia functions as a site for concentrating components of the hedgehog pathway for regulation by proteolytic processing. In the absence of cilia, these proteins are diffusely located and are processed inefficiently resulting in the non-responsive nature of the mutant cells.

### Functional Genomic Analysis of Sensory Cilia from *C elegans*

O. E. Blacque, C. Li, P. N. Inglis, M. R. Leroux; Molecular Biology and Biochemistry, Simon Fraser University, Burnaby, BC, Canada

*C. elegans* is a useful model for elucidating the molecular basis of cilia function and cilia-related diseases such as polycystic kidney disease and Bardet-Biedl syndrome (BBS). For example, we previously showed that the *C. elegans* BBS proteins play important roles in intraflagellar transport (IFT) - a kinesin and dynein driven motility that builds and maintains cilia - by mediating the functional coordination of the two kinesin-2 motors that drive anterograde IFT (Blacque et al., Genes Dev. 18: 1630-1642; Ou et al., Nature 436: 583-587). Specifically, we found that in *bbs* mutants, IFT rafts are destabilized, resulting in the separation of the two kinesin-2 motors and IFT complexes A and B. To identify novel cilia-related components, in particular those associated with BBS and IFT gene pathways, we recently employed functional genomics in *C. elegans* and found many candidate ciliary genes, including a novel IFT component, DYF-13 (Blacque et al., Curr. Biol. 15: 935-941). To extend this work, we have now utilized microarray technology to identify gene targets of the ciliogenic RFX transcription factor, DAF-19. By comparing the expression profiles of wild-type and *daf-19* mutant worms, we identified new candidate cilia-related genes, including a novel conserved IFT-associated gene, which we name IFTA-1. We subsequently generated a deletion allele of *ifta-1* and found that these animals display structural and functional ciliary defects, including a severely abrogated IFT process. Interestingly, *ifta-1* mutant phenotypes are similar to those of *che-11* mutants, suggesting that IFTA-1 is an IFT complex A type protein. Using *bbs* mutants as tools for destabilizing the IFT raft, we are currently employing genetics and fluorescence microscopy to further characterize IFTA-1 function. Furthermore, these approaches may be useful for establishing a genetic model for the assembly of the entire motor-IFT particle complex.

### Intraflagellar Transport Protein IFT27 is a Rab-Like Small G Protein that Functions in the Cell Cycle

H. Qin, Z. Wang, J. L. Rosenbaum; MCDB Dept., Yale University, New Haven, CT

Intraflagellar transport (IFT) is a bi-directional motility system occurring in most eukaryotic flagella/cilia. IFT is required for flagellar formation and maintenance, but whether it has a role in other cellular functions is not known. IFT particles contain multiple proteins forming two complexes, A and B. Here, we report that IFT27, a 27 kD component of IFT complex B, is a Rab-like small G protein. In *Chlamydomonas*, GFP tagged IFT27

moves bi-directionally inside the flagellum. Like other previously-reported IFT particle proteins, IFT27 is also concentrated at the basal body region. However, unlike other IFT proteins, a fraction of IFT27 from *cell body extracts* does not sediment at 16S with the rest of complex B, but rather remains at the top of the sucrose density gradient. In *flagellar* extracts all the IFT27 sediments at 16 S. Surprisingly, when the level of IFT27 protein is knocked down by RNAi, cells no longer divide normally. In such RNAi knock down cells, flagella can be assembled and maintained but multiple basal body sets and nuclei are observed and the cells become very large. The cells often fail to complete mitosis and eventually die. Mutations affecting other *Chlamydomonas* IFT particle proteins result only in flagellar defects; knock down of IFT27 is unique in having an effect on cell division. Currently we are using over-expression, constitutive active and dominant negative forms of IFT27 to further understand how IFT27 functions in the cell cycle. This is one of the first examples of a *bona fide* ciliary protein, IFT27, having a cell cycle regulatory function. (Supported by NIH grant14642 to JLR.)

**Kin5 Knockdown in Tetrahymena Using RNAi**

A. Awan, A. Bell, P. Satir; Anatomy & Structural Biology, Albert Einstein College of Medicine, Bronx, NY

In previous studies [2004: Cell Motil 58:1-9], we demonstrated that Kin5, a homodimeric Kinesin-2 in *Tetrahymena*, is a ciliary protein that showed colocalization with orthologs of *Chlamydomonas* IFT complex proteins along the cilia. Kin5 is an intraciliary transport (ICT) motor distinct from the ICT kinesins, Kin1 and Kin2. In this study, we examined the effect of knocking down Kin5 on ciliogenesis, cell motility and survival, and transport of a putative cargo protein. We devised a modification the standard knockout method to yield a somatic mutant, so that RNA interference (RNAi) can be induced in *Tetrahymena.* We demonstrate that an RNAi construct for *KIN5* has been stably integrated into the genome, such that with appropriate induction, while control proteins are unaffected, Kin5p is severely downregulated and disappears from the cilia. Because Kin5 is an essential component, cell motility decreases by 95.3% and knockdown is lethal by 12 h. However, unlike Kin1p/Kin2p knockout, the Kin5p knockdown does not cause ciliary resorption, while deciliation in the knockdown condition reveals that ciliary axonemes assemble and remain motile in the absence of ciliary Kin5p. Since axonemal construction seems unaffected, we examined whether specific intraciliary non-axonemal cargos might be affected by the knockdown. We chose a protein, Gef1, related to yeast Sec7, a guanine nucleotide exchange factor, that is found in ciliary membrane-matrix fractions and that localizes along the cilium. Gef1 coimmunoprecipitates with Kin5. Nevertheless, Gef1 remains in the cilium under conditions where ciliary Kin5 disappears. Upon deciliation, Gef1 immunofluorescence is absent in the regenerating cilia of the knockout cells. This suggests that Gef1 and similar cargos could be transported into the cilium by the Kin5 complex, and then released into a position along the cilium, where they could act in signal transduction pathways to affect motility and/or viability.
